ENCYCLOPÆDIA BRITANNICA.

Reid.

REID, DR THOMAS, a distinguished Scottish philosopher, and founder of the school of Natural Realism, was born on the 26th of April 1710 at the manse of Strachan in Kincardineshire, a parish about twenty miles from Aberdeen, where his father, the Rev. Lewis Reid, was minister for fifty years. His mother was Margaret Gregory, daughter of David Gregory, Esq. of Kinnairdie in Banffshire, and one of twenty-nine children, the most remarkable of whom were David, James, and Charles Gregory, then professors of astronomy and mathematics at Oxford, St Andrews, and Edinburgh. By his father, Thomas Reid could look back on a long line of ancestors, most of whom had been ministers of the Scottish Church, and with a decided bias towards literature; and in two cases they had forced their way within the shadow of the throne, the one as Greek and Latin secretary, and the other as physician to royalty. On his mother's side he could count the names of men who were as distinguished for their genius as they were illustrious for their worth; and who, by their brilliant talents, had shed lustre on the northern colleges, and left a memorable name in connection with the universities of the south. It was this twofold stream of literature and science that was to combine in forming the philosophy of Reid. Young Reid received his elementary education first at the parish school of Kincardine, and subsequently at Aberdeen. He entered Marischal College in his twelfth or thirteenth year, where, according to his own account, he received an education that was somewhat slight and superficial. He gave no indication of future eminence, but displayed a modest perseverance in study which amounted almost to a passion. About a century before, one of his ancestors had left an endowment to the librarian of his college; and to this office Reid had the good fortune to be appointed. He could now indulge his love of study amid the calm of an academical retreat. Like his great German rival and contemporary Kant, he at first showed a decided predilection for mathematical pursuits, a taste which was confirmed and strengthened by his familiar intimacy with John Stewart, subsequently professor of mathematics in the same college, and author of *A Commentary on Newton's Quadrature of Curves*. The two youths read mathematics with ardour, and studied the *Principia* with fascination.

VOL. XIX.

Reid.

In 1736 Reid resigned his office as librarian, and accompanied his friend Stewart on an excursion to England. They visited London, Oxford, and Cambridge, and made the acquaintance of many persons of the first literary and scientific distinction. On Reid's return to Aberdeen, he was presented by King's College to the living of New Machar, in the same county. The popular prejudice was not, however, in his favour; yet he completely disarmed the animosity of the people by the forbearance of his temper and his active spirit of humanity, and so endeared himself to them that they afterwards said, "we fought *against* Dr Reid when he came, and would have fought *for* him when he went away." He seems to have had an aversion at this time to original composition; and it is recorded of him that he preached the sermons of Tillotson and Evans for years after he became a clergyman. The greater portion of his time was spent in intense study, chiefly of a metaphysical cast, and when he took any relaxation it was for the most part in the shape of gardening and botany. A paper which appeared in the London *Philosophical Transactions* for 1748, entitled "An Essay on Quantity, occasioned by reading a Treatise in which Simple and Compound Ratios are applied to Virtue and Merit," will show how far he still clung to his earlier investigations, and to what extent he had realized the larger field which lay beyond. The work alluded to in the title of this paper was the *Inquiry into the Origin of our Ideas of Beauty and Virtue* of Dr Hutcheson of Glasgow, who died the previous year. In 1752 Reid was elected professor of philosophy in King's College, Old Aberdeen, where he required to teach mathematics and physics, as well as logic and ethics. Shortly after his removal to his new sphere of labour, Dr Reid took part in organizing a literary society, which was instrumental during many subsequent years in kindling and fostering that spirit of philosophical research which, in the writings of Reid, Gregory, Campbell, Beattie, and Gerard, reflected so much lustre upon northern literature. The *Inquiry into the Human Mind on the Principles of Common Sense* was published by Reid in 1764, after having received the sanction and applause of his immediate associates. He was then in his fifty-fourth year, and he seems to have meditated this work for twenty-five years, from the publication of Hume's remarkable *Treatise of Human Nature* in 1739.

Reid.

Thus Hume had the unexpected credit of awakening the suspicions of Reid by his sceptical conclusions, as he not long afterwards had of arousing Kant from his "dogmatic slumber." As the refutation of Hume's scepticism was the great object of Reid's *Inquiry*, he took the opportunity of submitting his manuscript, through Dr Blair, to the great sceptic's perusal. Hume, after reading the manuscript, wrote to Reid, "I have read your performance with great pleasure and attention. It is certainly very rare that a piece so deeply philosophical is wrote with so much spirit, and affords so much entertainment to the reader." And again, "I kept a watchful eye all along over your style; but it is really so correct, and so good English, that I found not anything worth the remarking." Reid had unquestionably in this work fallen upon a mine of the very purest metal, and "by an ignorance wiser than knowledge" worked it out with untiring perseverance. It may be fairly questioned, however, whether he was in all respects consistent in his application of the principles of Common Sense to the refutation of the Scepticism of Hume, or of an Idealism more subtle than that of Berkeley. Reid informs us that he "had embraced the whole of Berkeley's system" in the course of his speculative inquiries; and was only withheld from giving it his final approbation on "finding other consequences to follow from it, which gave me more uneasiness than the want of a material world." His reading in philosophy was, to say the least, exceedingly limited; and this limitation had both its advantages and its disadvantages. For, while it kept his mind comparatively free and untrammelled to look at the facts which his consciousness revealed to him, it, by this very freedom, threw him off his guard in analysing the contents of his experience, and deluded him with the conviction, that when he had confuted a doctrine under a particular development, his principles were proof against that doctrine, under whatever guise it might assume. So it was with the doctrine of Idealism, which he hastily identified with the Idealism of Berkeley. He raised, however, a substantial protest against the doctrines which it was his business to refute, and in his future work was more guarded in his expression as well as more circumspect in his estimate of philosophical opinion.

The fame of Dr Reid spread rapidly all over the country; and in 1763 he was invited to Glasgow to fill the chair of moral philosophy, then vacated by Dr Adam Smith. Glasgow at that time presented strong attractions to a man of Dr Reid's habits of mind. Simson, Moor, and Black, were still in the full vigour of their faculties, and were still looking forward to long years of intellectual enjoyment. Animated by the presence and stimulated by the zeal of such associates, Dr Reid entered upon the new scene of his labours with an ardour that was very uncommon at his period of life. Dugald Stewart, who was a pupil of Reid's in Glasgow, and who has left us an elegant *Account of his Life and Writings*, in speaking of his merits as a public teacher, bears the following testimony:—"The merits of Dr Reid as a public teacher were derived chiefly from that rich fund of original and instructive philosophy which is to be found in his writings, and from his unwearied assiduity in inculcating principles which he conceived to be of essential importance to human happiness. In his elocution and mode of instruction there was nothing peculiarly attractive." "A brief Account of Aristotle's Logic, with remarks," appeared in 1774, from the pen of Dr Reid, in the second volume of Lord Kames's *Sketches of the History of Man*. In 1781 Reid resolved to retire from his public duties, and to devote himself, while his health and faculties would permit, to the further elucidation of the phenomena and laws of the human mind. Although at that time upwards of seventy, neither in vigour of body nor of mind did he seem to have sustained any injury from time. He published his *Essays on the Intellectual Powers of Man* in 1785; and his *Essays*

on the *Active Powers of Man* appeared in 1788. This last performance may be said to have closed his literary career, for, with the exception of short occasional essays on subjects which happened to interest him, written for a philosophical society of which he was a member, it was the last work he ever wrote. His active and useful life was now drawing to a close. He was seized with a violent disorder in the month of September 1796, and after a severe struggle he died on the 7th of the following month, in the eighty-seventh year of his age.

Dr Reid, though somewhat under the middle size, was uncommonly muscular and athletic,—advantages to which his habits of temperance and exercise, as well as the extreme evenness of his temper, contributed not a little. In private he combined the dignity of the philosopher with the amiable modesty and gentleness of the child. His philosophical genius was peculiarly distinguished by a singular patience of thought, and by a cautious discriminating judgment. He was endowed by nature with a disposition, which early worked itself into a habit, of rivetting his most fixed and concentrated attention on his own mental operations; and though there have been men who, with such a disposition, would unquestionably have drawn from the evanescent sphere on which he fixed his contemplation results more brilliant and conclusions more startling, yet it remains a question whether a loftier genius would have outshone Reid in the ultimate task of photographing, so to speak, the phenomena of the human consciousness, and of cautiously attending to what that consciousness implied. He was by no means a brilliant thinker; but no philosopher ever surpassed him in patience. His style was simple, easy, and familiar; and perhaps his works have suffered somewhat from not being written in a language more elaborately technical, or at least in a manner less readily accessible to the ordinary comprehension of men. Since Reid's time the estimates of his philosophical capacity have been alike curious and various. Some would have him endowed with a commanding genius, at whose light darkness became visible, and before whose glow all things false were consumed; others would degrade him beneath the dignity of the philosophical class, and have men believe he had no business among philosophers. Extravagant as these estimates must appear, they might perhaps find an explanation in the mode of writing which the author adopted. To the one class, not very discriminating, his simple and familiar language would at once declare him the man of genius; while with the other class, equally indiscriminating, the absence of rigorous and severe technicality would at once erect a barrier between his talent and their appreciation. Suffice it to say, that his philosophy of Common Sense, his theory of external perception, still holds ground amid the war of conflicting systems and the general uprooting of opinion; and so far as one can observe amid the din and dusky confusion attendant on the strife, it is a philosophy, or, if men will, a bundle of theories, which is likely to outlive the rough weather of human speculation for a considerable time to come. The polemic which Reid implicitly or explicitly carried on was of a twofold character, and the method which he brought to it was in some measure peculiar. In the first place, it was against the *Scepticism* of Hume he directed his primary and ineradicable beliefs; and in the second, it was at the *Idealism* of Berkeley he aimed his principles of the common sense. Hume, as a sceptic, who knew well the functions he had to fulfil, accepted the premises afforded him by the sensationalists, and carried these premises to their legitimate conclusions. These conclusions, as all know, were one weltering, chaotic sea of the wildest doubt; and the fatal reflection regarding the whole of his speculations was, the perfect legitimacy of his polemic, and the absolute justness of his reasoning. It was obvious that if

Reid.

Reid. Philosophy was again to raise her cloven front before the altar of truth, she must disrobe herself of her meretricious attire, and be content to adorn her person in the simple and severe dress of a handmaid. Thomas Reid saw this truth, to the extent of his vision, and resolved to make the most of it. He would avoid the hollow empiricism which had so greatly degraded his century; and he would shun the extravagant folly of aspiring to a speculative ontology on which so many have made shipwreck. The method which he accordingly adopted was that of observation and experiment, of the analysis of the contents of his inner consciousness; in a word, the method of Induction. Such was his method, and such was his design. It was nothing less than the re-construction and re-establishment of the entire speculative edifice, which, in such an humbling and confounding manner, lay level with the ground. He at once assailed the Idealist and the Sceptic in his doctrine of External Perception; and he entirely confounded the latter by his metaphysical theory of the laws of Substance and Cause. He reduced perception to an act of immediate or intuitive cognition, viewing the one total object of perceptive consciousness as real, and founding the doctrine on the spontaneous consciousness or common sense of mankind. He thus instituted the doctrine of *Natural Realism*, as Sir William Hamilton calls it, to oppose the Idealists, whether absolute like Berkeley, or hypothetical, like the great body of philosophers before his time. Reid may have fallen upon this doctrine by his very ignorance of the literature of philosophy. Of the great principle first explicitly announced by Empedocles, and hitherto assumed by philosophers, that "the relation of knowledge inferred an analogy of existence," Reid, in dealing with Norris, professes his entire ignorance. "This argument," he says, "I cannot answer, because I do not understand it." Thus at least was Reid saved from one great snare which lay on the beaten path to External Perception. But in the further pursuit of scepticism, Reid, on analysing the contents of his observation of the metaphysical laws of Substance and Cause, found that, so far from those principles being entirely deducible from experience, as had hitherto been alleged, they were emphatically of that nature of which experience could give no account at all. Here, again, like the great German critic Kant, he was forced to avow that, while all knowledge began with experience, all knowledge was not therefore necessarily derived from experience. He ascribed those laws to the primary and fundamental beliefs which the mind had brought with it to the observation of phenomena; and without taking account in any very precise way as to whether the Reason in which those radical convictions inhered was personal or impersonal, he left the conviction on the mind of the reader that the principles of Substance and Quality, of Cause and Effect, &c., could not with safety be carried beyond the sphere in which human experience is possible. Thus, again, his philosophy is antagonistic to speculative ontology under every form, whether of a more abstract and indeterminate shape, such as Spinoza, Hegel, and Schelling have promulgated, or whether of a less abstract and more determinate nature, as in the modern speculations of M. Cousin. Reid's philosophy partook to a considerable degree of the modesty of his character. As he knew well that an uneasy vanity was generally inconsistent with true wisdom, so a kindred instinct seems to have taught him a genuine philosophical sagacity. Not that he exhibited throughout that clear seizure of the truth and complete self-consistency, which would have rendered his works immaculate and his conclusions impregnable; but Sir William Hamilton has since thrown his opinions under a much greater light, both of learning and speculative genius, than Reid could pretend to; harmonizing what was discordant, giving definite shape to what was before obscure, inserting useful distinctions, and com-

pleting what the author had only dimly apprehended or but imperfectly grasped. (For further information regarding Reid and his philosophy, the reader is referred to Hamilton's edition of his works. Casual information respecting the philosophy of Common Sense will occasionally be found in the *FIRST PRELIMINARY DISSERTATION* of Dugald Stewart, prefixed to the present work.) (J. D.—s.)

REID, *Sir William*, distinguished for his success in physical science and in civil administration, was born in 1797, at the manse of Kinglassie, a village in Fifeshire, and entered the army in 1809 as a lieutenant of Royal Engineers. The first part of his career was passed in unobtrusive though active service. He passed through the heat of the French war under the Duke of Wellington, playing his part in most of the onsets, and bringing away several wounds. His next important engagement was at the bombardment of Algiers in 1816. He is then found in Barbadoes in 1832 as major of the engineers who were re-erecting the government buildings. It was not until 1838 when, with the rank of lieutenant-colonel, he was governing Bermuda, that Reid began to come prominently before the public. In that year he published his *Law of Storms*, the first result of a course of patient and sagacious observation. He continued to test and mature his views while holding the governorship of the Windward Islands; and published in 1849 *The Progress of the Development of the Law of Storms*. The fame of these publications, as well as his growing reputation for administrative talent, gave him a high standing on his return home, and led him to several distinguished honours. In 1851 he was appointed chairman of the executive committee of the Great Exhibition. No sooner had that important task been finished than he was made a K.C.B., and sent out to govern Malta. There, too, his vigorous and spirited rule gained for him distinction; and he had just returned home with the title of major-general when he died in October 1858.

REIGATE, a parliamentary borough and market-town of England, in the county of Surrey, stands near the Mole, at the foot of the southern slope of the North Downs, 21 miles S. by W. of London. This small, neat town consists of one main street, running from E. to W.; and has a town-hall in the market-place, occupying the site of an old chapel of St Thomas à Becket. The church, which is built of limestone, at various dates, but chiefly in the perpendicular style, has a lofty embattled tower, and contains the tomb of Lord Howard of Effingham, who commanded the English fleet against the Armada. Besides this and a district church, built in 1845, there are in Reigate places of worship for Independents and Quakers. A grammar school, national and infant schools, literary institute, and a savings-bank are among the other establishments of the town. Some earthworks mark the site of a castle, which was destroyed in 1648. Under the court of the castle is a cavern where the barons are said to have met to draw up the Magna Charta. Of a priory that formerly stood here there are now no remains. Reigate returns one member to Parliament. Pop. (1851) 4927.

REIMARUS, HERMANN SAMUEL, a German, who was born at Hamburg in 1694, and was educated at the university of Wittenberg, is distinguished for his services in several departments of learning. His first fame was gained as the author of *Primitia Wismariensia*, 4to, 1723. Then, settling down at Hamburg in 1727 as professor of philosophy, he became one of the brightest ornaments of the university of that city. His marriage in the following year with the daughter of J. A. Fabricius was the means of introducing him into other fields of labour. He assisted that eminent scholar in preparing his philological works; and after his death he published a Latin memoir of him, 8vo, Hamburg, 1737. Nor did a delicate constitution, and the growing infirmities of age, prevent him from entering

Reid
||
Reimarus.

Reims
||
Reiske.

upon the new study of natural history. He published *Observations, Physical and Moral, on the Instinct of Animals*, in 2 vols. 12mo, Hamburg, 1760. Other researches on the same subject would also have appeared had not death, in 1768, cut short his career. The other works of Reimarus are,—*A Letter to Cardinal Quirini concerning the Works of Dion Cassius*, 4to, Hamburg, 1746; *The Roman History of Dion Cassius*, in 2 vols. folio, Hamburg, 1750–53; and *A Discourse on the Principal Truths of Natural Religion*, 8vo, Hamburg, 1754, a popular treatise, of which a seventh edition appeared in 8vo, 1798. He is also the reputed author of the famous *Wolfenbützel Fragments*, published by Lessing in 1774 and 1777.

REIMS. See RHEIMS.

REINESIUS, THOMAS, a learned German, was born at Gotha in 1587, and studied medicine at Wittenberg and Jena. After travelling in Italy, and practising in various towns in Germany, he is found at Leipsic in the former half of the seventeenth century enjoying a high reputation. His erudition and critical sagacity in questions of classical lore were admitted to be extremely great. The many philological works which had issued at intervals from his pen had carried his name far and wide, and raised up many admirers. Louis XIV. of France sent him many tokens of regard and esteem. Several eminent contemporaries were in the habit of consulting him on subjects of learning. Especially was he considered an oracle in medicine and archæology. Reinesius died on the 17th January 1667. The following are some of his works:—*Variarum Lectionum Libri Tres Priores*, in 4to, Utrecht, 1640; *Observations upon Petronius*, in 8vo, Leipsic, 1666; *Epistolæ*, in 4to, Jena, 1670; and *Syntagma Inscriptionum Antiquarum Omissarum in Opere Jani Gruteri cum Indice*, folio, Leipsic, 1682.

REINHOLD, ERASMUS, an eminent German mathematician, was born in 1511 at Saalfeld, and was determined towards mathematics at the university of Wittenberg. Appointed to the mathematical chair in his *alma mater*, and favoured by the patronage of Albert, Duke of Prussia, he devoted himself to the prosecution of his favourite science. With patient and careful labour he began to produce a series of works of great practical utility. The first book of the *Almagest*, in Greek, with a Latin version and scholia, was issued in 8vo, 1549. A set of astronomical tables, formed from a comparison of the observations of Copernicus with those of Ptolemæus and Hipparchus, and called, in honour of his patron *Prutenicæ Tabulæ Cælestium Motuum*, was published in 1551. In 1554, the year after his death, there appeared a work entitled *Primus Liber Tabularum Directionum*, in which he extended Regiomontanus's Table of Tangents to each minute of the quadrant. There were also other calculations of his which were printed a considerable time after his decease.

REISKE, JOHANN JACOB, a profound scholar and eminent critic, was born in the year 1716 at a small town in the duchy of Anhalt in Germany. His parents occupied an humble situation in life; and in consequence of the narrow circumstances in which he was placed, he had many difficulties to struggle with during the early part of his career. These, however, he surmounted by unabating perseverance; and in 1733 went to the university of Leipsic, where he remained during five years in the ardent pursuit of his studies. Here he acquired an extensive knowledge of the Arabic, and engaged in the translation of a book from that language, which was afterwards published. With the view of prosecuting to greater advantage the study of Arabic, which had become with him a passion, he travelled on foot to Leyden, where new difficulties attended him. Whilst he remained there he was employed in arranging the Arabic manuscripts belonging to the university; and for this labour he received a very small compensation. During his residence at Leyden part

of his time was occupied in the translation of various essays from the German and French languages into Latin. These essays afterwards appeared in the *Miscellanea Critica*. About the same time also he translated into Latin the whole of the *Chariton* from the Greek, and the *Geography* of Abulfeda from the Arabic. Having spent eight years at Leyden, Reiske was driven from this place by jealousy and calumny, which, it is said, were excited against him chiefly by the younger Burmann, in consequence of his critical strictures on the edition of Petronius published by that author; but before his departure from this learned seminary he had obtained the degree of Doctor of Physic, which was conferred in a manner highly to his honour. He afterwards visited different parts of Germany, and at last settled a second time at Leipsic, where he remained for twelve years. But although he had received the appointment of professor of Arabic, the emoluments of his office were so scanty that he had still to struggle with all the difficulties attendant on poverty, and, to procure a subsistence, was obliged to engage in humble employments of literary labour, and submit to the severe and ill-requited drudgery of editing works for booksellers, or contributing detached papers to periodical publications. About this time the *Acta Eruditorum* were greatly indebted to the labours of Reiske. But in the midst of all the difficulties and hardships now alluded to he prepared and published a work of profound learning and great merit. This work, which extended to five volumes, appeared under the title of *Animadversiones in Auctores Græcos*, and added much to our author's reputation. In the year 1758, in consequence of the death of Haultausius, he obtained a situation which was not only honourable, but lucrative. This was the place of rector of the college of St Nicolas in Leipsic, in which he continued during the remainder of his life. He was now raised above want, and being free from the difficulties and embarrassments which had hitherto constantly attended him, he was thus enabled, in the midst of learned ease, to prosecute his favourite studies.

In the year 1764 Reiske married Ernestine Christine Müller, a woman of great learning, and of whom it is said that her knowledge, especially in Greek literature, was little inferior to that of her husband. In all his literary labours she was a useful associate; but the assistance which she contributed to his great work, the edition of the Greek orators, was particularly valuable. He died in 1774, possessing a very distinguished reputation as a scholar and critic. The number of works which he superintended and published was very great. A complete list of them is given in the continuation of his memoirs by his wife, published at Leipsic in 1783.

RELAND, ADRIAN, an eminent orientalist, born at Ryp in North Holland in 1676, where he evinced early an extraordinary degree of talent for literature and science. He studied under Surenhusius for three years, where he made extraordinary progress in oriental languages and literature. He was elevated to the chair of philosophy at Hardwick before he had completed his twenty-fifth year. He subsequently exchanged his philosophical professorship for that of oriental languages and ecclesiastical antiquities at Utrecht. He died of small-pox on the 5th of February 1718, in his forty-second year.

The principal works of Reland are:—*Palæstina ex Monumentis veteribus illustrata*, 2 vols., Traject. 1714,—unquestionably his greatest work, and still spoken of with great respect by the best writers on the subject; *Dissertationes quinque de Nummis Veterum Hebræorum*, 1709; *Dissertationum Miscellanearum*, 4 vols., 1706–1708; *De Religione Mohammedica*, Ultraj. 1705; *De Spoliis Templi Hierosolymitani in Arcu Titiano Romæ conspicuis*, Traject. 1716. The remaining works of Reland were chiefly Latin poems and orations.

RELIEF, in sculpture is the projection or standing out of a figure which arises prominently from the surface on

Reland
||
Relief.

Relief
||
Rembrandt

which it is formed, whether that figure be cut with the chisel, moulded, or cast. There are three kinds or degrees of rilievo,—alto, basso, and demi-relievo. The alto-relievo, called also *high-relief*, is when the figure is formed after nature, and projects as much as the life. Basso-relievo, bas-relief, is when the work is raised a little from the surface, as in medals and the frontispieces of buildings, but particularly in the histories, festoons, foliages, and other ornaments of friezes. Demi-relievo is when one-half of the figure rises from the plane. When in basso-relievo there are parts that stand clear out, detached from the rest, the work is called a demi-basso. In architecture the relief or projection of the ornaments ought always to be proportioned to the magnitude of the building it adorns, and to the distance at which it is to be viewed.

RELIEF, in painting, is the degree of boldness with which the figures appear, at a due distance, to stand out from the ground of the painting.

RELIGION (*religio*) is a word, derived, according to Cicero (*De Natura Deorum*, lib. ii. 28.), from *relegere*, to re-consider; but, according to Servius and most modern grammarians, from *religare*, to bind fast. The reason assigned by the Roman orator for deducing *religio* from *relego* is in these words:—"But those who are called religious (*religiosi*), from their habit of considering carefully (*relegendo*), should diligently weigh everything which pertains to the worship of the gods, and, as it were, re-consider (*relegerent*) it." The reason given by Servius for his derivation of the word is, "that religion binds the mind fast." If the Ciceronian etymology be the true one, the word *religion* will denote the diligent study of whatever pertains to the worship of the gods; but, according to the other derivation, which we are inclined to prefer, it denotes that obligation which we feel on our minds from the relation in which we stand to some superior power. The import of the word religion is different from that of theology, since the former signifies a number of practical duties, and the latter a system of speculative truths. (See THEOLOGY.)

REMBANG, a town of Java, capital of a province of the same name, on the N. coast of the island, 60 miles E.N.E. of Samarang. It is a thriving, bustling town, with ship-building and salt-pans, an active navigation and trade, especially in ship-timber. The harbour is safe and good; and the town has a fort, mosque, school, hospital, &c. Pop. 8000.

The province, which is bounded on the E. by that of Surabaya, S. by those of Kediri and Madiun, W. by that of Samarang, and N. by the Java Sea, is generally hilly, and watered by the Solo, flowing eastwards. By far the most of the surface is barren, and much of it covered with date forests. Besides timber, rice and tobacco are among the productions. Pop. 460,000.

REMBRANDT VAN RHIN, the name by which PAUL GERRETZ is usually known, was a very distinguished painter and engraver, and was the son of Hermann Gerretz, a miller, who dwelt on the banks of the Rhine, between Leyderdorp and Koukergeren, near Leyden, where he was born in 1606. His father, who was in tolerably easy circumstances, was anxious for the youth to study Latin, and to adopt ultimately some learned profession. Rembrandt thought otherwise; and in place of studying Latin at Leyden, as was his filial duty, he spent his time in drawing Dutch boors and in delineating rotund bar-maids. It was clear that Rembrandt would be a painter; and his father accordingly placed him with Jacob Van Zwaanenberg at Amsterdam, where he spent three years. According to all accounts, his progress during this initiatory stage was the perfect astonishment of his master. He is said to have passed some time also with Peter Lastmann and Jacob Pinas, in order to perfect himself in the mechanical details of his art. Leaving the studio of Pinas, he commenced work on his own account within the precincts of his father's

mill. In the objects of nature which surrounded his locality, and the grotesque specimens of Dutch peasants which his neighbourhood afforded, he found nourishment for his taste for simplicity, and food for his genius. He worked with great diligence, and rapidly acquired both fortune and fame. In 1630 he settled in Amsterdam, where he resided during the remainder of his life. He married in 1634, soon after reaching the city, a handsome peasant girl of Ramsdorp, whose portrait he has frequently painted. From his first establishment in Amsterdam he met with the most flattering attention. The grandest personages of the Dutch city would have their portraits taken by no one but Rembrandt; all the art students who could muster the requisite fee (for Rembrandt loved money dearly) came and laid it at the feet of this rising Dutch artist. We must not suppose, however, that Rembrandt entirely deserted the ways of those Rhine peasants or their rustic sports, upon his making the acquaintance of such distinguished personages, and on his being able to count his pupils by the dozen. The quaint old mill no longer enlivened him with its pleasant clack, and his eyes no longer rested on the queer figures which moved on the banks of the Rhine. Yet he spent his hours of recreation among the lowest orders of the people, whom his pencil delighted to portray, supplying his capricious fancy with its appropriate stimulant, and finding his ideals of the beautiful among the squat, sturdy Dutchmen who were wont to while away the time amid the congenial flavours of a beer-house. He sought nature in her simplicity; and she seems to have found her way to Rembrandt, despite his occasional irreverence for the antique. He was wont to amuse his disciples by introducing them to his collection which was designed to illustrate the ancient style. This consisted of a great variety of old armour, sabres, flags, and fantastical vestments. There was just a slight degree of affectation in this, as there usually is. Rembrandt was the most illustrious artist of his time; and he continued with unabated ardour to practise his delightful art, until death came to summon him away from Amsterdam. In the registry of burials, in the Wester Kirk of that city, there is the following entry, which has recently been discovered:—"Tuesday the 8th of October, 1669, *Rembrandt Van Rin*, painter, on the Roosegracht, opposite the Maze, leaving two children." This record places the date of his death beyond dispute; but men are likely still to cavil regarding the exact place and date of his birth. Very little is known of his life. At his death he seems to have shared the humble lot of those with whom he for the most part associated; labour and comparative obscurity while living, and at death forgetfulness. The great world, however, would not have him be forgotten. The sons of genius are sons of fame. The burgomaster Six was the only man of rank with whom Rembrandt associated; and the landscape "*De la Moutarde*" is said to have been the result of a wager between the painter and his host. The best and the most recent account of the life and merits of Rembrandt is to be found in a lecture in Dutch, by P. Scheltema, published at Amsterdam in 1853. The reader may likewise consult his *Life and Works*, by J. Burnet, 1848.

Rembrandt Van Rhin stands distinguished from all artists of note by the boldness of his style, his daring manner of colouring, and his distribution of light and shade. His historical figures are doubtless deficient in dignity; but there is in them an eminent degree of truthfulness. While entirely regardless of beauty of person or elegance of deportment in his principal characters, he is eminently careful that every individual in his painting should have the varied expression of passion or sentiment appropriate to his situation. Colour, in all its combinations and gradations, was with Rembrandt the paramount consideration. His landscapes are obscured by a dusky twilight; and forms are rendered apparent in them by a struggling

Remire-
mont
||
Remo.

gleam of light which has forced its way through the sullen gloom. Rembrandt's great power, however, lay in portraits. In this department he had no equals among the Dutch painters, and few of any other school could rival him in simplicity, truth, and force of expression. As a historical painter, his figures are frequently ignoble; and he seems occasionally to have courted vulgarity rather than the graces. In the handling of his portraits he varies considerably. In the portraits of ladies particularly he seems to have exercised the most scrupulous care and attention; while in his portraits of the other sex he for the most part indulges his freedom to the fullest extent, sometimes running into positive coarseness. Fuseli says of him (Lecture ii.) that he was "a genius of the first class, in whatever relates not to form. In spite of the most portentous deformity, and without considering the spell of his chiaroscuro, such were his powers of nature, such the grandeur, pathos, or simplicity of his composition, from the most elevated or extensive arrangement to the meanest and most homely, that the best cultivated eye, the purest sensibility, and the most refined taste dwell on them, equally enthralled."

Rembrandt was likewise a very eminent engraver as well as a most original painter. He was the inventor of a process which throws an indescribable charm over all the productions of his brilliant burin. His etchings evince the most extraordinary facility, and display the most consummate knowledge of the effect of light and shadow. His most remarkable portraits are those of the burgomaster Six, Van Coppenol the writing-master, Van Thol the advocate, Uytenbogaert the minister, and Uytenbogaert the gold-weighter. England is very rich in Rembrandt's works, particularly the National Gallery in London.

A complete catalogue of Rembrandt's works was published by Daulby, Liverpool, 1796; and another and more perfect one by Bartsch, Vienna, 1797. Reference may also be had to Nieuwenhuys's *Review of the Lives and Works of the most eminent Painters*, and to Smith's *Catalogue Raisonné*, vol. vii. The latter book contains a very ample, interesting, and instructive account of Rembrandt's paintings and etchings. (See ARTS, *Fine*, and PAINTING.)

REMIREMONT, a town of France, capital of an arrondissement in the department of Vosges, on the left bank of the Moselle, at the foot of the Faucilles Mountains, commanding a fine view of the wooded heights of the Vosges, 17 miles S.E. of Epinal. It has broad and regular streets, lined with houses, ancient, low, and generally ill built. The parish church is a fine edifice in the Italian style; there is too a college, public library, hospital, and law court. Cotton, paper, leather, iron, and steel are among the manufactures of the place; and there is some trade, especially in cheese, timber, cattle, iron, and hemp. Pop. 5103.

REMISCHEID, a town of Prussia, province of the Rhine, in the government and 18 miles E.S.E. of Düsseldorf. It is remarkable for its steel and iron forges, and manufactures of cutlery and hardware, which are exported to various foreign countries. The value of such goods annually produced here, and at Solingen, not far off, is more than L.200,000. Pop. of the town itself, 1800; but including the surrounding district (*Bürgermeisterei*), 13,232.

REMO, SAN, a seaport of the kingdom of Sardinia, capital of a province of the same name, in the division of Nice, on the slope of a hill densely covered with olive trees, that rises from the sea, 30 miles E. of Nice. It stands in one of the mildest parts of the beautiful coast; and is surrounded by gardens, where palms, orange, and lemon trees luxuriantly flourish, and where the sweetest flowers during the summer shed their fragrance around. Viewed from the sea, the town rises triangularly from the shore to an apex on the heights above; the upper and more ancient portion has narrow, crooked, and extremely steep streets, while below there is a handsomer and more modern quarter.

There are several churches and convents, a college, and a good picture gallery in the town. The harbour is small; but some trade is carried on in the produce of the country with Genoa, Marseilles, and other places. Pop. 9854.

REMONSTRANTS. See PREDESTINATION.

REMPHAN, or REPHAN (Ῥεμφάν, Ῥεφάν), a name quoted in Acts vii. 43, from Amos v. 26, where the Septuagint has Ῥαιφάν for the Hebrew *Chum*. It is clear that the Septuagint held the original to be a proper name, in which interpretation our own and most other versions have concurred. But this is by no means clear; for, according to the received pointing, it would better read, "Ye bore the tabernacle of your king (idol), and the statue (or statues) of your idols, the star of your god, which ye make to yourselves;" and so the Vulgate, which has "Imaginem idolorum vestrorum." According to this reading, the name of the idol so worshipped by the Israelites is in fact not given, although the mention of a star still suggests that some planet is intended. Jerome supposes it may be Lucifer or Venus. But the Syriac rendering is, "Saturn your idol," who was worshipped by the Semitic nations along with Mars as an evil demon to be propitiated with sacrifices. This now seems to be the general conclusion, and Winer indeed treats the subject under the head Saturn. It has been alleged, but not satisfactorily proved, that Remphan and Rephan were Egyptian names of the planet Saturn. They indeed occur as such in the Coptic-Arabic Lexicon of Kircher (*Ling. Egypt. Restit.*, p. 49; *Ædip. Egypti*, i. 386); but Jablonsky has long since shown that this and other names of planets in these lexicons are of Greek origin, and drawn from the Coptic versions of Amos and the Acts. (Jablonsky, "Remphan Ægyptior.," in *Opusc.* ii. 1, sq.; Schræder, *De Tabernac. Molochi et Stella Dei Remph.* 1745; Maius, *Dissert. de Krum et Remphan*, 1763; Harenberg, *De Idolis Chum et Remphan*, 1723; Wolf, *Dissert. de Chum et Remph.* 1741; Gesenius, *Thesaurus*, pp. 669, 670.)

REMUS. See ROMAN HISTORY.

RÉMUSAT, JEAN PIERRE ABEL, a celebrated orientalist, was born at Paris on the 5th of September 1788. A severe fall which he received in infancy, and which kept him lying on his couch for several years, was the means of making him a student. Cut off from all the engrossing bustle of life, his mind eagerly sought for amusement and interest in books. The severest studies became in course of time mere pleasant exercises. English history, botany, and Latin were mastered with little or no difficulty. His mental activity continued when he went forth again into the world, and began to fit himself for being a medical man. Besides pursuing his professional studies with great success, he applied himself to oriental languages. At length falling in with a magnificent Chinese work on botany, and desirous of being able to peruse it, he began to learn the language in which it was written. With no other aid than Fourmont's Grammar he accomplished the task in the course of five years; published his *Essai sur la Langue et la Littérature Chinoises* in 1811; and at the age of twenty-three appeared before the world as a Chinese scholar. The great acquirements of Rémusat soon came to be recognised in different quarters. The academies of Grenoble and Besançon received him among their members. The faculty of medicine at Paris gave him the diploma of doctor at the age of twenty-five. He was also patronized by the great scholar Silvestre de Sacy, and obtained through him the appointment of chief doctor of the hospital of Montaigne. But it was not until the restoration of the Bourbons that the good fortune of Rémusat's career really commenced. The great reputation he had achieved now recommended him for promotion. This was ably seconded by his cringing and selfish policy. A long series of appointments was the result. In 1814 the newly-appointed Chinese professorship

Remon-
strants.
||
Rémusat.

Remy, St
Renaudot.

in the College of France was conferred upon him. Not long afterwards he was entrusted with the cataloguing of all the Chinese works in the royal library. In 1818 he was elected to succeed Visconti in the editorship of the *Journal des Savans*. In 1824 he was appointed keeper of the oriental manuscripts in the royal library. There was in fact almost no end to the snug posts and lucrative sinecures which he obtained. Nor did the revolution of 1830 interrupt the flow of his prosperity. He managed to remain in possession of all his salaries until his death on the 3d of June 1832. Rémusat was a member of the Asiatic Societies of London and Calcutta, and of many other learned bodies.

His principal works are,—*Plan d'un Dictionnaire Chinois*, 8vo, 1814; *Le Livre des Récompenses et des Peines*, translated from the Chinese, in 8vo, 1816; *Mémoire sur les Livres Chinois de la Bibliothèque du Roi*, in 8vo, 1818; *Description du Royaume de Camboge*, from the Chinese, in 8vo, 1819; *Mémoires et Anecdotes sur la Dynastie des Djougours Souverains du Japon*, in 8vo, 1820; *Histoire de la Ville de Khotan*, from the Chinese, in 8vo, 1820; *Recherches sur les Langues Tartares*, in 4to, 1820; *Elements de la Grammaire Chinoise*, in 8vo, 1822; *Deux Mémoires sur les Relations Politiques des Premiers Chrétiens, et particulièrement des Rois de France, avec les Empereurs Mongols*, in 4to, 1822–24; *Mémoire sur la Vie et les Opinions de Lao-Tseu, Philosophe Chinois*, in 4to, 1823; *Recherches Chronologiques sur l'Origine de la Hiérarchie Lamaïque*, in 4to, 1824; and *Mémoire sur Plusieurs Questions Relatives à la Géographie de l'Asie Centrale*, in 4to, 1825. The numerous papers which he communicated to several scientific journals, and to the *Biographie Universelle*, were published under the titles of *Mélanges Asiatiques*, in 2 vols. 8vo, 1825–26; *Nouveaux Mélanges Asiatiques*, in 2 vols. 8vo, 1829; and *Mélanges Posthumes d'Histoire et de Littérature Orientale*, in 8vo, 1843.

REMY, St, a town of France, in the department of Bouches-du-Rhône, on a plain planted with groves of olive trees, 42 miles N.N.W. of Marseilles. It is irregularly built, and has many good houses in an antique style. The best modern edifice is the town-hall; but there are two interesting remains of antiquity,—a triumphal arch and a sepulchral monument, both of unknown date. St Remy has silk-mills, and some trade in corn and wine. Pop. 6024.

RENAIX (Flem. *Ronse*), a town of Belgium, in the province of East Flanders, 20 miles south of Ghent. It has three public squares, with a fountain in each; several churches and schools, a ruined castle, town-hall, hospital, orphan asylum, and other benevolent institutions. The manufactures of the town include cotton, woollen, and linen fabrics; hats, leather, beer, tobacco, chocolate, bricks, tiles, pottery, &c. A large trade in linen is carried on; and besides weekly and monthly markets, there are two annual fairs. Pop. 11,670.

RENAUDOT, EUSEBE, a learned orientalist and ecclesiastical historian, was born at Paris in 1646, and was educated for the church at the Jesuits' College. He first became notable at court as a wonderful young scholar. His exhaustless linguistic knowledge, and the easy way in which he spoke many different languages, drew towards him the regard and confidence of several influential personages. Colbert, the great financial statesman, consulted him upon the project of establishing printing-presses in Paris for the oriental languages. The king himself employed him in various important missions to England, Spain, and other countries. The Cardinal de Noailles likewise took him to Rome in 1700, as his conclavist in the conclave for the election of a Pope. Thus encouraged, Renaudot spent the chief part of his remaining years in illustrating the history and opinions of the ancient churches. His principal works on that subject were,—*Défense de la Perpétuité de la Foi contre les Monuments Authentiques de la Religion des Grecs par Jean Aymon*, in 8vo, Paris, 1708; *Historia Patriarcharum Alexandrinorum Jacobitarum*, in 4to, Paris, 1713; and *Liturgiarum Orientalium Collectio*, in 2 vols. 4to, 1716. Renaudot died in 1720. An English translation of the last of the above-mentioned publications appeared in 12mo, Dublin, 1822.

Rendel
Rendsburg

RENDEL, JAMES MEADOWS, a distinguished civil engineer, was born at a village on the borders of Dartmoor, in December 1799. His professional talents were early developed by various commissions which he received in his native district. Telford, the famous engineer, employed him to lay down considerable lengths of turnpike roads in Devonshire. The Earl of Morley entrusted him with the construction of a cast-iron bridge across the Lary, an arm of the sea within Plymouth harbour. An order was given to him to build a floating steam-bridge for crossing the estuary of the Dart near Dartmouth. He was also engaged in surveying nearly all the harbours on the S.W. coast of England. It was in 1838 that Rendel settled in London, and began to take a high place in his calling. He was soon recognised as a man of accurate observation, sagacious judgment, great professional knowledge, and unwearied energy. The success with which he continued to execute his numerous commissions brought him more and more into repute. At length, in 1843, his engagement to construct the projected docks at Birkenhead was the occasion of bringing him prominently before the public. The enterprise met with opposition; the case was laid before the legislature; and he was summoned as a witness before the parliamentary committees. His learned and lucid evidence, and the able and successful manner in which he maintained his own views, established his reputation as one of the first engineers in the land. From that time he was constantly engaged throughout the country in projecting and conducting large public works. Among his most important enterprises were the dock at Great Grimsby, and the harbours of refuge at Holyhead and Portland. Nor did his talents fail to be appreciated beyond the limits of Great Britain. The Brazilian, the Prussian, and the Sardinian governments in turn employed him to make certain surveys and reports. The viceroy of Egypt appointed him a member of the international commission for examining into the practicability of a canal across the isthmus of Suez. The city of Hamburg too, the year before he died, engaged him to find out some plan of preventing the bed of the River Elbe from being choked up with mud. Rendel, at his death in 1856, was a fellow of the Royal Society, and one of the council of the Institution of Civil Engineers.

RENDSEBURG, a town of Denmark, in the duchy of Holstein, on the confines of Schleswig, stands in a flat, sandy region on both sides of the Eider, and on an island in its centre, 26 miles W. of Kiel, and 54 N.N.W. of Hamburg. It was formerly fortified, but the defences were destroyed in 1852. It is for the most part well built, and consists of three parts,—the old town on the island, the new town on the south or left bank, and the Crown-work (*Kron-werk*) on the opposite side of the river. There are two market-places, two churches, a gymnasium, an arsenal (which contained until recently a great quantity of arms of all kinds), an hospital, house of correction, and custom-house. The manufactures include bells, pottery, tobacco, vinegar, and other articles. The situation of the place is very favourable for trade and navigation. It communicates with the German Ocean by the Eider, and with the Baltic by the Schleswig-Holstein Canal, which joins the river here. There is also a railway from this to Hamburg. In the middle ages the site of the old town was occupied by a castle called Reinoldsburg, which was for a long time alternately possessed by Denmark and Holstein. The date of the first rise of the town is unknown; it was encircled by walls and ditches in 1539. The old town was fortified anew by Frederick III. of Denmark (1669–71), who placed over the Holstein gate the inscription, "Eidora Romani terminus imperii," declaring the Eider to be the limit of the German empire, of which Rendsburg is consequently the most northern town. Additional fortifications were added in 1685, 1690, and 1695, so that the place became

Réné
||
Renfrew-
shire.

a fortress of the second class. In 1848 Rendsburg fell into the hands of the Prussian and Holstein troops; and on being regained by the Danes was dismantled. Pop. 10,000.

RÉNÉ OF ANJOU, commonly known as the "good King René," was born at the castle of Angers in 1409. The first part of his life was remarkable for a course of tantalizing events. He had not long obtained possession of the duchy of Lorraine, in right of his wife, when Anthony, Count of Vaudemont drove him from it. Not long afterwards the intelligence, that his brother Louis of Anjou, and Joan, Queen of Naples, had died, leaving him heir to their dominions, reached him when he was the prisoner of the Duke of Burgundy, and unable to lay hold of his newly-acquired rights. It is true that he was soon released; but fortune still continued to make him her sport. Before he had been four years on the Neapolitan throne, Alfonso of Aragon forced him to leave his crown and flee. He returned to France in 1442, only to find that his territories there were occupied by the English. It was not until after the marriage of his daughter Margaret with Henry VI. of England in 1443 that he was allowed, for the first time in his life, to settle down in undisputed possession of a part of his dominions. This severe course of experience did not prevent René from spending the remainder of his days in sustaining the mock state of a sovereign. Establishing a court in the old castle of Aix in Provence, and keeping up the empty title of King of Naples, the Two Sicilies, and Jerusalem, he conducted himself more like a monarch in a romance than a prince in that troublous and warlike age. Dancing, music, painting, and poetry were his serious business. Troubadours and knights-errant were his only courtiers. If he ever came out among ordinary men and things, it was to superintend some public mime or pageant, or to introduce some luxury among his subjects. So genial and pleasant, indeed, was his rule that, after his death in 1480, the natives of Provence long cherished the memory of the "good King René." As recently as 1823 his statue, wrought in marble by David, was placed in one of the squares of Aix. A graphic account of René is given in Scott's *Anne of Geierstein*.

RENFREW, a parliamentary and royal burgh of Scotland, the capital, but not the largest town, of the county of the same name, near the left bank of the Clyde, 6 miles W.N.W. of Glasgow. The Cart, an affluent of the Clyde, passes close to the town; and there is also a short canal between Renfrew and the Clyde. A single street, with lanes diverging from it, forms the whole town; and the only buildings of importance are the Established church, the Free church, town-house, jail, grammar school (endowed by King Robert III.), and a superior school established in 1842. There is also a library and athenæum. Many of the people are employed in weaving muslin and silk; others in a bleachfield near the town, in ship-building yards, iron foundry, and a distillery in the neighbourhood. There is very little trade, though Renfrew has a quay where the Clyde steamers touch. Weekly markets are held here. The burgh is governed by a provost, two bailies, and nine councillors; and, along with Dumbarton, Port-Glasgow, Kilmarnock, and Rutherglen, sends a member to Parliament. The royal family of Stuart had their earliest possessions in this parish, and the Prince of Wales still bears the title of Baron of Renfrew. Pop. (1851) of the royal burgh, 2722; of the parliamentary burgh, 2977.

RENFREWSHIRE, a county in Scotland, lying between 55.40. and 55.58. N. Lat., and 4.14. and 4.54. W. Long., is bounded on the E. by Lanarkshire, on the S. by Ayrshire, and on the N. and W. by the river and frith of Clyde, which separate it from the shires of Dumbarton and Argyre, excepting a section of about 1300 imperial acres, which is situated on the north bank of the Clyde, opposite the town of Renfrew. Its greatest

length is $31\frac{1}{2}$ miles, and its greatest breadth $13\frac{1}{4}$ miles. Its area is 234 square miles, or 150,000 acres. Notwithstanding the small extent of this shire, its manufactures and commerce render it one of the most important in Scotland.

At the epoch of the Roman invasion, in the first century of the Christian era, this part of Scotland was inhabited by a Celtic tribe, called by the invaders the Damnii. After the withdrawal of the Romans, it was comprehended in the British kingdom of Strathclyde.

The district which now forms the county of Renfrew, at least the greater part of it, was denominated, from one of its rivers, *Strathgryfe* (the valley of the Gryfe), and at one time formed part of the shire of Lanark or Clydesdale. It was the chief patrimony of the great stewards of Scotland, to whom it was granted by the sovereign in the twelfth century. Afterwards it was called the barony of Renfrew, from the burgh of that name, where the stewards long had their principal residence. In 1404, thirty-three years after the accession of the House of Stuart to the Scottish throne, King Robert III. granted this barony, and the other portions of the estates of the steward, to his son and heir James; since which time the eldest son of the sovereign has, besides his other titles, borne that of "Baron of Renfrew." Soon afterwards this barony was erected into a distinct sheriffdom, the courts of which were held at Renfrew till the year 1705, when they were, for convenience sake, removed to Paisley. In 1815 the county was formed into two wards, termed the Upper and the Lower, with a sheriff-substitute for each, Paisley and Greenock being the seats of their respective courts.

Renfrewshire comprehends sixteen entire parishes, besides small portions of those of Beith and Dunlop in Ayrshire, and Govan in Lanarkshire. Two of the parishes, Eaglesham and Cathcart, belong to the presbytery of Glasgow; the other fourteen composed the presbytery of Paisley for a long time prior to the year 1834, when two presbyteries were formed; that of Paisley, consisting of nine of these fourteen parishes; and that of Greenock, consisting of the other five, with the addition of Cumbraces in Buteshire, and Largs in Ayrshire, both of which parishes formerly belonged to the presbytery of Irvine. In the above enumeration of parishes, those which are so *quoad sacra* only have not been taken into account.

About two-thirds of this county, comprehending the western and southern sides, are hilly, the medium elevation being from 500 to 600 feet. Mistylaw, on the west, which is about 1240 feet above the level of the sea, has been represented as the highest hill in the county; but it is now ascertained that a neighbouring height, called the Hill of Staik, is entitled to that distinction, being a few feet higher. Balagieich is one of the highest hills on the south-east side, being about 1000 feet above the sea-level. The hilly district is in general kept in pasture, for which it is better adapted, by the nature of its surface, than for tillage. The cultivated land, which forms a gently-rising district, lies on the north and north-east, and in the centre of the county on both sides of the Black Cart. Of this, the greater part consists of low, detached eminences, which swell in endless variety. These being interspersed with copses, and often watered at the bottom by winding streams, present views remarkable for richness and variety. Indeed, it will be difficult to point to a more beautiful surface anywhere in Scotland. Much of this tract has a close subsoil of small stones and coarse clay, almost impenetrable to water, though there are here many flat holms of great fertility. It is only between Paisley and the Clyde that the country sinks down into a plain, forming the flat district known by the name of "the Laighlands." The length of this beautiful level tract is about 6 miles, its breadth about 3, and its area 12,000 acres. Here the soil is generally a deep, rich

Renfrew-
shire.

Renfrew-
shire.

loam of a dark-brown colour, sometimes of the nature of what is called "cause clay;" and much of it seems to have been formed by the deposition of vegetable mould from the higher grounds. Among the hills in the S.W. there are extensive moors and mosses, the largest being that of Kilmalcolm.

Like the other western counties of Scotland, Renfrewshire has a moist climate, with frequent rains; and the prevailing wind is from the south-west.

Besides the Clyde, which, as has been already mentioned, flows along the northern and western boundaries of this county, the principal rivers are the White Cart, the Black Cart, and the Gryfe. The White Cart, which rises in Lanarkshire, enters Renfrewshire from the south, and pursues a winding course, first westerly towards Paisley, through which it passes, and then northerly towards the Clyde. It is joined at Inchinnan Bridge by the Black Cart, which had previously received the waters of the Gryfe at Walkinshaw, above Barnsford Bridge; and these united streams, which contain nine-tenths of the water of the county, fall into the Clyde about 3 miles below Paisley. By means of a short canal, which was cut to avoid the shallows at Inchinnan Bridge in 1786, the White Cart is navigable up to Paisley. Other improvements upon this river are in progress. Like some other Scottish streams, it was once famous for the pearls which were found in its bed, but these have disappeared since the beginning of the eighteenth century. The Black Cart rises from Loch Winnoch, or, as it is usually called, from an adjoining estate, Castle-Semple Loch, a lake in the south-western extremity of the county. The Gryfe rises in the west, amongst the high lands of the parish of Greenock. The only other stream deserving mention is the Kipp Water, in the west of the county, which falls into the Firth of Clyde at Innerkip. All these streams, and several others of smaller size, independently of their importance to agriculture, are in almost every part of their course applied by the industrious and ingenious inhabitants to the various purposes of manufactures. A ready supply of water is secured by means of reservoirs, some of which are of the size and appearance of considerable lakes; or by enlarging the natural lakes, of which there are many. These streams and lakes contain the kinds of fish that are common in this quarter of the country.

Two important railways traverse the county. Commencing at Glasgow, they have a common line to Paisley, from which the one leads north-westwards to Greenock, and the other south-westwards towards Ayr. There are also railways from Glasgow to Neilston, and from Paisley to Renfrew, and a canal from Glasgow to Johnstone.

The minerals of Renfrewshire are of great importance, and constitute the main source of its manufactures and commerce; but we can only advert to them very generally. Coal, limestone, and sandstone are wrought at Neilston, one of the parishes of the hilly district; and both coal and lime have been found in the flat district near Renfrew. The south-eastern portion belongs to the great western coal region of Scotland; and the many mines which are wrought at Polmadie, on the north-east boundary; at Hurlet, three miles south-east from Paisley, where it has been wrought for more than three hundred years; and at Quarrelton, south-east from Johnstone, give employment to a great number of the people. Limestone abounds in various parts, and is wrought at several quarries. Ironstone, granite, pyrites, alum, &c., are also found. Excellent freestone, lying near the surface, is wrought at various places in the middle district. Greenstone, or, as it is provincially called, *whinstone*, exists in immense masses, along with porphyry, in the west of the county.

The number of proprietors in Renfrewshire is 2610; the amount of real property in 1857, L.282,196; and the valuation of rent for 1857-8, L.315,630. Among the noble-

men's and gentlemen's seats are Hawkhead, belonging to the Earl of Glasgow; Blantyre House, to Lord Blantyre; Pollok, to Sir John Maxwell; Pollok Castle, to Sir Hew C. Pollok; also Castle-Semple, Caldwell, Ballochmyle, &c. There are many remains of ancient structures, which formed the seats of powerful or respectable families. This shire was anciently covered with wood. Even now it is ornamented with many woods and plantations; and it is in general well inclosed.

As an agricultural district, this does not rank so high as some others in Scotland. Hardly more than half the surface is cultivated; but what is so, has the advantage of the best methods. The mode of farming is such as every year to leave more than a half of the arable land in grass, on which the stock chiefly kept is cows, the most part of whose milk is made into butter. There are few cheese-dairies. Out of a total acreage of 75,152, under a rotation of crops in 1857, occupied by tenants paying L.10 rent and upwards, 4765 acres were in wheat, 417 in barley, 17,098 in oats, 1232 in beans, 206 in vetches, 3470 in turnips; 5729 in potatoes, 221 fallow, and 41,598 in grass and hay. In the same year the total number of horses was 3535; of cattle, 22,398; of sheep, 22,477; of swine, 1761; of all kinds of stock, 50,271.

It is by its manufactures and commerce that this county is most distinguished. Goods of silk and cotton, and muslin fabrics, are the principal articles manufactured. Cotton-mills, bleachfields, and printfields furnish employment to a large portion of the inhabitants. Paisley and its environs form the chief seat of the manufactures. At Greenock and Port-Glasgow the foreign and coasting trade of the county, and indeed a great proportion of the foreign trade of Scotland, are carried on.

According to the census of 1851, the county contained in all 128 places of worship, with 82,514 sittings. Of the former, 32 belonged to the Established Church; 29 to the Free Church; 21 to the United Presbyterians; 7 each to Independents, Baptists, and Roman Catholics; 6 to Wesleyans; 4 each to Reformed Presbyterians and Latter-Day Saints; 3 to the Evangelical Union; 2 to Episcopalians; 1 each to the Original Secession, the Unitarians, and the New Church; and 3 to isolated congregations. There were also 105 public schools, with 10,355 scholars; and 103 private ones, with 5948 scholars; besides numerous evening and Sunday schools. The total amount of public expenditure on education in Renfrewshire from 1833 to 1857 is L.10,505. The county returns a member to Parliament; and the constituency in 1858 was 2702. The Parliamentary burghs of Paisley and Greenock have each one member. In 1851 the county contained 10,760 inhabited houses. Pop. (1811) 93,172; (1821) 112,175; (1831) 133,443; (1841) 155,072; (1851) 161,091.

RENI, a fortified town of European Turkey, Moldavia, in the Bessarabian territory, ceded by Russia in 1856, on the left bank of the Danube, at its confluence with the Pruth, about 12 miles E. of Galatz. It has a harbour, considerable navigation, and trade in wheat, fish, hides, copper, wax candles, &c. The value of the exports in 1850 was L.38,815; that of the imports, L.35,593. Pop. (1849) 7314.

RENNELL, JAMES, an eminent geographer, was the son of a captain in the artillery, and was born near Chudleigh in Devonshire in 1742. His early distinction was gained in the active service of his country. He first came into note as a fearless and enterprising midshipman at the siege of Pondicherry. He next appeared more prominently as an officer in the Indian army of Lord Clive. His skill and bravery in that capacity soon marked him out for promotion. He was speedily raised to the rank of major. Not long afterwards he was appointed surveyor-general of Bengal, a post which he held until his severe wounds compelled

Reni
||
Rennell.

Rennes.

him to return to England in 1782. Major Rennell, after his re-settlement in his native country, maintained a high place among men of learning. A *Chart of Cape Lagullas*, a *Bengal Atlas*, and a *Map of Hindustan*, had established his reputation as one of the first of English geographers. He was still adding to his fame by the able and thorough way in which he continued his investigations. His mind fixed itself keenly upon every geographical subject that was brought before it. All the provinces of literature were carefully and patiently explored for the needed information. His conclusions were drawn with acuteness and sagacity; and the results of his researches were laid up securely and methodically in his memory. Nor was he less facile in reproducing his acquisitions for the good of the public. He assisted Dr Vincent in writing the *Voyage of Nearchus*. He aided Sir William Jones in some of that great scholar's oriental works. He likewise illustrated Mungo Park's travels by an accurate and elaborate map. At the same time his pen was busily employed in producing independent works of great and standard value. The most important of these were, *The Geographical System of Herodotus*, in 4to, London, 1800; and *Observations on the Topography of the Plain of Troy*, in 4to, 1814. At his death, in March 1830, Major Rennell was an F.R.S. of London and Edinburgh, and a member of the Royal Institute of France and of other foreign societies. He was buried in Westminster Abbey.

RENNES, a town of France, capital of the department of Ille-et-Vilaine, at the foot and on the slope of a hill, at the confluence of the rivers Ille and Vilaine, 60 miles N. of Nantes, and 190 W. by S. of Paris. The latter river traverses the town from E. to W., receiving the other from the N. To the south of the Vilaine stands the old or lower town, to the north the upper or new town, which is the finest portion, having been rebuilt since a conflagration which destroyed it in 1720. These separate quarters are connected by three bridges, and both are surrounded by an ancient wall and towers. Its narrow, crooked streets, and curiously-carved wooden houses, give to the lower town a very picturesque appearance; the other portion, though handsome, is uniformly built of a dull grey stone, and has a sombre aspect. One of the most attractive features of Rennes is its public walks, which are very beautiful: Le Mont Thabor, formed of the garden of an old abbey, commands a fine view over the city and the valley of the Vilaine; Le Mail extends between two canals to the confluence of the rivers. Besides these there are Le Mont de Madame and Le Champ de Mars, all of them being planted with shady trees. One of the ancient gates is still preserved; it is that by which the dukes of Brittany, after taking a solemn oath, entered the city to be crowned in the cathedral. This is now a modern building, large and heavy, with two square towers; the interior, in the Grecian style, is imposing, but has little of an ecclesiastical aspect. Some of the other churches are more tasteful in architecture. The most remarkable edifice of the new town, and almost the only ancient one that has escaped destruction, is the court-house, in which the estates of Brittany used to meet. It contains a large and handsome hall, decorated with paintings and other ornaments. Among the other buildings are the town-hall, a fine modern pile, containing the public offices, library, lecture-rooms, and schools of art and architecture; the theatre, episcopal palace, barracks, and arsenal. There are also in the town several schools, hospitals, and a house of correction. As a manufacturing town, Rennes is not of very much importance, though there is considerable variety in the articles produced. Linen, sail-cloth, hosiery, hats, cordage, fishing-nets, starch, glue, leather, paper, playing-cards, and pottery are the most important of these. The trade, however, is of more extent, and is much facilitated by the situation of the town and its

means of communication, the Vilaine being navigable for barges up to this point, and being connected with the sea by canals leading to St Malo and Brest. Rennes is also connected by canal and railway with Nantes, and so by the latter with Paris. The chief articles of trade are the manufactures of the town, and butter, wax, honey, and poultry, from the surrounding country. Rennes is the seat of a bishop, of a high court of justice, and of a university-academy, besides inferior courts of law. There are large suburbs, which have much resemblance to the town itself. *Condate* was the ancient name of the place, and it was the capital of the tribe called Redones, from whom the modern appellation has been derived. After the fall of the Roman empire it fell into the hands of the Franks; and Clovis established here counts, who seem to have been subject now to the French kings, now to the kings or dukes of Brittany. When Nomenoe, in the ninth century, established the independence of Brittany, Rennes was made the capital, and was fortified as a frontier town against the French monarchy. Along with the rest of Brittany, Rennes came by marriage to the French crown under Francis I. The town has been subjected to several sieges; and at the time of the Revolution was the scene of some conflicts, being always firmly attached to the popular cause. Pop. (1856) 38,945.

RENNIE, JOHN, a distinguished mechanist, architect, and civil engineer, was born on the 7th of June 1761, at Phantassie, in the parish of Prestonkirk, in the county of East Lothian. His father, a highly respectable farmer, died in 1766, leaving a widow and nine children, of whom John was the youngest. The first rudiments of his education were acquired at the village school; and as it frequently happens that some trifling circumstance in early life gives a bent to the pursuits and fixes the destinies of the future man, so it fared with young Rennie. The school was situated on the opposite side of a brook, over which it was necessary to pass by means of a rustic bridge of stepping-stones; but when the freshes were out, the only alternative of crossing the stream was by means of a boat, which was kept at the workshop of Andrew Meikle, an ingenious mechanic, well known in Scotland as the inventor of the thrashing-machine, and many improvements in agricultural implements. In passing through the workshop, which stood on his family property, young Rennie's attention was forcibly drawn to the various operations that were in progress, and a great part of his leisure and holiday time was passed therein. The sons of Meikle and the workmen, seeing the great delight which he appeared to take in examining their labours, were in the habit of indulging him with their tools, and showing him their various uses. His evenings were chiefly employed in imitating those models which had particularly attracted his attention in the workshop; and it is known in the family that, at little more than ten years of age, he had constructed the model of a windmill, a pile-engine, and a steam-engine. That of the pile-engine is still in existence, and is said to be remarkably well made.

Having continued at Preston school till twelve years of age, he had about that time a quarrel with his schoolmaster, whom he deemed incompetent to give him further instruction, and therefore entreated that he might be permitted to leave the school. But his active mind soon became restless; for the first time he felt the hours hang heavily on his hands; and having expressed a wish to be placed under his friend Meikle, he employed himself with this ingenious mechanic for about two years; but his mind expanding with his growth, he began to feel that the progress of his intellectual faculties was likely to be retarded by a constant application to manual labour. He therefore at length determined to place himself under the tuition of Gibson, an able teacher of mathematics at Dunbar, where he soon distinguished himself in so particular a manner that David Loch, general inspector of the fisheries in Scotland, in de-

Rennie.

Rennie. scribing a visit which he paid to the school at Dunbar in 1778, notices the great proficiency displayed by young Rennie, prophesying that at no distant period he would prove an honour to his country. (*Loch's Essays on the Trade, Commerce, Manufactures, and Fisheries of Scotland*, vol. iii., p. 211.) From this school, in less than two years, he returned to Meikle, with a mind well stored with every branch of mathematical and physical science which Gibson could teach him. About this time, Gibson being appointed master to the public academy of Perth, he earnestly recommended young Rennie to succeed him at Dunbar. But his views were of a more aspiring cast. As a matter of favour, he undertook the management of the school for about six weeks, when he returned to his family, occasionally visiting and assisting his friend Meikle, but mostly improving himself in drawing and making models of machinery. His first essay in practical mechanics was the repairing of a corn-mill in his native village; and he erected two or three others before he was eighteen years of age.

Resolved, however, that these mechanical occupations should not interfere with his studies, he laid his plans so that he should be able to proceed occasionally to Edinburgh with a view of improving himself in physical science. He there attended the lectures of Professors Robison and Black, and formed that acquaintance with the former of those gentlemen which was gradually raised into friendship, and which perhaps may be said to have laid the foundation of his future fortune; for by him he was introduced to Messrs Bolton and Watt of Soho, near Birmingham. With these gentlemen he remained but a few months for the purpose of receiving explanations respecting the plan of the Albion Mills, then erecting, the machinery of which he superintended. This exactly suited his views; for, conscious of his own powers, he deemed the capital the proper theatre to try his strength, and in this he was not mistaken.

In proceeding from Edinburgh to Soho, he had taken the route by Carlisle, Lancaster, Liverpool, and Manchester, for the purpose of visiting the different mills and public works in those great commercial and manufacturing towns; and the remarks which he made on the bridge then building over the Lune at Lancaster, on the docks at Liverpool, and more particularly on the Bridgewater Canal, are distinguished by great sagacity, and were of essential use to him afterwards. On leaving Soho, he again made a tour through the manufacturing districts of Leeds, Sheffield, Rotherham, and Newcastle.

For some time after he was settled in London the Albion Mills, of which Bolton, Watt, and Wyatt were the projectors and leading proprietors, and who engaged him to superintend the execution of the mill-work, occupied a great share of his attention. Watt, in his *Notes to Professor Robison's Account of the Steam-Engine*, says, that "in the construction of the mill-work and machinery they derived most valuable assistance from that able mechanician and engineer Mr John Rennie, then just entering into business, who assisted in placing them, and under whose direction they were executed." He also says that the machinery, which used to be made of wood, was here made of cast-iron, in improved forms; and thinks that this was the commencement of that system of mill-work which has proved so beneficial to this country. In fact, Rennie's mills are the most perfect species of mechanism in that way that exist, distinguished by a precision of movement and a harmony and proportion of parts that now serve as models throughout the empire. His water-mills are so accurately calculated that every particle of water is effectively employed, and none of it lost, as in the common mode of constructing water-wheels. There is reason to believe that the difficulties which occurred at the Albion Mills with regard to the ebb and flow of the tides, and which

Rennie. required all the ingenuity of that extraordinary genius Watt, first led Rennie to the study of that branch of civil engineering connected with hydraulics and hydrodynamics, and in which he soon became so celebrated as to have no rival after the death of Smeaton, in whose steps, he always used to say, he was proud to follow.

Our limited space will not permit us to enter upon even an enumeration of all his great works, much less to give any detailed account of them; we must therefore content ourselves by mentioning some of the most important designs and undertakings in his threefold capacity of mechanist, architect, and civil engineer; three branches of art so intimately blended as scarcely to admit of a separation.

First, as a mechanist. Immediately after the completion of the Albion Mills, in 1786 or 1787, Rennie's reputation was so firmly established in everything connected with mill-work that he found himself in a very extensive line of business. To him the planters of Jamaica and of the other West India Islands applied for their sugar-mills, which he constructed in a manner so superior to the old ones that he soon obtained almost a monopoly of these expensive works. The powder-mill at Tunbridge, the great flour-mill at Wandsworth, several saw-mills, the machinery for various breweries and distilleries, were mostly of his manufacture; and wherever his machinery was required to be impelled by steam, the incomparable engines of his friends Messrs Bolton and Watt supplied the moving power; but, contrary to what has been stated in some of the public journals, he never had the least concern in directing, contriving, or advising any one part or movement of the steam-engine. He also constructed those beautiful specimens of machinery, the rolling and triturating mills, at the Mint on Tower Hill, to which Bolton and Watt's engines give motion; and at the time of his death he was engaged in the construction of a rolling-mill, and similar machinery, for the intended mint at Calcutta.

As a bold and ingenious piece of mechanism, which may be considered as distinct from positive architecture, there was nothing in Europe that could bear a comparison with the Southwark Bridge. The three immense arches, the centre one of 240, and each side arch of 210 feet span, consist entirely of masses of cast-iron, of various forms and dimensions, put together on the same principle as a similar fabric of hewn stone; a method of employing iron which may be considered to form a new epoch in the history of bridge-building. Various sinister predictions were entertained against this light and beautiful bridge, which was to be rent in pieces by the expansive power of the first summer's heat, or, if it escaped that, by the contraction of the first winter's cold; but it has stood the test of many winters and summers, and appears not to feel either. Rennie was applied to by the East India Company for the design of a cast-iron bridge to be thrown over the River Goomty at Lucknow, at the desire of the nabob vizier of Oude. It consisted of three arches of cast-iron, the centre arch 90, and each of the other arches 80 feet span. The arches were cast, and a superintending engineer sent out with them; but on their arrival, the nabob, in one of those moments of caprice to which eastern despots, even in their impotency, are so liable, changed his mind, and would not allow it to be put up.

Secondly, as an architect. Since there are few parts of civil engineering that do not occasionally require the aid of architecture, Rennie, at a very early age of his progress, was called upon for a display of his skill in this line. Amongst his first undertakings in either line was that of the Lancaster Canal, which presented many difficulties, and amongst others, that of carrying it by an aqueduct over the Lune, so as not to interrupt the navigation of the river. Being one of the largest fabrics of its kind in Europe, and of a pleasing design, it is an object that arrests the attention

Rennie. of strangers, and is very generally admired. The bridges of Leeds, Musselburgh, Kelso, Newton-Stewart, Boston, New Galloway, and a multitude of others, attest the architectural skill, the solidity, and, we may add, the good taste of Rennie; whilst a thousand smaller ones, with the various locks, wharf-walls, quays, embankments appertaining to canals, rivers, and harbours in every part of the United Kingdom, are so many proofs of his diversified talent, and his skill in adapting the means to the end. The breakwater in Plymouth Sound can scarcely be called an architectural work, but it is constructed on true hydrodynamical principles, and so gigantic in its dimensions, and cyclopean in its structure, as to defy equally the force of the waves and the ravages of time. To Whidby, who zealously superintended the execution of this immortal work, the highest praise is also due; nor was the plan finally determined on without his advice and assistance.

But the architectural work which, above all others, will immortalize the name of Rennie, is the Waterloo Bridge, a structure which, even according to foreigners, had no parallel in Europe (and if not in Europe, certainly not in the whole world) for its magnitude, its beauty, and its solidity. That a fabric so immense, presenting a straight horizontal line, stretching over nine large arches, should not have altered more than a few inches, not five in any one part, from that straight line, is an instance of firmness and solidity utterly unknown, and almost incredible; but all Rennie's works have been constructed for posterity. The bridge of Neuilly, which the French ranked as superior to that of Waterloo, actually sunk 28 inches. Rennie made nothing slight; nor would he engage in any undertaking where, from an ill-judging economy, a sufficiency of funds was not forthcoming to meet his views. Another work, executed from a design of his, is that of the stone bridge over the Thames, by which the old London Bridge, so long the disgrace of the metropolis, was replaced. His design, which was selected by a committee of the House of Commons, out of at least thirty that were offered, consisted of a granite bridge of five arches, the centre one of 150 feet span, being one of the largest stone arches in the world which has been constructed in modern times. Of the bridges which connect the banks of the Thames, three have been built from the designs of one man; a fact which must throw a lustre on the name of Rennie, and be regarded with a feeling of pride by the most distant connection of his family.

Thirdly, as a civil engineer. The first great attempt in this line of his profession was the survey and execution of the Crinan Canal, a work remarkable for the multitude of practical difficulties that occurred throughout the whole of this bold undertaking, it being necessary in many places to cut down through solid rock to the depth of 60 feet; and it is rather remarkable that the second undertaking, the Lancaster Canal, was also replete with difficulties, and called for the exercise of his skill as an architect, as we have already seen in noticing the aqueduct over the Lune. But these two works established his reputation as a civil engineer, and his opinion and assistance were required from all quarters. His faculties were now called into full play, and they expanded with the demands made upon them. The following are some of the most important of those the execution of which he personally attended:—Aberdeen, Brechin, Grand Western, Kennet and Avon, Portsmouth, Birmingham, Worcester, besides many others. But the resources of his mind were displayed in all their vigour in the plans and construction of those magnificent docks which are at once an ornament to the capital, and of the utmost utility to commerce and navigation. Nor are these splendid and useful works confined to the metropolis. The docks at Hull, Greenock, Leith, Liverpool, and Dublin attest his skill; and the harbours of

Queensferry, Berwick, Howth, Holyhead, Dunleary (now called Kingstown Harbour), Newhaven, and several others owe their security and convenience to his labours. But even these works, splendid as they are, must yield to what he has planned and executed in her Majesty's dockyards at Portsmouth, Plymouth, Chatham, and Sheerness. The last was a mere quicksand of 40 feet in depth, mixed with mud and the wrecks of old ships; the whole of which was excavated, and a magnificent basin constructed, with a beautiful surrounding wall of granite, with which three of the finest dry docks in the universe communicate; and that important dockyard, which may be said to command the mouths of the Thames and the Medway, from being an unhealthy and detestable place, and wholly inefficient for its purpose, is now, by being raised many feet, and laid out with skill and judgment, one of the most convenient in the kingdom. He also planned the new naval arsenal at Pembroke, which is considered as a perfect model for a building-yard. The repairing of the pier-head of Ramsgate harbour was a remarkable instance of his skill. The violence of the waves, acting upon the bad quality of the stone, had so completely undermined it that the stability of the whole pier began to be endangered. It was from 10 to 13 feet below the level of low-water, spring-tides; yet, by means of the improved diving-bell and its apparatus, the pier-head was not only effectually secured, but rendered more solid and durable than it originally had been. In the harbour of Howth the diving-bell was of the utmost use; and it is remarkable enough that the masons who have been for a little while accustomed to work under water prefer it—at least the Irish masons do—to working in the air, it being cooler in summer, and warmer in winter; though an increase of pay for submarine work is probably the real cause of preference.

The last effort of Rennie's genius to which we shall advert was the drainage of that vast tract of marsh land bordering upon the rivers Trent, Witham, New Welland, and Ouse which for centuries past had baffled the skill of some of the ablest men in that department of civil engineering. Upon the same principles, he laid down a grand scheme for draining the whole of that immense district known by the name of the Bedford Level, which has in part been carried into execution by the completion of the Eau-brink Cut, near Lynn. The estimate he made for draining the whole amounted to L.1,200,000.

Rennie's industry was very extraordinary; though fond of the society of his select friends, and of rational conversation, he never suffered amusement of any kind to interfere with his business, which seldom engaged him less than twelve hours, and frequently fifteen, in the day. His conversation was always amusing and instructive. He possessed a rich fund of anecdote, and, like his old friend James Watt, told a Scotch story admirably. As a travelling companion, he was highly entertaining; he knew everybody on the road, and everybody knew John Rennie. Of an ardent and anxious mind, and naturally impetuous, he was gifted with the most perfect self-control; and the irritation of the moment was seen but as a light summer's cloud passing across his finely-marked features, which were on so large a scale, though blended with much mildness as well as dignity, as to obtain for his noble bust by Chantrey, when exhibited in Somerset House, the name of *Jupiter Tonans*.

Rennie possessed considerable skill in bibliography; and being a zealous and liberal collector, he succeeded in forming a very valuable library, consisting of the best and rarest books in all the branches of science and art, of voyages and travels, and many curious books in the black letter; whilst in his own department it contained every work of the least merit, in whatever language it might be written. He had, besides, a good collection of mathematical and

Rennie.

astronomical instruments, and frequently spoke of erecting an observatory, but did not live to carry his intention into execution. He had for some years laboured under a disease of the liver, which had apparently yielded to the usual treatment; but a relapse took place, and on the 16th of October 1821, after a few days' illness, he expired without a struggle, in the sixtieth year of his age.

Rennie, in 1789, married Miss Mackintosh, who died in 1806, leaving a family of seven young children. His remains were accompanied to St Paul's by men of eminence in the arts, in science, and in literature, and were interred near those of Sir Christopher Wren. A plain granite slab covers his grave, on which is inscribed an appropriate epitaph.

J. B.—W.

RENT. See POLITICAL ECONOMY.

RENTON, a village of Scotland, in Dumbartonshire, near the right bank of the Leven, 2 miles N. of Dumbarton. It has an Established church, a Free church, and a Reformed Presbyterian church, several schools, and a library. There is here a monument to Smollett, who was born in the vicinity, and has described the Leven and adjacent country in his poetical and prose works. The people are to a large extent employed in dyeing and bleaching establishments. Pop. 2398.

RENWICK, JAMES, the last of the Scottish martyrs, was the only surviving child of a poor weaver, and was born in the parish of Glencairn, Dumfriesshire, in 1662. After he had entered the university of Edinburgh the Covenanted faith, in which he had been brought up, came boldly into action. He refused to take the oath of allegiance which was tendered to him at his laureation. At length he consecrated his life to the covenanting cause, by repairing to Holland at the request of the praying societies of Scotland, for the purpose of receiving ordination. Renwick returned to his native country in 1683, to enter into a perfect storm of persecution. Daring to take upon himself the task of preaching to the scattered Nonconformists in the south and west of Scotland, he provoked the savage malignity of many enemies. The government set a price upon his head, and declared him an outcast from society. Bands of dragoons were ready to hunt him down

wherever he appeared. Even some of the friends of the Covenant came to misrepresent his patriotic and religious zeal. He was reduced to the greatest shifts in the pursuit of his ministerial vocation. Often did he cower for bed and shelter in the holes of the ground. Often did he hold his meetings at the dead of night in the heart of the wilderness. At length he was caught one January morning on the Castlehill of Edinburgh; and in February 1688, on the scaffold in the Grassmarket, he met his death with the ecstatic welcome of a saint. (See Simpson's *Life of Renwick*.)

REPEATING CIRCLE. See BORDA.

REPP, THORLEIF GUDMUNDSSON, a learned author, was born as Reykiadal in Iceland in 1794, and received his education at the university of Copenhagen. He was known in Britain between 1825 and 1837 as a foreigner of great acquirements. The curators of the Advocates' Library had brought him over to Edinburgh to be their sub-librarian. His acquaintance with the modern languages and with Hebrew and Arabic was extensive. Nor was he incompetent to write English. In 1832 he published *A Historical Treatise on Trial by Jury, Wager of Law, and other co-ordinate Forensic Institutions formerly in use in Scandinavia and in Iceland*; in 1833 he wrote an article on the Advocates' Library for the *Penny Cyclopædia*; and about the same he contributed to the literature of the country several translations from the German and Italian. After his return to Copenhagen in 1837, Repp continued his literary labours. Among other works, he wrote a pamphlet in Danish, entitled *Dano-Hungarian Discoveries*, Copenhagen, 1843; and compiled, in conjunction with Ferrall, a *Danish and English Dictionary*, 12mo, Copenhagen, 1845. He died in 1858.

REPRIEVE, in criminal law (from Fr. *reprendre*, to take back), is the withdrawing of a sentence for an interval of time, by which means the execution is suspended. This may be either before or after judgment, as where the judge is not satisfied with the verdict, the evidence, or the indictment; or sometimes if any favourable circumstances appear in the character of the criminal, in order to give time to apply to the crown for either an absolute or conditional pardon.

REPTILIA: REPTILES.¹

THESE form the third great division of the animal kingdom, and in systematic works on natural history occupy an intermediate position between the class of birds and that of fishes.²

As in tracing the modifications of various organs, from the zoophitical and radiated animals to the molluscous, from these to the articulated classes, and onwards through the fishes to the reptile tribes, it is among the last named that we first perceive the passage from the truly aquatic to the terrestrial or air-breathing animal,—so the respiratory organs of such tribes are naturally those which excite the greatest and most peculiar interest. Among the more important classes of animals, respiration is effected in one or other of two ways; 1st, either by certain internal cellular sacs, for the reception of air, called *lungs*, which communicate with the mouth and nose by means of the trachea or windpipe; or, 2^{dly}, by external organs called *gills*, which require either to float in water, or to be in some other way continually immersed in that fluid. The object of both contrivances is to subject the blood to the influence of vital air, and this end is obtained very admirably, though

in a different way, by each. All mammiferous animals, including whales, all birds, and all reptiles (in the perfect state), possess the first form of the respiratory organs; all fishes, and several reptiles in their adolescent condition, are distinguished by the second. But even among such as are furnished with true lungs we observe different modifications of the circulating system.

The principal characteristic of reptiles in general consists in this, that only a portion of the blood is transmitted through the lungs, the remainder being projected by the heart directly to the other parts of the body, without being specially subjected to the influence of the respiratory organs; whereas, in the higher classes, such as man, the rest of the mammalia, and birds, the whole of the blood must pass by the lungs before it is retransmitted to the more distant parts of the circulating system. The amphibious habits of such reptiles as are unprovided with gills result in a great measure from the power which they thus possess of carrying on a partial circulation of the blood independent of respiration. The respiration of animals, or the process by which the blood is oxygenated, becomes weaker and less

¹ The natural history of reptiles is frequently treated of under the term *ERPETOLOGY*, from *ἑρπεν*, reptile, and *λογος*, discourse. The verb *ἑρπεν* signifies to creep.

² See ANIMAL KINGDOM.

Reptilia. frequent in proportion to the diminution which takes place in the quantity of blood transmitted to the lungs, compared with that which passes directly from the heart; and as it is respiration which warms the blood, and produces in the fibres their susceptibility of nervous irritation, it follows, as observed by Cuvier, that the blood of reptiles is cold, and their muscular strength much less than that of birds and quadrupeds. The seat of their sensations is also much less centralised than in the last-named classes, and hence many of them exhibit life and motion long after their heads have been severed from their bodies.¹

A truly amphibious animal, according to the proper meaning of the term (which is derived from *ἀμφι*, on both sides, and *βίος*, life), ought to possess the power of breathing under water like a fish, and of respiring atmospheric air like a land animal. According to this interpretation, neither seals, nor beavers, nor even whales, are truly amphibious, for they cannot sustain their existence under water except by the use of a certain portion of air which they have previously inspired at the surface. In like manner, neither the frog nor the tadpole is amphibious (unless it may be for a short intermediate period, or state of transition); for the former seeks the water merely as a place of temporary resort, in which it cannot breathe, and the latter is entirely aquatic, being unprovided with lungs, and consequently unable to respire, except through the medium of water. A frog, therefore, can only be said to be amphibious in as far as it possesses, at two different periods of its life, the faculty of living first in the water and then on the land. Born with gills, and destitute of external members, its form and functions are originally rather those of a fish than of a reptile; but as it advances in growth, the four limbs become developed, the tail decreases and disappears, the jaws are formed, and the gills absorbed, and their functions supplied by lungs. But the peculiar structure of the heart, already mentioned, enables these and other species to remain submerged for a great length of time.

Among the many wonderful anomalies, however, with which the kingdom of nature presents us, there exist two truly amphibious animals, the *proteus* and the *siren*, both of which are provided at one and the same time with the gills of a fish and the lungs of a terrestrial creature. But their propensities are decidedly aquatic. The former inhabits certain subterranean waters in Carniola, the latter rejoices in the muddy marshes of South Carolina.² Both will be hereafter noticed.

The amount of respiration is by no means so fixed or determinate among reptiles as it may be said to be in quadrupeds and birds, but varies with the proportion which the diameter of the pulmonary artery bears to that of the aorta. Thus, turtles and lizards respire much more than frogs and others of the class; and from this results a much greater difference in energy and sensibility between different tribes of Reptilia, than exists among the members of the class of quadrupeds or birds. Reptiles also may be said to exhibit a much greater variety of form, aspect, and condition, than either of the classes just named; and it is in their production that nature (as we are wont to term the powers of the Omnipotent Creator), has invented the most extraordinary forms and modifications which exist among the vertebrated division of the animal kingdom.

No reptile is known to hatch its eggs, and in the Batrachian order (frogs, toads, &c.) fecundation does not take

place till after the female has excluded the so-called ova, which in such cases are covered merely by a slight and simple membrane, bearing no resemblance to a shell. The young of this Batrachian order, on leaving the egg, bear the general form of fishes, and are, moreover, furnished with gills, which a few of them retain even after acquiring lungs, and assuming the other attributes of maturity. Among several of the egg-laying species, the included young are not only formed, but far advanced at the period of laying; while a few, such as vipers and certain lizards, are actually born alive, being hatched within the body of the mother. Hence the expression by which these are designated, of *ovo-viviparous*. Some even of those which usually lay eggs may be rendered viviparous by a short retardation of the process of laying, as effected by M. Geoffroy in the case of certain snakes by merely depriving them of water.

Although many reptiles are active leapers, and even run with rapidity for a short distance, the coldness of their blood, and proportional want of muscular power, induce on the whole an indolent habit. They are probably, of all vertebrated animals, the least perfectly endowed with the power of migratory movement. The brain is proportionally very small, a sea-tortoise, for example, weighing twenty-nine pounds, having been found to possess brains to the weight only of two drams, that is, equal to not more than an eighteen hundred and fifty-sixth part of the entire animal. Now, we know, that in several small birds and quadrupeds, the brain exceeds a thirtieth part of the remainder of the body. In reptiles, indeed, the brain seems less necessary than among other vertebrated beings, to the exercise of the animal and vital functions, and their sensations are less referable to a common centre. Connection with the nervous system is also much less necessary to the contraction of their fibres, and a portion of their flesh possesses its irritability long after separation from the rest of the body. The heart beats for several hours after being extracted, and the said extraction does not prevent the body itself from moving about for a considerable time. The cerebellum in several species is extremely small, a fact regarded as being in exact accordance with their indolence of movement.

The small size of the pulmonary vessels admits of reptiles suspending their respiration without arresting the course of the blood, and they can accordingly dive more easily, and continue submerged for a longer time, than either mammiferous quadrupeds or birds. The cellules of the lungs being less numerous, as having fewer vessels to lodge upon their parietes, are much wider, and these organs have sometimes indeed the form of simple sacs scarcely cellular.

They are all provided with a trachea and larynx, although many are entirely mute. Their blood being naturally cold, they have no need of such integuments as fur or feathers to retain the heat, and are covered either by scales or a naked skin.

Although no portion of the organ of hearing is external in reptiles, yet among crocodiles there is an appearance of an outer *meatus auditorius*, owing to the skin forming a thick cover over the tympanum. This peculiar formation is sufficient to explain a passage in Herodotus, who states, that the Egyptians were in the habit of suspending jewels from the ears of the crocodile.

The digestion in reptiles is extremely slow, and all their sensations are obtuse. In cold, and even in temperate climates, they fall into a state of torpor during the prevalence

Reptilia.

¹ "Les muscles des reptiles conservent plus long temps encore leur irritabilité que ceux des poissons. Nous avons vu des crapauds, des salamandres, des tortues, des serpens, privés de la tête et dépouillés de leur peau depuis plusieurs jours, et maintenus humides, produire encore des mouvemens pendant des semaines entières; un tortue terrestre, du poids des près de 40 kilogrammes, morte depuis plusieurs jours, dont le cou était tombé dans cette sorte de flaccidité, suite de la raideur qui survient après la mort, dont les yeux en particulier avaient la cornée desséchée, manifester des mouvemens par la contractions et la retraction des membres, toutes les fois qu'on stimulait, en les piquant, les muscles des membres postérieurs." (Dumeril et Bibron, *Eryptologie*, i. 41.)

² See Wilson's *Illustrations of Zoology*, vol. i.

Reptilia. of chilly weather, being more than any other class of creatures under the influence of temperature,—“*frigida æstuantium animalia* ;” and what is truly singular, is the fact mentioned by Humboldt, that the inverse cause produces a corresponding effect on some of the species of tropical climates, the caymans or crocodiles of South America becoming torpid, and entombing themselves in mud, during the prevalence of the hottest season.

Indeed, among the more singular features in the economy of the reptile race, may be numbered their power of enduring long-continued abstinence, and the lethargic state, infinitely more profound than the winter sleep of quadrupeds, into which they yearly fall. In connection with this subject, Mr Jacobson of Copenhagen has recognised in reptiles a special arrangement of certain vessels which constitute a peculiar *venous system*. This system may be said to exist more or less in all the race ; but, rudimentary in the tortoises and crocodiles, it shows its chief development among the other Saurians, and the Ophidian and Batrachian groups. “ It is composed of the veins of the abdominal members, the pelvic or caudal veins, the hinder veins of the kidneys, the veins of the oviductus, a great portion of the veins of the skin, of those of the muscles of the abdomen, and of those of certain organs peculiar to the reptiles. These veins combine, and form one or many trunks, which proceed either into the vena porta or the liver, or into both. What especially distinguishes this system is, that in it a part of the veins of the organs of locomotion, and of the skin, proceed to distribute themselves into the liver. There is no other example of this among the vertebrated animals. Certain special organs appear connected with this venous system in a peculiar manner, and are regarded by Mr Jacobson as proper for secreting and preserving a nutritive juice, destined to be re-absorbed in the rigorous months of the severe season, during the hybernal slumber of these animals.”¹

In regard to the geographical distribution of reptiles in general, we shall here briefly observe, that they augment in number as we advance towards the equatorial regions. While Sweden possesses scarcely a dozen snakes and lizards, about three or four frogs and toads, and not a single tortoise, the temperate parts of Europe produce about forty snakes and lizards, and several of the tortoise tribe. In Scandinavia, however, although the species are so few in number, the individuals are much more abundant than in Britain ; from which we infer, that it is rather the want of strong continuous summer heat than the actuality of our winter’s cold, that is unfavourable to the production of reptiles in our cloudy clime. As soon as we gain the southern extremity of Spain, the number of species in these tribes greatly increases, and in Andalusia the African complexion of the country is still further manifested by the frequent appearance of the chameleon. On proceeding further south, not only does the number of reptiles increase, but they also augment in size, splendour, and ferocity, till from the Tropic of Cancer onwards and beyond the line, we meet with crocodiles, caymans, boas, and other giants of the reptile race. Several species, however, even in sultry latitudes, are subjected by their peculiar position to the influence of severe cold. Thus the *axolotl* of Mexico occurs in the chill waters of lakes elevated above 8000 feet from the surface of the sea ; and the salamander (a water newt) of Europe is frequently found frozen up in ice in early spring, without being destroyed. Indeed, Dufay has remarked, as a singular circumstance, that those very animals of which it once was fabled they could withstand the fiery flames, are in reality endowed with the almost equally surprising power of resisting frost, so generally fatal to the life of reptiles.

Reptilia. Although we have now endeavoured to state a few of what may be regarded as the generalities of the reptile class, yet it must be borne in mind, that no great division of the animal kingdom exhibits such a singular diversity of form and aspect, or is more liable to exceptions from whatever features we may incline to consider as general characteristics. “ *Aussi les reptiles,*” says Baron Cuvier, “ *présentent-ils des formes, des mouvements, et des propriétés beaucoup plus variées que les deux classes précédentes (quadrupeds and birds) ; et c’est surtout dans leur production que la nature semble s’être jouée à imaginer des formes bizarres, et à modifier dans tous les sens possibles le plan général qu’elle a suivi pour les animaux vertébrés, et spécialement pour les classes ovipares.*” Among no animals indeed do we meet with beings of more singular forms than in the class Reptilia, many of which exhibit an aspect so unusual, so grotesque, and even so formidable, that it would be difficult for the imagination of the poet or the painter to exceed the “dread realities” of nature. Although the majority are oviparous, some, as we have said, produce their young alive. Many have four legs, some only two, which vary from an anterior to a posterior pair, while the entire tribe of serpents have no legs at all. Some have their bodies more or less closely beset by scales, varying in size from extreme tenacity to the strength and thickness of mailed armour ; many, as the numerous tribes of frogs, are defended only by a soft and mucous skin ; as many more are shut up in a strong bony box-like covering, within which they dwell, as in an impregnable castle. The greater number possess a tail, but several entirely want that organ. Numerous tribes live unceasingly in the water, others pass their infancy in moist abodes, their maturer years on terra firma, provided in the former case with gills, in the latter with lungs for respiration. Marshes and muddy swamps, the dry and desert sands, the umbrageous woods, the upland mountains, the “resounding shores,” are all alike pervaded by one or many of the numerous forms of reptile life. The subterranean proteus fears the light, though dealing in no deeds of darkness ; the agile lizard, “all scaled silver bright,” basks delighted beneath the beams of the most brilliant sun, “no cloud in heaven.” Some are fierce and carnivorous, others gentle and herbivorous. The most deadly poison is distilled by many, while entire tribes are quite innocuous ; and while some are resplendent in burnished gold and azure, “like mailed angels on a battle-day,” as many exhibit the last stage of ugliness in

worse
Than fables yet have feigned or fear conceived,
Gorgons, and hydras, and chimeras dire.

It has been observed, that in the popular superstitions of various countries, the reptile race have been almost always clothed in revolting attributes, and that the worship accorded them was one not of gratitude, but fear.² Victor or vanquished, they seem ever to have borne a cruel and pestilential character, in opposition to the welfare of the human race ; and the prowess both of gods and men was called into frequent and vigorous exercise for their subduction. “Glorious Apollo” pursued the enormous Python with his unerring shafts ; the dreadful Achelous was strangled by the son of Jove, in spite of folds “voluminous and vast ;” the Hesperian gardens and the golden fleece were protected by fierce dragons ; Perseus, from the dripping head of Medusa, sowed with serpents the arid Libyan sands ; and gorgons and furies, discord and envy, are armed by the poets with snakes, “as appropriate emblems of their ministry of vengeance.”

It was chiefly on the comparative consideration of the amount of respiration, and of the organs of movement, that

Chelonia. M. Brogniart founded the four great orders of the class Reptilia, which are now so generally adopted in the works of systematic authors.¹ They are as follows.

1st, The CHELONIAN REPTILES (turtles, tortoises, &c.), of which the heart is provided with two auricles, and the body, borne on four legs, is contained as it were within an upper and an under buckler, formed by a peculiar structure of the ribs and sternum.

2d, The SAURIAN REPTILES (crocodiles, lizards, &c.), which have likewise two auricles and four legs, but the body is covered with scales.

3d, The OPHIDIAN REPTILES (or serpents), which have a heart furnished with two auricles, but the body is destitute of legs.

4th, The BATRACHIAN REPTILES (frogs, toads, &c.), in which the heart has only a single auricle, the body is naked, and the majority of species undergo a kind of transition as they advance in age, from the form of a fish with gills to that of a quadruped with lungs. Some, however, as already mentioned, never lose their gills, and a few have only a single pair of legs.

Our notices of the various genera of the different orders must be here extremely brief; and in the following slight sketch we shall adhere, as we have done in most of our zoological treatises, to the systematic exposition of Baron Cuvier.²

ORDER I.—CHELONIA. CHELONIAN REPTILES.

The various groups of this order are known to English readers by the general names of *tortoise* and *turtle*,—the former appellation being usually bestowed on those which dwell on land, the latter on such as inhabit water. The heart is composed of two auricles, and of a ventricle with two unequal chambers communicating with each other. The blood from the body enters into the right auricle, that from the lung into the left; but both streams mingle together more or less in passing by the ventricle.

All the species of this order are distinguished at first sight by the peculiar armature in which the body is contained, and which consists of an upper and under buckler, nearly meeting along their edges, and permitting only the

head, limbs, and tail to appear externally. The upper buckler, called the *carapace*, is formed by the ribs, which amount to eight pair, extended and united by toothed sutures between, and having bony plates adhering to the annular portion of the dorsal vertebræ, and so connected that all these parts are rendered motionless. The under buckler is called the *plastron*, and is composed of portions which represent the sternum, and which are usually nine in number. A kind of lateral edging or frame-work, consisting of osseous pieces, bearing some analogy to the sternal or cartilaginous portion of the ribs, and which in one sub-genus even continue cartilaginous, surrounds the carapace, binding and uniting together the ribs by which it is composed. Thus the cervical and caudal vertebræ alone retain the power of distinct movement. (See Plate I., fig. 1.)

These two bony envelopes being covered immediately by skin or scales, the shoulder-blade and all the muscles of the neck and fore-arms, instead of having their attachments over the ribs and spine, as in other animals, are supported from beneath these parts; and the same peculiarity occurs in relation to the bones of the lower extremity and the muscles of the thighs, so that, as Baron Cuvier observes, a turtle may be termed "*un animal retourné*," as if it had been turned inside out.

The vertebral extremity of the shoulder-blade articulates with the carapace; and the opposite end, which may be regarded as analogous to the clavicle, articulates with the plastron in such a manner that the two shoulders form a ring through which the œsophagus and wind-pipe pass. A third bony branch, larger than the other two, and directed downwards and backwards, represents, as in birds, the coracoid process, but its posterior extremity is free.

The lungs are much expanded, and lie in the same cavity with the other viscera. The thorax being immovable in the majority of species, it is by the play of the mouth that the Chelonians respire,—holding the jaws closed, and alternately lowering and raising the hyoid bone. The first movement permits the air to enter by the nostrils, and then the tongue closing the interior opening, the second movement forces the air into the lungs.

The Chelonians have no teeth, but their jaws are furnished with a horny substance like the mandibles of birds, with the exception of the *Chelydes*, in which they are covered

¹ *Essai d'une Classification Naturelle des Reptiles*, Paris, 1805.

² The following are some of the principal works on reptiles in general. We do not here name those systematic writers who have treated of the class in question merely in the course of their universal exposition of the animal kingdom, although they are elsewhere referred to in the progress of the present treatise.

J. N. Laurenti, *Specimen Medicum, exhibens synopsis Reptilium emendatam, cum experimentis circa venena et antidota Reptilium Austriacorum*, 1768. This work has been since attributed to M. Winteil, a chemist of Vienna, who is merely named by Laurenti, on the terminal page, as having been a co-labourer in his therapeutical experiments. Lacepède, *Histoire Naturelle des Quadrupèdes Ovipares et des Serpens*, 2 vols. 4to, 1788-90. The Abbé Bonnaterre is the author of the text which accompanies the plates of reptiles in the French *Encyclopédie*, under the title of *Tableau Encyclopédique et Méthodique des trois Règnes de la Nature (Erpétologie et Ophiologie)*, 4to, 1789-90. L. J. M. Daubenton composed *Les Quadrupèdes Ovipares et les Serpens*, in *Dictionnaire des Animaux Vertébrés*, tom. ii. part. de l'Encyclop. Méthod. J. G. Schneider, the celebrated Greek scholar, has not published any general work on reptiles, but has written extensively on various groups. His productions are the following:—*Amphibiorum Physiologia Specim. i. and ii.* 1797. *Amphibiorum naturalis et litterariæ Fasciculus primus, continens Ranas, Salamandras, Bufones, Salamandras, et Hydros, in genera et species descriptas notisque suis distinctos*, 1799. *Fasciculus secundus, continens Crocodilos, Scincos, Chamæsauros, Boas, Pseudoboas, Elapes, Angues, Amphisaurus, Cæculius*, 1801. Latreille, *Histoire Naturelle des Reptiles*, four vols. small 12mo, 1801. Dr Shaw, *General Zoology*, vol. iii.—*Amphibia*, 1802. F. M. Daudin, *Histoire Naturelle des Reptiles*, eight vols. 8vo, 1802-3. Alex. Brogniart, *Essai d'une Classification Naturelle des Reptiles*, 1805. M. Oepel, *Die Ordnungen Familien und Gattungen der Reptilien, als Prodrum einer Naturgeschichte derselben*, one vol. 4to, 1811. Blas Merrem, *Tentamen Systematis Amphibiorum*, one vol. 8vo, 1820. A. H. Haworth, A Letter on the Binary Arrangement of the Class of Reptiles, in the *Philosophical Magazine* for 1825, p. 372. F. J. Fitzinger, *Neue Classification der Reptilien*, one small vol. 4to, 1826. Ritgen, A Classification of Reptiles, in *Nova Acta Acad. Nat. Cur.* for 1828. Bory St Vincent, *Résumé d'Erpétologie*, ou *Hist. Nat. des Reptiles*, 12mo, 1828. J. Wagler, *Natürliches system der Amphibien*, one vol. 8vo, 1830. We have also by the same author *Icones et Descriptiones Amphibiorum*, two fascic. folio, 1830, as well as some explanations and critical remarks on Seba's plates of reptiles (*Isis*, 1833, ninth cahier, p. 885). J. E. Gray, *Synopsis Reptilium*, part 1st, 1831; and later in the same year, *Synopsis of the Species of the Class Reptilia*, in Griffith's *Animal Kingdom*, end of vol. ix. John Müller, *Beiträge zur Anatomie und Naturgeschichte der Amphibien*, in *Zeitschrift für Physiologie von Tiedemann, &c.*, No. 19, p. 190, 1832. H. T. Schinz, *Naturgeschichte und Abbildungen der Reptilien*, 4 fascic. large 4to, 1833. We conclude the list with a reference to a work already named, and frequently hereafter quoted, the *Erpétologie Générale, ou Histoire Naturelle complète des Reptiles*, of Messrs Dumeril and Bibron. The best and latest work on one class of REPTILIA, the *Serpents*, is *Essai sur la Physionomie des Serpens* of M. Schlegel, superintendent of the Museum of Natural History at Leyden, published in two 8vo volumes and a folio volume of plates, at the Hague in 1837. A partial translation of it, by Professor Traill, appeared at Edinburgh, 1843.

Chelonia. ed with skin. Their tympanic cavity and palatine arches are fixed to the cranium, and immoveable. The tongue is short, and beset with fleshy filaments. The stomach is simple and strong, the intestines of medium length, and unfurnished with a cæcum. The bladder is very large. The females in this order produce eggs provided with a hard shell. The males of many species may be recognised by the greater concavity of the plastron.¹

The limbs of *Chelonian* reptiles being so confined between the carapace and plastron, their powers of locomotion, at least on land, are very limited. They can scarcely raise their bodies above the surface of the ground, and they advance by a slow, awkward, and apparently embarrassed action. But the aquatic species being provided with fin-like members, and dwelling amid a fluid well adapted to their use, the flat and smoothly expanded bodies of these creatures glide along with great ease and considerable swiftness. Such of the land species as inhabit temperate countries pass the colder seasons of the year in a state of torpidity, having previously excavated or taken possession of some secure and subterranean retreat. They are supposed to be extremely long lived. The marine species are more tropical in their distribution; and we are not aware that any hibernation takes place among them. They are often met with many hundred leagues from land. They deposit their eggs on sandy shores, where they are hatched by the heat of the sun,—the process of laying being usually carried on during the night.

The dimensions of animals of this order exhibit a great range, some being only a few inches in length, while others attain to a gigantic size, and weigh many hundred pounds. They are all extremely tenacious of life,—whether under the effects of long-continued abstinence while being conveyed from distant regions, or when suffering from the infliction of grievous wounds. Indeed they will live for months, or, as it is alleged, even for years, without any food, and will show decided symptoms of life and locomotion for several weeks after their heads have been severed from their bodies.

The whole of this order was formerly contained in the old and unrestricted genus *TESTUDO* of Linnæus, divided by Cuvier into the five following generic groups, of which the distinctive characters are mainly derived from the form and covering of the carapace, and from the feet.

GENUS *TESTUDO*, Brogn. Tortoises. Carapace bulged, supported by a solid bony frame-work, and soldered by the greater portion of its lateral edges to the plastron. Legs as if truncated, the toes extremely short, and united almost to the nails, of which there are five to the fore-feet, and four to the hinder, all thick and conical.

The species, most of which subsist on vegetables, are too numerous to be here described, but we shall indicate a few of the more noted or remarkable.

The Greek tortoise (*T. Græca*, Linn.) is the most common of the European kinds, and occurs in most of the countries which surround the Mediterranean, and in several islands of that sea. It is distinguished by its broad and equally bulged carapace, its relieved scales, granulated in the centre, striated on the margins, and spotted, or rather marbled, with black and yellow; in the centre of its posterior margin there is a small prominence slightly curved over the tail. The Greek tortoise lives on leaves, fruits, and insects. It sleeps throughout the winter, pairs in spring, and lays four or five eggs resembling those of a pigeon. It seldom attains to the length of twelve inches, its general extent being from six to eight. This species has been known to reach an extraordinary old age. One of the most remarkable instances has been often recorded. It

is that of a tortoise which was introduced into the archiepiscopal garden at Lambeth in the time of Archbishop Laud, about the year 1633, and continued there till 1753, when it died, as was supposed, rather from accidental neglect than the effect of old age. Its shell is preserved in the library of the palace. The Greek turtle is used as an article of food in some of the southern countries of Europe. According to Forskal, it retires under ground in September, and re-appears in February. In this country it hibernates later, and does not emerge so soon. It lays its eggs in June, in a small hole, which it scratches in some sunny spot, and the young are hatched in autumn, being on their first exclusion about the size of walnuts.

Of the foreign species, one of the most remarkable for size is the Indian tortoise (*T. Indica*, Vosm.), first described by M. Perrault. It has been taken on the coast of Comorand, and sometimes measures four feet and a half from the nose to the tail, with a height or convexity of fourteen inches. The shell is brown, reflected or turned upwards over the neck; and there is a tubercle on each of the three anterior scutella.

Other species are less remarkable for size than for the beautiful distribution of the colours by which they are adorned. Such is the geometrical tortoise (*T. geometrica*, Linn.), which is easily distinguished by the symmetrical regularity with which the yellow rays, and the alternate lines of brown and yellow, are disposed upon the scales of the upper shield. Certain species have the anterior part of the shield moveable, while in others the posterior portion is in that condition. The former constitute the genus *Pyxis* of Mr Bell, while the latter pertain to the genus *Kinixis* of that author.

GENUS *EMYS*, Brogn. Fresh-water tortoises.

The species of this genus are not distinguishable from those of the preceding by more important characters than the greater separation of the toes, which are terminated by longer nails, and have their intermediate spaces filled up by membrane. The number of the nails is the same, but the form of their feet enables them to indulge in more aquatic propensities. Their envelope is generally of a flatter form than that of the terrestrial species, and the majority live on insects, small fishes, &c. (See Plate I., fig. 2.)

One of the best known of this group is the speckled tortoise (*T. Europæa*, Schn.; *T. orbicularis*, Linn.), a small species, pretty widely distributed over the southern and eastern countries of Europe. Its carapace is of an oval form, but slightly convex, rather smooth, of a blackish colour, beset with innumerable small yellow spots. Its length seldom exceeds ten inches. This creature inhabits lakes, marshes, and muddy places. Its flesh is esteemed as food, on which account it is sometimes kept in ponds appropriated to the purpose, and fattened with lettuce leaves, bread, and other substances. It may also be kept in a cellar, and fed with oats scattered on the floor. These it eats readily, especially when they have begun to germinate. Its natural food, however, is said to consist of insects, slugs, &c. It deposits its eggs in warm and sandy places, and Marsigli alleges that an entire year elapses before they are hatched.

Another species of this genus is *la Bourbeuse* of the French (*T. lutaria*, Linn.), commonly called the mud-tortoise. It is a small animal, with a flattish brown-coloured shield, and a tail of considerable length, which, instead of being kept bent inwards, is stretched out in walking. It is well known in France, and is particularly plentiful in Languedoc and many parts of Provence. It has been known to occur in such abundance in a lake of about half a league in width in the plain of Durance, that the neighbouring peasantry, on one occasion, almost entirely sustained themselves

¹ Règne Animal, ii. 8.

Chelonia. upon them continuously for three months. Though the species is aquatic, it always lays its eggs on land. When the young are first hatched they do not measure above six lines in diameter. Like most other tortoises, it may be tamed, and its love of slugs and snails makes it a useful adjunct to a garden. Yet it must be borne in mind, that however beneficial to the horticulturist, it is a dangerous inmate of the fish-pond, where it attacks and destroys the inhabitants, first biting them till they become enfeebled through loss of blood, and then dragging them to the bottom, where it quietly devours everything but the bones and some of the cartilaginous parts of the head. The air-bladder also is often left, and, swimming on the surface, gives notice of the depredation done below. The mud-tortoise walks with greater quickness and activity than the ordinary land species, especially on even ground.

The painted tortoise (*T. picta*) likewise pertains to this genus. It is a beautiful little creature, with a smooth, rather flattish shield, of a brown colour, and each compartment bordered by a yellow band. It is a North American species, often seen congregated in clear sunny weather along the sides of rivers on stones and trunks of fallen trees, from which it plunges into the water on the slightest disturbance. It swims swiftly, but walks slowly, and is said to be very voracious, sometimes even destroying ducklings, by seizing their feet and dragging them below the water.

A few species with the neck more elongated (such as *T. longicollis*, Shaw) form the genus *HYDRASPIS* of Bell. There are also some peculiar species called *tortues à botte* by the French, in which the plastron or lower shield is divided into two by a moveable articulation. These tortoises can close their carapace, and so shut themselves up as in a box, after having drawn in their head and legs. Such is the close tortoise (*T. clausa*, Gmel.), so called on account of the peculiarity just alluded to. The shell is of great strength, and although the creature itself rarely exceeds a few inches in length, it remains uninjured under a weight of five or six hundred pounds. It occurs in different parts of North America, being usually found in marshy places, though sometimes seen in dry and sultry situations. It feeds on insects, mice, and even snakes, which it is said to seize by the middle, and crush to death by drawing them within its shell.

Others have the tail and limbs by much too large to be withdrawn into the shell. Such is the long-tailed tortoise (*T. serpentina*, Linn.), a fresh-water species, native to the warmer parts of North America, where it is known under the name of snapping turtle. It is of considerable size, sometimes weighing twenty pounds, and seizes upon its prey (fish, ducklings, &c.) with great force and rapidity, stretching out its neck, and uttering a hissing sound. Its grasp is so tenacious that it will suffer itself to be lifted up by a stick rather than quit its hold. The tail is almost as long as the body, and is beset by sharp raised ridges. The plates of the shield assume a somewhat pyramidal form. (See Plate I., fig. 3.)

GENUS CHELONIA, Brogn. Turtles, or sea-tortoises. This group differs from all the preceding in its long, flat, fin-like feet, with the toes closely united, and enclosed within the membrane. The first two toes of each foot alone are furnished with nails, one or other of which often drops off at a certain term of life. The different portions of the lower shield do not form a continuous plate, but are variously dentated, and have large intervals covered by cartilage alone. The ribs are narrow, and separate from each other at their outer portion; but the circumference of the shield is occupied throughout by a circle of pieces corresponding to the sternal ribs. The interior of the œsophagus is entirely beset by sharp cartilaginous points directed towards the stomach.

To illustrate the prevailing habits of these curious creatures, we shall extract the following notices regarding se-

veral species of sea-turtle, from one of those delightful papers with which Mr Audubon has enlivened his Ornithological Biography. That gentleman's observations were made chiefly among the Tortugas, a group of low uninhabitable islands, or rather banks of shelly sand, which lie about eighty miles from Key West, off the peninsula of the Floridas. As usual, the author intermingles his minuter notices of natural history with very pleasing sketches of the general features of the surrounding scene. "If you have never seen the sun setting in those latitudes, I would recommend you to make a voyage for the purpose; for I much doubt if, in any other portion of the world, the departure of the orb of day is accompanied by such gorgeous appearances. Look at the great red disk increased to triple its ordinary dimensions! Now it has partially sunk beneath the distant line of waters, and with its still remaining half irradiates the whole heavens with a flood of golden light, purpling the far-off clouds that hover over the western horizon. A blaze of refulgent glory streams through the portals of the west, and the masses of vapour assume the semblance of mountains of molten gold. But the sun has now disappeared, and from the east slowly advances the gray curtain which night draws over the world." "Slowly advancing landward, their heads alone above water, are observed the heavily-laden turtles, anxious to deposit their eggs in the well-known sands. On the surface of the gently rippling stream, I dimly see their broad forms, as they toil along, while at intervals may be heard their hurried breathings, indicative of suspicion and fear. The moon, with her silvery light, now illumines the scene, and the turtle having landed, slowly and laboriously drags her heavy body over the sand, her 'flappers' being better adapted for motion in the water than on shore. Up the slope, however, she works her way, and see how industriously she removes the sand beneath her, casting it out on either side. Layer after layer she deposits her eggs, arranging them in the most careful manner, and, with her hind paddles, brings the sand over them. The business is accomplished, the spot is covered over, and with a joyful heart the turtle swiftly retires towards the shore, and launches into the deep." "There are four different species, which are known by the names of the *green turtle*, the *hawk-bill turtle*, the *loggerhead-turtle*, and the *trunk-turtle*. The first is considered best as an article of food, in which capacity it is well known to most epicures. It approaches the shores, and enters the bays, inlets, and rivers, early in the month of April, after having spent the winter in the deep waters. It deposits its eggs in convenient places in two different times in May, and once again in June. The first deposit is the largest, and the last the least, the total quantity being at an average about two hundred and forty. The hawk-bill turtle, whose shell is so valuable as an article of commerce, being used for various purposes in the arts, is the next with respect to the quality of its flesh. It resorts to the outer keys only, where it deposits its eggs in two sets, first in July, and again in August, although it 'crawls' the beaches of these keys much earlier in the season, as if to look for a safe place. The average number of its eggs is about three hundred. The loggerhead visits the Tortugas in April, and lays from that period until late in June three sets of eggs, each set averaging a hundred and seventy. The trunk-turtle, which is sometimes of an enormous size, and which has a pouch like a pelican, reaches the shores latest. The shell and flesh are so soft, that one may push his finger into them, almost as into a lump of butter. This species, therefore, is considered as the least valuable, and indeed is seldom eaten, unless by the Indians, who, ever alert when the turtle season commences, first carry off the eggs, and afterwards catch the turtles themselves. The average number of eggs which it lays in the season, in two sets, may be three hundred and fifty."

Chelonia.

Chelonia.

"The loggerhead and the trunk turtles are the least cautious in choosing the places in which to deposit their eggs, whereas the two other species select the wildest and most secluded spots. The green turtle resorts either to the shores of the Maine, between Cape Sable and Cape Florida, or enters Indian, Halifax, and other large rivers or inlets, from which it makes its retreat as speedily as possible, and betakes itself to the open sea. Great numbers, however, are killed by the turtlers and Indians, as well as by various species of carnivorous animals, as cougars, lynxes, bears, and wolves. The hawk-bill, which is still more wary, and is always the most difficult to surprise, keeps to the sea-islands. All the species employ nearly the same method in depositing their eggs in the sand; and as I have several times observed them in the act, I am enabled to present you with a circumstantial account of it. On first nearing the shores, and mostly on fine calm moonlight nights, the turtle raises her head above the water, being still distant thirty or forty yards from the beach, looks around her, and attentively examines the objects on shore. Should she observe nothing likely to disturb her intended operations, she emits a loud hissing sound, by which such of her many enemies as are unaccustomed to it are startled, and so are apt to remove to another place, although unseen by her. Should she hear any noise, or perceive indications of danger, she instantly sinks and goes off to a considerable distance; but should everything be quiet, she advances slowly towards the beach, crawls over it, her head raised to the full stretch of her neck, and when she has reached a place fitted for her purpose, she gazes all around in silence. Finding 'all well,' she proceeds to form a hole in the sand, which she effects by removing it from *under* her body with her *hind* flappers, scooping out with so much dexterity that the sides seldom if ever fall in. The sand is raised alternately with each flapper, as with a large ladle, until it has accumulated behind her, when, supporting herself with her head and fore part on the ground fronting her body, she with a spring from each flapper sends the sand around her, scattering it to the distance of several feet. In this manner the hole is dug to the depth of eighteen inches, or sometimes more than two feet. This labour I have seen performed in the short period of nine minutes. The eggs are then dropped one by one, and disposed in regular layers to the number of a hundred and fifty, or sometimes nearly two hundred. The whole time spent in this part of the operation may be about twenty minutes. She now scrapes the loose sand back over the eggs, and so levels and smooths the surface, that few persons, on seeing the spot, could imagine anything had been done to it. This accomplished to her mind, she retreats to the water with all possible despatch, leaving the hatching of the eggs to the heat of the sand. When a turtle, a loggerhead, for example, is in the act of dropping her eggs, she will not move although one should go up to her, or even seat himself on her back, for it seems that at this moment she finds it necessary to proceed at all events, as she is unable to intermit her labour. The moment it is finished, however, off she starts; nor would it then be possible for one, unless he were as strong as a Hercules, to turn her over and secure her." "Persons who search for turtles' eggs are provided with a light stiff cane, or a gun-rod, with which they go along the shores, probing the sand near the tracks of these animals, which, however, cannot always be seen, on account of the winds and heavy rains that often obliterate them. The nests are discovered not only by men, but also by beasts of prey, and the eggs are collected or destroyed on the spot in great numbers, as on certain parts of the shores hundreds of turtles are known to deposit their eggs within the space of a

Chelonia.

mile. They form a new hole each time they lay, and the second is generally dug near the first, as if the animal were quite unconscious of what had befallen it. It will readily be understood, that the numerous eggs seen in a turtle on cutting it up could not be all laid the same season. The whole number deposited by an individual in one summer may amount to four hundred, whereas, if the animal is caught on or near her nest, as I have witnessed, the remaining eggs, all small, without shells, and as it were threaded like so many large beads, exceed three thousand. In an instance where I found that number, the turtle weighed nearly four hundred pounds. The young, soon after being hatched, and when yet scarcely larger than a dollar, scratch their way through their sandy covering, and immediately betake themselves to the water."

"The food of the green turtle consists chiefly of marine plants, more especially the grass-wrack (*Zostera marina*), which they cut near the roots, to procure the most tender and succulent parts. Their feeding grounds, as I have elsewhere said, are easily discovered by floating masses of these plants on the flats, or along the shores to which they resort. The hawk-billed species feeds on sea-weeds, crabs, various kinds of shell-fish and fishes; the loggerhead mostly on the fish of conch-shells of large size, which they are enabled, by means of their powerful beak, to crush to pieces with apparently as much ease as a man cracks a walnut. One which was brought on board the Marion, and placed near the fluke of one of her anchors, made a deep indentation in that hammered piece of iron that quite surprised me. The trunk-turtle feeds on mollusca, fish, crustacea, sea-urchins, and various marine plants. All the species move through the water with surprising speed; but the green, and hawk-billed in particular, remind you, by the celerity and ease of their motions, of the progress of birds through the air."¹

We shall add a few brief notices, chiefly to connect the preceding observations, and such as follow, with the systematic names bestowed by naturalists.

Our first species is *Chelonia mydas*, commonly called the green turtle, not so much by reason of its external colour, as because its fat, beloved by aldermen, assumes, when the creature is in high condition, a decidedly greenish hue. This tint is by some regarded as derived from its marine pastures, particularly *Zostera marina*, or turtle-grass, of which it is particularly fond. The shield of this species consists of thirteen plates, which do not lie over each other after the manner of tiles. Those of the central or upper line are almost in the form of regular hexagons. The green turtle is a reptile of gigantic proportions, sometimes measuring six or seven feet in length, and weighing seven or eight hundred pounds. Its flesh forms an agreeable and healthy aliment to sea-faring men in most of the seas of the torrid zone, and is still more highly prized by epicurean landmen. Its eggs are also most excellent as articles of diet. The introduction of turtle into Britain, as an article of luxury, is believed to be of no very distant date.

"Of the sea-turtles," says Catesby, "the most in request is the green turtle, which is esteemed a most wholesome and delicious food. It receives its name from the fat, which is of a green colour. Sir Hans Sloane informs us, in his History of Jamaica, that forty sloops are employed by the inhabitants of Port Royal, in Jamaica, for the catching them. The markets are there supplied with turtle as ours are with butchers' meat. The Bahamians carry many of them to Carolina, where they turn to good account; not because that plentiful country wants provisions, but they are esteemed there as a rarity, and for the delicacy of their flesh. They feed on a kind of grass growing at the bottom of the sea, commonly called turtle-grass. The inhabitants of the Ba-

¹ *Ornithological Biography*, ii. p. 370.

Chelonia. hama Islands, by often practice, are very expert at catching turtles, particularly the green turtle. In April they go in little boats to Cuba and other neighbouring islands, where, in the evening, especially in moonlight nights, they watch the going and returning of the turtle to and from their nests, at which time they turn them on their backs, where they leave them, and proceed on, turning all they meet; for they cannot get on their feet again when once turned. Some are so large that it requires three men to turn one of them. The way by which the turtle are most commonly taken at the Bahama Islands, is by striking them with a small iron peg of two inches long, put in a socket at the end of a staff of twelve feet long. Two men usually set out for this work in a little light boat or canoe, one to row and gently steer the boat, while the other stands at the head of it with his striker. The turtle are sometimes discovered by their swimming with their head and back out of the water, but they are oftenest discovered lying at the bottom, a fathom or more deep. If a turtle perceives he is discovered, he starts up to make his escape, the men in the boat, pursuing him, endeavour to keep sight of him, which they often lose, and recover again by the turtle putting his nose out of the water to breathe; thus they pursue him, one paddling or rowing, while the other stands ready with his striker. It is sometimes half an hour before he is tired; then he sinks at once to the bottom, which gives them an opportunity of striking him, which is by piercing him with an iron peg, which slips out of the socket, but is fastened with a string to the pole. If he is spent and tired by being long pursued, he tamely submits, when struck, to be taken into the boat or hauled ashore. There are men who by diving will get on their backs, and by pressing down their hind parts, and raising the fore part of them by force, bring them to the top of the water, while another slips a noose about their necks.¹

"The sea-tortoises, or turtles, in general," continues our author, "never go on shore but to lay their eggs, which they do in April. They then crawl up from the sea above the flowing of high water, and dig a hole above two feet deep in the sand, into which they drop in one night above an hundred eggs, at which time they are so intent on nature's work that they regard none that approach them, but will drop their eggs into a hat, if held under them; but if they are disturbed before they begin to lay, they will forsake the place and seek another. They lay their eggs at three, and sometimes at four different times, there being fourteen days between every time, so that they hatch and creep from their holes into the sea at different times also. When they have laid their complement of eggs, they fill the hole with sand, and leave them to be hatched by the heat of the sun, which is usually performed in about three weeks."

A still more gigantic species is the loggerhead-turtle (*Ch. caretta*, Gm.), distinguished by fifteen dorsal plates, of which the central are raised into a ridge. The upper portion of the muzzle is bent or beak-shaped, the anterior pair of feet are longer and narrower than in the allied species, and the two nails are persistent and better marked. It inhabits the tropical seas along with the preceding species, but extends into nearer northern latitudes, occurring occasionally in the Mediterranean. In a commercial point of view it is of little or no value, the flesh being coarse and rank, and the shell of no estimation. It furnishes, however, a useful lamp-oil. The loggerhead is said to be a bold and voracious reptile, feeding on shell-fish and other animal products, which it crunches with its strong bony beak. Al-

drovandus alludes to one which he saw exhibited alive in his days in Bologna. He held a thick walking-stick towards it, which it immediately bit in two. *Chelonia*.

The imbricated turtle (*Ch. imbricata*, Linn.) is so named on account of the mode in which its dorsal plates, thirteen in number, lap over each other, after the manner of tiles. (See Plate I., fig. 4.) Its muzzle is more prolonged than in many species, on which account it is sometimes named the hawk's-bill. Its mandibles are serrated. It measures from two to four feet, and occurs in the tropical seas. The flesh is disagreeable, and occasionally even dangerous, but the eggs are excellent; and its shield yields the finest quality of that valuable material in the arts called *tortoise-shell*. The lamellæ or plates are thicker, stronger, clearer, and more beautifully mottled than in any other species. The colours consist of an elegant undulation of white, yellow, red, and rich deep brown; but the article is too well known to require any detailed description. It is obtained by raising the fine external coating from the bony portion which it covers, by placing fire beneath the shell, which causes the plates to start and become detachable. They vary in thickness with the age and dimensions of the individual, and measure from an eighth to a fourth of an inch in thickness. A large turtle is said to afford about eight pounds weight of tortoise-shell; and Mr Schoepf states the range to be from five to fifteen or twenty pounds, adding, that unless the animal itself has attained the weight of a hundred and fifty pounds, the shell is of little value.

"In order," says Dr Shaw, "to bring tortoise-shell into the particular form required on the part of the artist, it is steeped in boiling water till it has acquired a proper degree of softness, and immediately afterwards committed to the pressure of a strong metallic mould of the figure required; and where it is necessary that pieces should be joined, so as to compose a surface of considerable extent, the edges of the respective pieces are first scraped or thinned; and being laid over each other during their heated state, are committed to a strong press, by which means they are effectually joined or agglutinated. These are the methods also by which the various ornaments of gold, silver, &c. are occasionally affixed to the tortoise-shell."

"The Greeks and Romans appear to have been peculiarly partial to this elegant ornamental article, with which it was customary to decorate the doors and pillars of their houses, their beds, &c. In the reign of Augustus this species of luxury seems to have been at its height in Rome."²

"The Egyptians," says Mr Bruce, in the supplement to his Travels, "dealt very largely with the Romans in this elegant article of commerce. Pliny tells us the cutting them for finearing or inlaying was first practised by Carvillus Pollio; from which we should presume that the Romans were ignorant of the art of separating the laminæ by fire placed in the inside of the shell when the meat is taken out. For these scales, although they appear perfectly distinct and separate, do yet adhere, and oftener break than split, where the mark of separation may be seen distinctly. Martial says that beds were inlaid with it. Juvenal, and Apuleius in his tenth book, mention that the Indian bed was all over shining with tortoise-shell on the outside, and swelling with stuffing of down within. The immense use made of it in Rome may be guessed at by what we learn from Velleius Paterculus, who says, that when Alexandria was taken by Julius Cæsar, the magazines or warehouses were so full of this article that he proposed to have made it the principal ornament of his triumph, as he did ivory afterwards

¹ One of the most remarkable modes of capturing turtles is that mentioned by Mr Salt. When that gentleman was at Mosambique he received a present of a fish of the genus *Echeneis*, which the inhabitants assured him they were in the habit of employing, by securing it by a cord to a boat, after which it would fasten itself by a sucker on the head to the breastplate of the first turtle it met with, and so firmly that the latter might be drawn towards the boat and captured.

² *General Zoology*, iii. 91.

Chelonia. when triumphing for having happily finished the African war."

But of all the marine tortoises, the coriaceous turtle (*Ch. coriacea*, Linn.) seems to attain to the greatest size, individuals having been met with measuring eight feet in length, and weighing about a thousand pounds. It differs from the rest of its tribe, as well in its more lengthened form and tapering termination, as in the softer or more leathery texture of its shield, which is not formed into distinct plates, but rather marked all over with small obscure subdivisions or lineations, which do not interfere with the general smoothness of the surface. There are also three raised longitudinal ridges, which run from above the shoulders to the posterior portion of the shield. (See Plate I., fig. 5.) This species inhabits the Mediterranean Sea, has been frequently taken even along the outer coasts of France, and occasionally makes its way to our own island shores. In the month of August 1729 a specimen was taken about three leagues from Nantes, near the mouth of the Loire. It measured above seven feet in length, and is said, when taken, to have uttered a scream so loud and hideous as to have been heard at the distance of a mile. Its mouth "foamed with rage, and exhaled a noisome vapour." It no doubt, and very naturally, objected to being lifted into a stinking slimy boat, from its own beautiful translucent sea. In the year 1778 a specimen was captured off the coast of Languedoc, which measured seven feet five inches; and, in 1756, another was taken on the Cornwall coast, which, Dr Borlase says, "measured six feet nine inches from the tip of the nose to the end of the shell, and ten feet four inches from the extremities of the fore-fins extended, and was adjudged to weigh eight hundred pounds." According to Lacépède, the coriaceous turtle is the species with which the Greeks were best acquainted, and he supposes it to have been particularly used in the formation of the ancient harp or lyre, which was originally constructed by attaching strings or wires to the carapace of one of these marine reptiles. "We may add," says Dr Shaw, "that the ribs or prominences on the back of the shell bear an obscure resemblance to the strings of a harp, and may have suggested the name of luth or lyre, *oy* which it is called among the French, exclusive of the use to which the shell was anciently applied." This turtle is reputed to be extremely fat, and it is eaten by the Carthusians, although its flesh is coarse and bad.

GENUS CHELYS, Duméril. Wide-mouthed turtles. This little group resembles the preceding genus *Emys* in the feet and claws. The carapace is much too small to admit of the withdrawal of the head and limbs, which are proportionally large. The muzzle is prolonged into a little trunk, but the most marked and peculiar character consists in the deeply cleft transverse gape, which is not armed with corneous mandibles, as in the other Chelonians, but rather resembles that of the Batrachian genus *Pipa*.

The best known and most noted species is the matamora (*T. fimbria*, Gm.), an animal of a very singular and rather repulsive aspect, first described by M. Bruguiere.¹ It measures about a foot and a half in length. Its carapace is oval, with raised pyramidal plates pointing backwards. The neck and other parts of the body are furnished with peculiar projecting fringes, or wart-like appendages. This reptile is native to Guiana, and was once common in Cayenne; but its numbers were long ago much thinned by the fishermen, who prize it as an excellent and nutritious food. It feeds on aquatic plants, and is said to wander by night to

some distance from the banks in search of pasture. The specimen described by M. Bruguiere was brought to him alive, and was sustained for some time on bread and herbs. It afterwards laid five or six eggs, one of which produced a young turtle.

GENUS TRIONYX, Geoff. Soft turtles. These have no plates or scales, but merely a soft skin enveloping their carapace and plastron, neither of which are completely supported by the bones, the ribs not reaching to the margins of the shield, nor being united to each other except by a portion of their length, and the parts analogous to the sternal ribs being replaced by simple cartilage, and the sternal pieces, partly toothed as in the marine species, by no means filling up the whole of the under surface. The feet, as in the fresh-water tortoises, are palmated though not elongated, and only three of the toes are furnished with nails. The corneous portion of the beak is clothed externally with fleshy lips, and the snout is prolonged. The tail is short. The species of this genus dwell in fresh waters, and the flexible margins of their carapace are of use in swimming.

The Egyptian species or tyrse, the *soft turtle* of the Nile (*Test. triunguis*, Forskal, *Tr. Ægyptiacus*, Geoff.), sometimes attains the length of three feet. Its shield is flattish, and of a green colour, spotted with white. This reptile devours young crocodiles the moment they are hatched, and, according to Sonnini, is more serviceable in this way than even the ichneumon.

An American species (*Tr. ferox*, Gmel.) inhabits the rivers of the new world, from Guiana as far north as the southern parts of the United States. It lies concealed in reeds and rushes, seizes on birds and reptiles, preying also on young caymans, and being in turn frequently devoured by the elder members of that powerful family. It is itself sought after as an article of food even by the human race, its flesh being by some esteemed equal to that of the green turtle. This species has been described as possessing considerable vigour and swiftness in its motions, and as springing forward when attacked to meet its assailant with fierceness and alacrity. It measures about a foot and a half in length, and seems to have been first described by Dr Garden in his correspondence with Pennant.²

ORDER II.—SAURIA. SAURIAN REPTILES.

In this order the heart is composed, as among the Chelonians, of two auricles and a ventricle, the latter being sometimes divided by imperfect partitions. The ribs are moveable, partly attached to the sternum, and are capable of being raised and depressed for the purposes of respiration. The lungs extend more or less towards the hinder portion of the body, and frequently enter far into the lower part of the abdomen. Those in which the lungs are large possess the singular faculty of changing the colour of their skin, according as they are excited by their wants or passions. The eggs are enveloped by a more or less consistent covering, and the young are produced in the perfect state, that is, they merely increase in size, without undergoing metamorphosis. The mouth is always armed with teeth; and the toes are furnished with nails, with very few exceptions. The skin is clothed with scales, or with little scaly granules. All the species have a tail, varying in length in the different kinds, but almost always thick at the base. The majority have four legs, although a few have only a single pair.

Sauria.
Crocodili-
dæ.

The Saurian order of reptiles was included by Linnæus under two genera, DRACO and LACERTA. The latter has been greatly subdivided, in accordance with the number of the feet, the form of the tongue, tail, and scales; and the formation of several separate families has resulted from the consideration of these important features. None of the saurian reptiles are venomous, although the bite of several of the larger kinds is to be avoided rather than otherwise. They all appear to be what may be called carnivorous; that is, they feed on living prey. Many assume the torpid state during the colder seasons of the year; but in their more active condition they affect, according to the species, a great diversity of situation; some haunting obscure and humid places, others rejoicing in a dry and sandy soil, exposed to the influence of the most radiant sun. Several are aquatic; while many climb trees, or, avoiding "leafy umbrage," seek the surface of exposed and barren rocks. Their form and outward adornment are as varied as their habits. Some are remarkable for beauty of shape and brilliancy of colour, while others present a repulsive aspect and a lurid hue. Many are extremely small, entirely innocent, and naturally familiar and confiding in their mode of life; others are of gigantic size, and distrustful and dangerous in their disposition. How great the difference between the beautiful, bright-eyed lizard, which suns itself beside a cottage window, and the huge cayman of America, stretched like a blackened log along the desolate shore of some forsaken river!

FAMILY I.—CROCODILIDÆ. CROCODILES IN GENERAL.

The *Crocodilidæ* take the first place in the Saurian order, a distinction to which they are well entitled from their great magnitude and strength, and a ferocity which has obtained for them the appellation of the tyrants of the fresh waters, both in the old and new world. They often attain the size of ten and twelve feet, frequently that of fifteen and twenty, and, more rarely, even that of twenty-five and thirty. Inhabiting the margins of the mighty streams of tropical climates, they are the terror of all who approach them; they prey upon every animal which comes within their reach; and man himself is not free from their attacks, for instances are by no means rare, both in ancient and modern times, of their suddenly seizing upon human beings, and carrying them off to their watery haunts. Hence these formidable animals are never witnessed, especially in temperate climates, but with the deepest interest. In the year 58 before the common era, the edile Scaurus exhibited at Rome five crocodiles from the Nile; on another occasion, Strabo mentions that the inhabitants of Denderah brought many to the great capital of the world; but the most astonishing spectacle of this sort ever witnessed was when the Emperor Augustus caused the Flavian Circus to be filled with water, and there displayed thirty-six crocodiles, which were killed by an equal number of men accustomed to fight with these monsters. Popular curiosity continues unabated; and the intimate connection of the creatures in question with geological investigations has more recently conferred upon them a very different but not less important interest.

The *Crocodilidæ* form an exceedingly natural group, closely associated by many common characters, of which the following are the most striking. They all attain a great size.

Their tail is compressed laterally. The fore-feet have five toes; the hind four, the three internal of which are furnished with nails, but all of them are more or less united by membranes. There is a single row of teeth in each jaw. The tongue is fleshy, flat, and attached by nearly the whole of its margin, a circumstance which led the ancients to believe that crocodiles were destitute of this member. The back and tail are covered with great scales or plates, which are often pointed in their centre; the scales on the abdomen are not so thick and strong.

The nostrils of these amphibious creatures open at the end of their snout by two small apertures, which shut with valves. The lower jaw is prolonged behind the cranium, which gives the appearance of motion to the upper jaw when the mouth is opened, an idea entertained by the ancients.¹ Their external ears are shut at will by two fleshy lips; their eye has three eyelids, two horizontal, like our own, and the third, a membrana nictitans, capable of being drawn from within outwards over the whole front of the globe. Beneath the lower jaw, on either side, is a gland, whose duct opens by a small slit a little within the lower edge of the jaw; it secretes an unctuous matter of a strong musky smell, and is supposed by Mr Bell (*Phil. Trans.* 1827) to be a bait for attracting fish towards the sides of the mouth. This gland, with others of a like nature situated elsewhere, confers a smell which pervades the whole animal. The vertebræ are to the number of sixty; seven are cervical, and these are so connected with each other by bony processes that they impede lateral movements, so that it is difficult for the animal to change its direction; and hence, when a person is pursued, he may easily escape by turning. Of all the Saurians, they are the only ones which are destitute of clavicles. Besides the ordinary supply of ribs, they have some which protect the abdomen without ascending to the spine. Their lungs do not descend into the abdomen, as in other reptiles of their order; and this, with their heart of three cavities, where the blood from the lungs does not mix with that from the body so freely as in the rest of the Reptilia, associates them somewhat nearer to warm-blooded animals.

It would be interesting, did space permit, to enlarge upon these physiological details. It is not a little curious, that in the animals belonging to this group, two openings are found, leading from the surface to the internal cavity of the abdomen, a structure similar to that which prevails in a few animals further down the scale. M. Geoffroy St Hilaire supposes that the superior energy of the crocodile in water is due to this penetration of that fluid, and the consequent conversion of the peritoneum into an additional respiratory surface. Another singular circumstance is, that these animals, as in some higher up the scale, are in the habit of swallowing great stones. An officer in the Colombian navy, who mentions this, tells us, that being somewhat incredulous on the point, he was satisfied of the fact by Bolivar, who, in order to convince him, shot several alligators with his rifle, and in the stomachs of all of them were found stones varying in weight according to the size of the animal. The largest killed was about seventeen feet in length, and had within him a stone weighing from sixty to seventy pounds. Upon their dispositions and habits we cannot greatly dilate.

In relation to the geographical distribution of the *Crocodilidæ*, we may here remark, that they are entirely foreign to Europe, and do not occur in New Holland, but are else-

Sauria.
Crocodili-
dæ.

¹ The peculiar structure of the jaws, and the nature of their movement, among these reptiles, have formed the subject of frequent argument. The fact, or rather the knowledge of it, although controverted by Perrault and Duverney, is as old as the time of Herodotus; and Aristotle asserts that they can move both jaws: *κινουμένην ὁδὴν τῶν σιαγόνων*. "Enfin, nous réviendrons encore sur la circonstance, tout-à-fait particulière, qui permet à la mâchoire supérieure, ou plutôt à toute la masse supérieure de la tête, de s'élever en bascule, et de se mouvoir ainsi sur la mâchoire inférieure quand celle-ci repose sur le terrain ou sur un plan fixé." (*Ergologie Générale*, iii. 25.) See also *Annales du Mus.* ii. 38.

Sauria.
Crocodili-
dæ.

where extensively spread over various regions of the earth. The caymans are peculiar to America, the crocodiles, properly so called, are common to both worlds, and the gavials have hitherto been found only in Continental India. The following table will show the distribution of the family, and the amount of species, in all the great divisions of our globe :

	Asia.	Both Asia and Africa.	Africa.	America.	Doubtful.
Cayman.....	0	0	0	5	0
Crocodile.....	2	1	1	2	2
Gavial.....	1	0	0	0	0
Total species ...	3	1	1	7	2=14

GENUS GAVIALIS, Cuv. and Geoff. We begin with the very limited genus GAVIAL, which, so far as known, is confined to the old world, if not to the Asiatic continent. The first description of one of these animals was given by our celebrated countryman Edwards.¹ Count Lacépède introduced the native name Gavial into our systematic works. The most recent researches of Cuvier have scarcely succeeded in determining whether there is more than one living species ; there appear, however, to be several fossil, and hence additional interest is excited.

In this genus the snout is slender, and very much prolonged ; the teeth are nearly uniform and alike ; the fourth of the under jaw, when the mouth is closed, locks not into a foramen in the upper jaw, but into a lateral groove only ; the hind feet are denticulated on the outer margin, and pal- mated to the extremity of the toes ; and there is a deep depression behind the eye.

G. longirostris, Cuv. ; *Crocodylus longirostris*, Schn. ; *Lacerta Gangeticus*, Gmel. *The Great Gavial*. The muzzle of this species is almost cylindrical, and somewhat bent at its extremity ; its head is singularly broad, especially towards the back part ; the length of its muzzle to that of its body is as one to seven and a half. Its dental formulary is $\frac{23}{2} = 106$. Its scales, as in all its congeners, supply excellent specific characters. This animal appears to attain a great size. Baron Cuvier received from Dr Wallich a specimen of an individual captured near Calcutta, which was seventeen feet long ; and from a fragment in the Paris museum, it is calculated it must sometimes attain to nearly double that size. Notwithstanding its great bulk, the very slender form of its muzzle renders it much less formidable than the other and more numerous genus (*Crocodylus*), which also frequents the Ganges. It feeds wholly upon fish, and is not regarded as dangerous to man, a fact confirmatory of Ælian's observation, that "there are two kinds of crocodiles in the Ganges, the one innocent, the other cruel." Though it has not hitherto been observed in other Asiatic rivers, it may reasonably be supposed to exist elsewhere than in the Ganges.

G. tenuirostris. Though the materials possessed by Baron Cuvier did not enable him to come to a definitive conclusion regarding the existence of the *small gavial*, yet upon the whole he favoured its claims to being something more than the young of the preceding species ; the existence of some nearly allied fossil kinds favouring the conclusion. There is no difference in the shape and arrangement of the teeth or scales ; and the greater narrowness of the upper and back part of the head, and of the orbital foramina, are the only specific differences supplied. Its average size has not been ascertained. Like the preceding, it frequents the Ganges.

GENUS CROCODYLUS, Cuv. The generic characters of the *true crocodiles* are sufficiently distinct. They do not possess the slender beak of the gavials ; the head is oblong,

Sauria.
Crocodili-
dæ.

and not half as broad as it is long ; the muzzle is oblong and depressed ; the teeth, which are somewhat unequal in their dimensions, are fifteen on each side in the lower jaw, and nineteen in the upper ; the fourth, which are the longest, pass into furrows, and are not lodged in distinct foramina of the upper jaw ; the hind feet have usually a denticulated crest at their outer margin ; and the interval of their toes, at all events the external ones, are palmated. There is a deep hollow behind each eye.

Different species of crocodile are found in the hot regions of Asia, Africa, and America. Many bear a very close resemblance to each other, but about eight seem to be satisfactorily established. These are, the species called *chamæses*, or *temsach*,—the common crocodile of the Nile ; the *hiporcatus*, or double crested ; the *acutus*, *rhombifer*, *galeatus*, and *cataphractus* (Cuv.) ; to which are to be added the *Gravesi* and *Journei* (of Bory de St Vincent). We begin with that which has been longest and perhaps is best known, the famous crocodile of the Nile.

C. vulgaris, Cuv. ; *Temсах* of the modern Egyptians ; *Lacerta crocodilus*, Linn. The length of the head of this species is double that of the breadth ; the snout is very ragged and unequal, especially in the old ; its eyes are more asunder than in other species. Without entering into minute details of the number and arrangement of the scales on the neck, back, tail, &c. we shall only state, that six rows of nearly equal-sized plates run all along the back, giving it the appearance of mosaic. The colour is a bronzed green, speckled with brown ; underneath it is a yellowish-green.

These animals sometimes attain the enormous size of thirty feet ; "and if we except," says Lacépède, "the elephant, the hippopotamus, some cetacea, and a few enormous serpents, they have no equal in nature." The female lays her eggs twice or thrice in the year, but only during the hot weather, and deposits them in the sand, where they are hatched by the sun. They amount to about twenty ; and are said to be hatched after fifteen or twenty days. They are about twice the size of the goose's egg, and it is stated that the mother takes no charge whatever of them. Indeed we believe that this maternal carelessness is characteristic of the reptile race.

This species is frequently designated the crocodile of the Nile, a name far from happy,—because other species may inhabit its waters, and the one in question may be more common elsewhere. There seems, indeed, to be no doubt that this same animal abounds in the Senegal and other rivers of Western Africa ; probably even in all the rivers of that continent, and certainly in those of Madagascar. Formerly it used to frequent the Nile as far down as the Delta, but now we must ascend to its less frequented portions before it is encountered. It was probably in reference to an individual of this species that Mungo Park relates the fact, that one of his guides across the river Gambia was suddenly seized by a crocodile and pulled under water. The negroes, however, are so familiar with these creatures, and so skilful in meeting their attacks, that they generally escape. On this occasion the negro thrust his fingers in the crocodile's eyes with so much violence that it quitted its hold ; but seizing him again, he resorted to the same expedient, and with more success, as it again released him, appeared stupified, and swam down the river. Although its flesh has a strong musky smell, yet the inhabitants of the districts wherein it abounds frequently attach a high value to it, as, according to the testimony of Herodotus, did also some of the ancient Egyptians. A common method employed by the Africans for destroying the crocodile is to thrust the arm, well defended with ox-hides, down its throat, and then to plunge a dagger into its vitals. The European

Sauria.
Crocodili-
dæ.

traveller will probably prefer avoiding such a close encounter.

Although we have hitherto treated of the common crocodile as one and distinct, yet it seems beyond doubt, that in the wide habitat assigned to it, many *varieties* at least exist. Cuvier remarks, that from the Senegal to the Ganges, and even beyond it, there are crocodiles very like the common one, which have the muzzle somewhat longer or narrower, and have slight differences in the scales of their neck and back, but which it is very difficult to distribute into distinct species. He himself was not able to establish any; nor could he with satisfaction adopt the four proposed by his eminent colleague M. Geoffroy, viz. *C. suchus*, *marginatus*, *lacunosus*, and *complanatus*.¹ Of these, by far the most famous is the *suchus*, which the last-named naturalist considers identical with the *sacred crocodile* of the ancient Egyptians. His theory is, that there existed a species of a small size, having a narrow snout, and a disposition which was wholly gentle and inoffensive, which affected the margin of the river, and was thus the precursor of its inundations; and that it was to this species that the Egyptians rendered divine honours. The opposing view, advocated by Cuvier, is that the favoured crocodile did not belong to any one species or variety more than another, and, far from being less, was even more ferocious; but that it was the custom of the priesthood to entertain, not a host of crocodiles, but only one, or a few, of any given variety, under the name of *souchis*, as the idol of a divinity who was represented by a crocodile's head; and that it was to this individual especially that divine honours were paid, in the same way as *apis* was the name of the sacred ox at Memphis, and *mnnevis* at Heliopolis. This favoured animal was always nourished and adorned with extreme splendour, and after its death was buried in the subterranean cells of the Labyrinth; whilst throughout the district where these honours were paid, the whole race of crocodiles were respected and preserved. Cuvier assigns the following among other reasons for the accuracy of his views, which we think conclusive: *First*, the crania of the buried and embalmed crocodiles do not belong to any one variety, but to all of them; and, *2dly*, there is the strongest historical proof that the crocodiles in those districts where they were worshipped, far from being less savage, were even more so than in others, because from their impunity they became more bold. Thus Ælian reports, that in the district of Tyntyrites, where they unsparingly destroyed the crocodiles, the inhabitants could bathe and swim in the river securely, whilst at Arsinoë they could not safely walk, far less draw water from the river's banks. The evidence that individuals, when taken young, may be completely tamed, is equally satisfactory. Thus Bruce relates, that on the western shores of Africa, the negroes bring up crocodiles, which become so gentle as to let children play with them and ride upon their backs; a fact which satisfactorily corroborates the accounts of those religious processions, &c. in which the sacred crocodile performed so essential and conspicuous a part.

C. biporcatus, Cuv. Dum; *C. porosus*, Schn. *Double crested crocodile*. This species is the common crocodile of India and its archipelago, frequenting the Ganges and other great rivers which empty themselves into the ocean, as also those of Corea and China, Ceylon, Java, Timor, &c. It has a strong resemblance to the Egyptian species; but the cervical scales are differently arranged, and the dorsal are smaller, more numerous, and differently shaped. (See Plate I., fig. 6.) The appearance of the pores between the scales is

much more conspicuous than in the other species, and grows with their growth. Its colour is brownish, with black bands on the back, and spots on the side. In the Paris museum there is one seventeen feet long, from the Ganges. In the account of Macassar, or Celbes, we read, that in the great river of that island, there are crocodiles so ferocious that they do not confine themselves to making war on fish, but assemble in troops to watch the boats, and endeavour to overturn them, that they may devour those who are in them. It is the opinion in Java that these animals do not devour their prey on capturing it; but bury it for a time in the mud, that it may decay. This remark is so generally made of other species in different parts of the world, that it would appear to be a prevailing habit among them.

C. acutus, Cuv. Dum. *The slender-snouted crocodile, or crocodile of St Domingo*. This slender-snouted crocodile is extremely common in the island of St Domingo, as well as in Martinique, and the northern parts of South America. Its most remarkable specific characters are the length of the muzzle, which is bulged at its base; and the scales of the back are differently disposed from those of the preceding. The upper part of the body is of a deep green colour, spotted and marbled with black; the under part is pale green. Dr Descourtils states that this animal is more flexible than is usually supposed, for it can introduce the extremity of its tail into its mouth. On the same respectable authority we learn that the males are not so numerous as the females; that they fight furiously at the season of reproduction; that the males are fit for generation at the age of ten, and the females at that of eight or nine, their fecundity not lasting more than four or five years,—a statement which may well be questioned. The eggs are deposited in spring, and hatched in a month. On issuing, the young are only nine or ten inches long; their growth continues for about twenty years, and some are as long as sixteen feet. At the time of the escape of the young, the female comes to scrape away the earth and let them out. She conducts, defends, and feeds them, by disgorging her own food for about three months, a space of time during which the male would seek to devour them.

C. rhombifer, Cuv. Dum. *Lozenge-scaled crocodile*. The habitat of this species has been ascertained only of late years. It occurs in the island of Cuba, and probably inhabits the other Antilles. Its specific characters are well marked. Its chanfrin is extremely prominent, forming a semicircle, whilst in the common crocodile it is only a gentle elevation; and the extremities are clad with much stronger and more projecting scales than in the other species. Its ground colour is green, bespeckled with small and very distinct brown spots.

C. galeatus, Cuv. Dum. *Helmeted crocodile*. The helmeted crocodile has been hitherto found only in Siam, and is remarkable for two bony triangular crests implanted, the one behind, the other on the middle line of the head. It has been taken ten feet long. *C. biscutatus* is now regarded as an anomalous variety of *C. acutus*. *C. cutaphractus*, the *cuirassed crocodile*, may be witnessed in the museum of the London Royal College of Surgeons, and it is very different, according to Cuvier, from all the others described. The source from whence it was obtained is unknown.² Its muzzle is longer and narrower than that of the St Domingo crocodile, whose peculiar chanfrin it wants. It is most easily distinguished by the armour on its neck; there are first two oval plates, then a row of four, then scaly bands common to the neck and back, which together form a cuirass as strong as that of any of the gavials or alligators.

dæ.

There still remain two other true crocodiles, described by M. Graves,¹ and which he regards as new; the *C. Gravesii* and *Journei* of Bory de St Vincent. Both of them are in the Bordeaux museum. The habitat of the former is believed to be the Congo, and of the latter America. All the bones of the *Gravesii* are as if pierced with small holes, a character they possess in common with some of the alligators. Its head is of the shape of a slender isosceles triangle; the extremity of the snout is rounded, and its surface covered with great obtuse tubercles, having no regular arrangement. The ninth, tenth, and eleventh teeth of the lower jaw are received into a furrow, as well as the fourth. The colour of the upper part is a dark deep brown, that of the lower a dull yellow. The snout of the *Journei* is very slender, approaching to that of the gavials; it is convex as well as long, and near its extremity is almost cylindrical. The back of this species is of a deep yellowish green; the flanks are yellowish, and the belly yellow.

GENUS ALLIGATOR, Cuv. The alligators are by far the most common representatives of this group in the new world; although, as we have already seen, there are true crocodiles in St Domingo, and probably in many other localities. In most parts of America they are known by the title of cayman, a name apparently of African origin, and applied by the negroes, not to the alligators only, but indifferently to every species of the group. It does not seem to be yet ascertained whether any true caymans are found in the old world. Adanson thought he discovered one in the Senegal; M. de Beauvais states that he saw one in Guinea; and Cuvier thinks it most probable that they have their representatives in our hemisphere. They possess all the power and ferocity of the true crocodiles, and in many places are found in astonishing numbers.

The head of the alligator is not so oblong as that of the true crocodile; the snout is broad and obtuse; the teeth are somewhat unequal, the number ranging from nineteen to twenty-two on each side of each jaw; the fourth of the under jaw is received, not into a lateral furrow of the upper one, but into a distinct foramen. Their feet are only semipalmated, and are not denticulated.

A. lucius, Cuv.; *Croc. Cuvieri*, Leach. *Pike-muzzled alligator*. This is peculiarly the alligator of the southern parts of North America, including Carolina, the Floridas, and Louisiana. In the Mississippi it ascends as far as the thirty-second degree north, a higher latitude than any species reaches in the old world. In these countries they frequent the muddy banks, and quite bury themselves in the cold season, falling into a lethargic state before the setting in of the frost.² This sleep is so profound that they may be almost cut to pieces without manifesting any sign of life; when the warm weather returns, they are soon roused into activity. According to Bosc, their eggs are white, and not larger than those of the turkey. They are good eating, and are prized by the natives, though they partake of the musky smell of the animal. As soon as they escape, the young betake themselves to the water; but the vast majority become the prey of turtles, fish, and amphibious animals, not excluding the older of their own species. During the first year they feed upon insects and very young fish. Bosc states that he preserved a brood of fifteen. They ate only living insects; and never captured them except when moving, upon which they darted at them with great velocity. They appeared quite gentle when he took them in his hand. At the end of the first year they are still very feeble creatures; during the second they acquire their formidable teeth. The duration of their existence is not precisely ascertained, but is supposed to equal

that of man. They never cast their skin; and on acquiring their full size, few animals can injure them. They can fast long. They live on frogs, fish, aquatic birds, on dogs, hogs, cattle, and any animal they can catch; when these go to the river to drink, they seize them by the muzzle or leg, and draw them into the water to drown them. "I used often," adds the traveller last named, "to amuse myself, bringing them from their retreats by making my dog bark. Sometimes I used to advance and strike them with my stick, at which they were little disturbed. They never thought of attacking me, and deliberately retired when they found their hunting promised no success." Though slow on land, they swim with great velocity. In Carolina they make deep burrows, where they pass the whole winter, and even the entire day in summer. Though usually met with on the edges of rivers and lakes, they are sometimes also found in ponds in woods. Bosc often attempted to take them with every kind of strong snare; but these were invariably broken to pieces. They are commonly taken with a strong hook baited with a bird or small quadruped, and connected by a chain to a tree. The Indians eat the tail only. At the time of reproduction they fight furiously with each other, and bellow as loud as bulls. They avoid the salt water and proximity to the sea, because they are there exposed to the attacks of sharks and the great turtle. In very warm districts in the Floridas, the rivers are sometimes quite crowded with them, so that they almost interrupt the navigation.

The specific characters of the pike-headed alligator are a flat snout, the sides of which are nearly parallel, uniting in front in a regular curve. There are eighteen transverse rows of scales on the back. The colour above is a deep greenish brown, beneath white tinged with green, and the flanks are regularly striated with the two colours. Catesby has seen them fourteen feet long. Its hide, except at particular spots, resists a musket ball; it is most vulnerable at the inferior part of the belly, and round the eye.

The great alligator of North America certainly forms one of the most remarkable features in the zoology of the United States. Whatever may be said of the African or South American species, this huge reptile is usually neither shy nor dangerous. Its ordinary motion on land is slow and sluggish, a kind of laboured crawling, which leaves the track of a lengthened trail upon the mud, like the keel of a small vessel. When met with at any distance from the water, it immediately squats, that is, lies as flat as it can, with its nose upon the ground, and staring around with rolling eyes. "Should a man approach them," says that accurate and admirable describer Audubon, "they do not attempt either to make away or attack, but merely raise their body from the ground for an instant, swelling themselves, and issuing a dull blowing sound, not unlike that of a blacksmith's bellows. Not the least danger need be apprehended; you either kill them with ease, or leave them." As if conscious of their incapacity of self-defence, they seldom travel except during the night, being then less subject to disturbance, besides "having a better chance to surprise a litter of pigs, or of land-tortoises, for prey." "In Louisiana," Mr Audubon observes, "all our lagoons, bayous, creeks, ponds, lakes, and rivers, are well stocked with them; they are found wherever there is a sufficient quantity of water to hide them, or to furnish them with food; and they continue thus in great numbers as high as the mouth of the Arkansas river, extending east to North Carolina, and as far west as I have penetrated. On the Red River, before it was navigated by steam-vessels, they were so extremely abundant, that to see hundreds at a sight along the shores, or on the immense rafts of floating or stranded timber, was

dæ.

quite a common occurrence, the smaller on the backs of the larger, groaning, and uttering their bellowing noise, like thousands of irritated bulls about to meet in fight;¹ but all so careless of man, that unless shot at or positively disturbed, they remained motionless, suffering boats or canoes to pass within a few yards of them without noticing them in the least. The shores are yet trampled by them in such a manner that their large tracks are seen as plentiful as those of sheep in a fold." It was in the Red River, it seems, that so many thousands of these reptiles were killed, while a mania prevailed for wearing boots and shoes made of *crocodile leather*. This had fairly become an article of trade, many of the squatters following for a time no other business. But this leather, though handsome and pliant, exhibiting all the regular lozenges of the scales, and capable of receiving the highest polish, is not sufficiently firm or close-grained to prevent for any length of time the ingress of damp or moisture.

The power of this alligator lies chiefly in his jaws and tail. The latter is admirably adapted to serve as an ally to the former, because when curved into a semicircle it sweeps everything towards the enormous mouth. "Woe be to him who goes within the reach of this tremendous instrument; for, no matter how strong or muscular, if human, he must suffer greatly if he escapes with life. The monster, as he strikes, forces all objects within the circle towards his jaws, which, as the tail makes a motion, are open to their full stretch, thrown a little sidewise to receive the object, and, like battering-rams, to bruise it shockingly in a moment. The alligator, when searching after prey in the water, or at its edge, swims so slowly towards it as not to ruffle the water. It approaches the object sidewise, body and head all concealed, till sure of his stroke; then, with a tremendous blow, as quick as thought, the object is secured." When these giant reptiles are engaged in fishing, the flapping of their tails upon the water may be heard at half a mile. In the vicinity of Bayou Creek, on the Mississippi, there are extensive shallow lakes and marshes, yearly overflowed by the dreadful flooding of that mighty river, and stored with myriads of fish of many different kinds—trouts, white perch, cat-fish, alligator-gars or devil-fish. Thither, in the heats of early autumn, after a burning summer sun has exhaled a quantity of water, the squatter, planter, hunter, all proceed in search of sport. The lakes are then not more than two feet deep, with a fine sandy bottom, and much grassy vegetation bearing seeds, keenly sought for by vast multitudes of water-fowl. In each lake is a deeper spot, called the Alligator Hole, because dug and dwelt in by these reptiles. There they may be seen in numbers lying close together. "The fish that are already dying by thousands, through the insufferable heat and stench of the water, and the wounds of the different winged enemies constantly in pursuit of them, resort to the alligator's hole to receive refreshment, with a hope of finding security also, and follow down the little currents flowing through the connecting sluices; but no! for as the water recedes in the lake, they are here confined. The alligators thrash them and devour them whenever they feel hungry; while the wood-ibis destroys all that make towards the shore. The hunter, anxious to prove the value of his rifle, marks one of the eyes of the largest alligator, and as the hair-trigger is touched, the alligator dies. Should the ball strike one inch astray from

the eye, the animal flounces, rolls over and over, beating furiously with his tail around him, frightening all his companions, who sink immediately; while the fishes, like blades of burnished metal, leap in all directions out of the water, so terrified are they at this uproar. Another and another receives the shot in the eye, and expires; yet those that do not feel the fatal bullet pay no attention to the death of their companions till the hunter approaches very close, when they hide themselves for a few moments by sinking backwards." So disinclined are they to attack the human race, that Mr Audubon and his companions have waded waist-deep among hundreds of them. The cattle-drivers may be often seen beating them away with sticks before crossing with their beasts, for they will readily attack cattle, and swim after such animals as dogs, deer, and even horses.

As soon as the cool autumnal air gives warning of the approach of frosty weather, alligators leave the lakes to seek for winter quarters, by burrowing beneath the roots of trees, or covering themselves with earth. They speedily become inactive; and to sit and ride on one, according to Mr Audubon, who never rows in the same boat with Squire Waterton, would now be no more difficult than for a child to mount a rocking horse. The negroes kill them by separating, at a single blow, the tail from the body. They are afterwards cut into large pieces, and boiled in a good quantity of water, from the surface of which the fat is collected in large ladles. A single man often kills above a dozen alligators in an evening, prepares his fire in the woods, and, by morning, the oil is rendered. This oil is used for greasing the machinery of steam-engines and cotton-mills; and formerly, when Indigo was made in Louisiana, it served (we know not how) to assuage the overflowing of the boiling juice, when a ladleful was thrown into the caldron. We would have deemed the remedy more dangerous than the disease. These reptiles emit a strong odour, and a large one may be discovered by it at a distance of sixty yards. The smell is musky, and, when strong, is insupportable. It is not, however, perceptible when they are in the water, "although I have," says Mr Audubon, "been so close to them while fishing, as to throw the cork of my line upon their heads to tease them." He adds, that he has regularly found in their interior round masses of a hard substance resembling petrified wood. He has broken these with a hammer, and found them brittle, and as hard as stones, which they outwardly resemble. "And as neither our lakes nor rivers in the portion of the country I have hunted them in, afford even a pebble as large as a common egg, I have not been able to conceive how they are procured by the animals if positively stones, or (if not) by what power wood can become stone in their stomachs." They are probably concretions formed of indigestible animal substances, or may themselves assist digestion.² Mr Audubon has often amused himself, when fishing where alligators abounded, by throwing an inflated bladder towards the one next him in the water. It makes for it at once, flapping it towards its mouth, and trying to seize it, but in vain. The light inflation floats aside, and in a few minutes many more of these huge creatures are seen attempting to master the delusive bladder, "putting one in mind of a crowd of boys running after a foot-ball." A black bottle is also sometimes thrown among them, tightly corked; but some one, more active than the rest, will seize it greedily, and the crunched

dæ.

¹ The majority of authors who have written of crocodiles from personal observation, agree regarding the frequent cries of the younger individuals, but seem to consider the older ones as seldom giving utterance to their feelings in that way. "Au contraire," says Humboldt, "le rugissement du crocodile adulte doit être très rare, car ayant vécu pendant plusieurs années ou en couchant à l'air libre sur les bords de l'Orénoque, nous avons été presque toutes les nuits entourés des crocodiles, nous n'avons jamais entendu la voix de ces sauriens à taille gigantesque." (*Recueil d'Observ. de Zoologie*, tom. i.)

² "Une particularité notable, mais qui paraît assez constante chez les crocodiles, puisque tous les auteurs qui en ont fait l'anatomie en ont fait mention, c'est qu'on trouve dans leur estomac des cailloux de différentes grosseurs, qui semblent devoir servir à la trituration des aliments, comme les petits pierres qui se rencontrent dans le gésier ou l'estomac musculueux des oiseaux." (*Eryptologie Générale*, iii. 27.)

dæ.

glass gives way within its ponderous jaws as easily as if ground in a coarse mill.

During the season of love, in spring, the male alligator is a fierce and dangerous animal, and possibly its observation by different naturalists, at different seasons of the year, may account for the contradictions which pervade the recorded statements of its life and manners. When thus excited, no man dares to swim or wade among them, or, as Mr Audubon quietly observes, "they are usually left alone at this season," a delicate piece of attention, which, we doubt not, like other virtues, is its own reward. The female prepares her nest about the first of June, choosing a place about forty or fifty yards from the water, in some thick bramble or cane, where she gathers leaves, sticks, and rubbish of all kinds, carrying the materials in her mouth as a hog does straw. As soon as a proper nidus is formed, she lays about ten eggs, which she covers over with more rubbish and mud; and proceeding in this manner, she deposits about fifty or sixty eggs in various layers. The whole is then covered up, matted, and tangled together with long grasses, in such a manner that it is extremely difficult to break it up. These eggs are in size like those of a goose, but of a longer form, and are protected rather by a parchment-like transparent substance than by shell. Though they are not eaten either by hogs or vultures, the female, now not only wary, but ferocious, watches near the spot, visiting the water from time to time for food. The nest is of course easily discovered, as she always goes and returns the same way, and soon forms a conspicuous path by the dragging of her giant form. According to Mr Audubon, to whom we stand indebted for these details, it is not the heat of the sun which hatches the eggs, but that of the nest itself,—a perfect hot-bed, from the mode of its formation. The young, as soon as excluded, force their way through the walls of their putrescent chambers, and issue forth all as beautiful and brisk as lizards. The female then leads them to the lake, or more frequently, for greater security, to some small detached bayou; for now the males, their own ungente fathers, will swallow them by hundreds, and the wood-ibis and sand-hill cranes devour them.¹

A. sclerops, Cuv.; *Croc. sclerops*, Schn. *Spectacled alligator*. This is more especially the alligator of Guiana and Brazil. Its snout, though broad, has not the sides parallel, as in the preceding, and is more triangular in its shape. The lower edge of the orbits are very prominent, and a crest projecting between them gives the appearance whence their specific name is derived. Its colour is bluish-green above, and irregularly marbled green and yellow, more or less pale, below. Azara speaks of a red variety, which is the most savage of all. It acquires a great size. Cuvier has seen it fourteen feet long; and in Surinam some have attained the length of twenty and twenty-four feet. In South America it extends as far as 32° south latitude, the same distance from the equator on the one side, as the preceding species reaches on the other. It cannot run half so swiftly as man, and rarely attacks him; but when the eggs are plundered, the female defends them courageously. She lays, according to some, as many as sixty, and covers them with a few leaves or a little straw. It passes the night in water, as Herodotus states of the crocodile of the Nile, and during the day basks in the sun on the banks. It has been stated, that in certain places, when the morass is partially dried, the remaining water is so crowded with caymans that nothing is to be seen but their projecting backs.

It was probably over this species (the *Yacare* of Azara, *Jacare noir* of Spix) that Mr Waterton obtained his far-famed and well-known conquest; and of it also that he relates the following anecdote. "One fine evening last year,

as the people of Angustura, said its governor, were sauntering up and down here on the bank of the Oronoco, I was within twenty yards of this place, when I saw a large cayman rush out of the river, seize a man, and carry him down, before any body had it in his power to assist him. The screams of the poor fellow were terrible as the cayman was running off with him. He plunged into the river with his prey; we instantly lost sight of him, and never saw or heard him more." The negroes of South America sometimes eat the flesh, notwithstanding its fetid and musky smell. Azara tells us that they succeed in sticking it with an armed harpoon, and after fatiguing it in the water, pull it out by main force and despatch it.

A. palpebrosus, Cuv. *Bony eyelid alligator*. The muzzle in this species is somewhat longer and less depressed than in the preceding, and the margins of the orbits are not projecting. The character, however, which at once distinguishes it from all the other Crocodilidæ is, that the upper eyelid is wholly occupied with an osseous plate, divided into three pieces by sutures. None of its congeners have more than a small osseous particle near the inner angle. Its teeth are $\frac{1}{2}$ on each side of each jaw. The interval between the two external toes is less palmated than in the other species, from which it may be concluded to be more terrestrial. This animal inhabits Cayenne, and exhibits considerable variation in its characters.

In addition to these clearly distinct species, naturalists now recognise the two following, viz. the dog-headed cayman, *Al. cynocephalus*, Dum. and Bib., and the black spotted cayman, *Al. punctulatus*, Spix.²

FAMILY II.—LACERTINIDÆ. LIZARDS IN GENERAL.

The members of this family are characterised by a slender extensile tongue, terminated by two filaments, like that of many snakes. All the four legs have five toes, separate, of unequal size, especially the hinder ones, and furnished with nails. The scales on the abdomen, and those beneath the tail, are disposed in transverse parallel bands. A produced portion of the skin, longitudinally cleft, and closing by a sphincter, protects the eye, beneath the anterior angle of which there is the vestige of a third eyelid. The false ribs do not form an entire circle.

The species of this family are numerous and diversified, and now constitute several generic groups. Like all other reptiles, they are much more abundant in sultry than in cold or temperate climates. "I am positive," says Mr Bruce, alluding to the lizard tribe in general, "that I can say without exaggeration, that the number I saw one day, in the great court of the temple of the sun at Balbec, amounted to many thousands; the ground, the walls, and stones of the ruined buildings were covered with them, and the various colours of which they consisted made a very extraordinary appearance, glittering under the sun, in which they lay sleeping and basking." He adds, that the desert parts of Syria, bordering on Arabia Deserta, abound with these reptiles beyond the possibility of calculation.

The genus *MONITOR* of Cuvier contains the largest species, some of them almost approaching to the size of crocodiles. They have teeth on both jaws, but none upon the palate. The greater number have the tail compressed, which aids their aquatic propensities. Their vicinity to water brings them into the frequent neighbourhood of crocodiles and caymans, and they are said to give warning of the approach of these formidable reptiles by a shrill whistle. Hence probably their name of monitor. That of *Tupinam-*

his, which they often bear, was bestowed upon them by an error of Seba's, who, misconstruing a passage in Margrave, applied to these reptiles the designation of a tribe of people.

The first subdivision of the genus contains the MONITORS properly so called (genus *VARANUS*, Dum.),¹ distinguished by small and numerous scales on the head, limbs, beneath the abdomen, and around the tail, the last-named portion being surmounted by a kind of keel formed by a double range of projecting scales. The thighs want the peculiar range of pores observable among several other groups of saurians. The species are confined exclusively to the ancient world, although Seba, and in later years Daudin, have stated the contrary. Travellers report that they prey on the eggs of water-fowl and on those of crocodiles, and that chameleons, young turtles, and fishes, have been found in their stomachs. M. Leschenault de Latour even states that they combine together on the banks of lakes and rivers for the purpose of attacking such quadrupeds as come to assuage their thirst, and that he has seen them attempt to drown a young stag which was trying to cross a river. He moreover found the thigh-bone of a sheep in one which he dissected.

The monitor of the Nile (*L. Nilotica*, Linn. *Varanus Niloticus*, Dum.), called *Ouaran* by the Arabs, has the teeth strong and conical, the posterior becoming rounded by age. The general colour is brown, with paler and darker points, forming various compartments, among which are transverse rows of large ocellated spots, which on the tail become ring-like. The tail is rounded at the base, and surmounted by a keel throughout its whole length. This species grows to the length of five or six feet. A vulgar belief prevails among the Egyptians, that it is a young crocodile hatched in drier earth than usual. Its figure is engraved on the ancient monuments of Egypt, probably in connection with the fact of its preying on the eggs of the crocodile. To the monitors also belong the animal called scink (*L. scincus*, Merr., but not of Linn., *Var. arenarius*, Dum.), a small species, very abundant in Libya, Syria, Egypt, and Arabia, where it frequents rather dry and sandy soils. It is called *Ouaran el hard* by the Arabs. Its teeth are compressed, cutting, and pointed, the tail almost without ridge, and a great part of it rounded. Its habits are more terrestrial than those of the preceding, and it may be regarded as identical with the land-crocodile of Herodotus. The jugglers of Cairo pluck out its teeth, and then employ it in the performance of tricks. Many other monitors are found both in Africa and India.²

The second subdivision of Baron Cuvier's monitors consists of such as have angular plates upon the head, and large rectangular scales beneath the abdomen and around the tail. The skin of the throat is clothed with small scales, and forms a couple of transverse folds. There is a row of pores upon the thighs.

This subdivision corresponds to the genus *TEYUS* of Merrem, and several minor groups may be indicated in it. For example, those called *Dracænæ* by Lacépède have the scales raised up into ridges, as among the crocodile tribe, and forming crests along the tail, which is compressed. An eatable species (*Mon. crocodilinus*, Merr.) occurs in Guiana, where it inhabits holes in the vicinity of marshes. It is said to swim with difficulty, to run rather swiftly, to climb trees with facility, and to bite severely. It attains the length of six feet, and is characterized by some scattered ridges of scales upon the back. Another and much smaller species (*Drac. bicarinata*) likewise inhabits South America. (See Plate II., fig 1.) The little group of safe-

guards (*Sauvegardes*, Cuv. the restricted genus *Monitor* of Fitzinger) have all the scales of the back and tail without ridges. Their teeth are dentated, although those of the back part of the mouth become rounded by use or age. Some have the tail more or less compressed, and the scales of the abdomen longer than broad. They dwell by the banks of rivers. Such is the very large variegated lizard (*L. teguixim*), well represented by Madame Merian at the end of her work on the insects of Surinam. It inhabits Brazil, Guiana, &c. where it attains the length of six feet. It runs rapidly, and plunges into the water when pursued, although it can scarcely be said to swim. It feeds on insects, reptiles, the eggs of poultry and of other birds, and is itself useful as an article of food. Others, distinguished by the name of *Ameiva*, scarcely differ from the preceding sections of the genus *TEYUS*, except in the tail being rounded, and no way compressed, and furnished, as well as the abdomen, with transverse rows of square scales. The scales of the abdomen are rather broader than long. The species of this little group may be regarded as the *lizards* of America, that is, as representing in the new world the reptiles which we so designate in the old; but they differ in wanting the molar teeth, the majority have no collar, and all the scales upon the throat are small. Their heads also are more pyramidal, and they want the osseous plate above the orbits. Several different species have been confounded under the title of *Lacerta ameiva*. The most generally distributed is that named *Teyus ameiva* by Spix. (See Plate II., fig. 2.) It is of a green colour, with vertical rows of white ocelli, bordered with black upon the flanks.

The genus *LACERTA*, Cuv., or lizards properly so called, forms the second principal group of the Lacertine family. They have the back part of the palate armed with two rows of teeth, and are further distinguished from the Ameivas and Safeguards by a collar beneath the neck, formed by a transverse row of broad scales, separated from those of the abdomen by a space, on which there are only minute scales, as on the throat. A portion also of the bones of the cranium projects over the orbits and temples, so that all the upper part of the head is provided with a bony buckler.

Lizards are remarkable for their lively movements, and light and elegant forms. Their colours are also often brilliant. They pass the winter in a state of torpidity, and are always active and vivacious in proportion to the power of the solar heat. They are often seen stretching themselves on rocks or stones, however heated, and brandishing from time to time their forked tongues, a motion which in some countries has induced the belief of their being venomous, an unfounded idea, we need scarcely say, no creatures being more innocent. They are by no means difficult to tame, but in a state of nature we have usually found them very timorous, although M. Bory St Vincent regards them as being as bold as they are beautiful. "Nous en avons vu plusieurs saisir bravement au museau des chiens d'arrêt qui les avaient surpris dans quelque pelouse sèche, et ne pas lâcher prise malgré les secousses violentes et les efforts que faisaient ces chiens pour se délivrer." They are by no means devoid of intelligence, and, though shy and fearful, are decidedly inquisitive in regard to what takes place around them. When raising themselves as high as their little limbs permit, in order to enlarge their "visible diurnal sphere," they often exhibit themselves to a quiet and concealed spectator in attitudes of great beauty. They frequently show themselves more alarmed for birds and quadrupeds than for the human race, and they will even acquire a certain degree of tameness when domiciled near

Sauria.
Lacertini-
dæ.

¹ The term *Monitor* is somewhat injudiciously applied to this restricted group, in as far as it does not contain the species originally so named, that is, the *grande sauvegarde d'Amerique*,—*Lacerta teguixim* of Linn. and Shaw.

² The genera *Varanus* and *Heloderma* form a distinct family (*Varanous*) in the system of MM. Duméril and Bibron. Of the former genus, four are Asiatic, two are from New Holland, one is from the Papous, one from Timor, and three are of African origin. *Heloderma horridum* (the sole species) is the only American member of the family.

the dwelling of a gently-disposed lover of nature. They fear cats and children. Lizards change their skins, like most other reptiles, and the difference between the brightness and brilliancy of their old and new attire has caused the description by naturalists of many species which have no foundation in reality. Although belonging to the cold-blooded classes, they are warmly attached to their females, and frequent battles take place among the males for the possession of their fair companions. The eggs are covered by a pale-coloured membranous skin, and are hatched by the heat of the sun, whether in the body of the basking parent, or after exclusion. The eggs themselves increase in size considerably, as the creature contained within develops its parts. The reptiles of this group are never voluntarily found in water. They dislike that element, and avoid it, being bad swimmers; nevertheless, when pursued down steepish banks, we have seen them swim across small ditches to gain the other side and avoid persecution. One of the most singular attributes of these creatures consists in their extreme fragility. When running up a bank, or otherwise attempting to escape from danger, if even a light glove or handkerchief is cast upon them, several inches of the terminal portion of their body comes riggling off, and will twist about among the grass for a considerable period with great liveliness, while the body with its head and four legs proceeds upon its way rejoicing. The tail even appears to rest itself from riggling for a time, and if touched with a pin, or otherwise incommoded, will then resume its movements with such an apparent character of discomposure, as if it were expressing its dislike at the annoyance.

Although several anatomists, proceeding upon their too exclusive knowledge of the higher classes of creation, in which there is no reproduction of important parts, have doubted the extent and universality of this inherent power in reptiles, there is yet no fact in natural history more satisfactorily determined. When we refer to the satisfaction of the subject, we allude chiefly to the feelings of the experimenter, those of the creatures in question being, we fear, in such a crisis, but sparingly consulted. In numerous reptiles, the limbs, and a great portion of the posterior part of the body, may be cut off without more than a temporary inconvenience, the removal being not only speedy, but complete. Blumenbach, one of our highest modern authorities, has repeated¹ the experiment alluded to by Pliny.² He destroyed with an iron point the eyes of the green lizard, and placing the poor creature in a vessel with some fresh earth, which he deposited in moist soil, he found, after the lapse of a brief period, that the organs of sight were entirely reproduced,—“in integrum restitutos.” Lizards and reptiles of the genus *Scincus*, of which the tail has been either intentionally or accidentally broken off, are found to reproduce it speedily. The newer portion is recognisable externally by the form and colour of the scales, and on dissection the vertebræ are found replaced by pieces of a more cartilaginous nature, which probably never acquire the hardness or consistency of bone. Many experiments have shown the facility with which the limbs and tail of water-newts, and other aquatic reptiles, may be reproduced.³ “Qu’il nous soit permis,” says M. Duméril, rather winningly, “de consigner ici une de nos expériences : nous avons emporté avec les ciseaux les trois quarts de la tête d’un triton marbré. Cet animal, placé isolément au fond d’un large bocal de crystal, où nous avons soin de conserver de l’eau fraîche à la hauteur d’un demi-pouce, en

prenant la précaution de la renouveler au moins une fois chaque jour, a continué de vivre et d’agir lentement. C’était un cas bien curieux pour la physiologie ; car ce triton privé de quatre sens principaux, les narines, la langue, les yeux, et les oreilles, c’était réduit à ne vivre extérieurement que par le toucher. Cependant il avait la conscience de son existence ; il marchait lentement et avec précaution ; de temps à autre, et à des grands intervalles, il portait le moignon de son cou vers la surface de l’eau, et dans les premiers jours on le voyait faire des efforts pour respirer. Nous avons vu, pendant au moins trois mois, se faire un travail de reproduction et de cicatrisation telle qu’il n’est resté aucune ouverture ni pour les poumons ni pour les aliments. Par malheur, cet animal a péri au bout des trois premiers mois d’observations suivies, peut-être par le défaut de soins d’une personne à laquelle nous l’avions commandé pendant une absence. Mais on a conservé le sujet dans les collections du muséum, et quand nous en parlons dans nos cours, nous le faisons voir à nu pour qu’on puisse constater la singularité du fait d’un animal qui a vécu sans tête, et surtout pour démontrer la possibilité et la nécessité, même chez les Batraciens, d’une sorte de respiration par la peau.”⁴

We may observe, that in all the tentative experiments which have been hitherto made upon this subject, it has been perceived that these renewals are favoured by warmth and retarded by cold. As an article of diet, lizards are scarcely ever used in Europe, unless in years of peculiar scarcity. Their flesh is said to possess a sudorific quality.

The species of this genus are numerous in many continental countries (from fifteen to twenty different European kinds being known to naturalists), but are few in Britain. Of the former, one of the most beautiful is the ocellated lizard (*L. ocellata*, Daudin), well known in Spain, Italy, and the south of France. It likewise occurs in Barbary, and, generally speaking, over a great portion of the basin of the Mediterranean ; but being extremely sensible to cold, it is not likely to extend into Kamtschatka, as some suppose. It may be kept alive within doors in Spain throughout the winter (it naturally then assumes the torpid state), but will perish if dug up from its retreat, and exposed to cold approaching to the freezing point. This magnificent reptile sometimes attains the length, even in Europe, of two feet, although its more usual length is from twelve to fifteen inches. Its proportions are rather ample, that is, somewhat thicker than usual, yet it is by no means devoid of elegance ; and although it can scarcely be said to be ornamented with those tints of azure, green, and gold, which Lacépède has lavished on it, with more of poetical fancy than precision, it yet is pleasingly adorned. The back is black, beset with numerous circles of green or yellow distributed in great profusion, and showing like pearly beads upon a darker ground. The head is beautifully marbled with green and black, as are also the upper portions of the thighs and feet. The tail is brownish, and all the under parts are of a greenish yellow. “Le lézard dont il est question est innocent, mais hardi ; il fuit au moindre bruit, non lâchement, s’arrêtant de distances en distances pour observer la cause de sa crainte, et si on le presse de trop près il se jette sur l’assaillant en faisant entendre un certain soufflement qui rappelle en petit celui qui font entendre les oies en colère. Comme on en trouvait beaucoup aux environs d’une baronnie de Saint Magne, où nous avons passé les premiers temps de notre jeunesse, et que nous en avons été souvent violem-

ment mordus en leur faisant la petite guerre que l'enfance livre à tout ce qui fuit, nous pouvons affirmer que leur dent ne produit aucun mauvais effet après la douleur du moment. Il suffit d'avoir vu un seul grand lézard vert, pour s'étonner que Linné ait pu confondre cette espèce avec le lézard gris.¹

It has been observed by the prince of Musignano (C. L. Bonaparte), that the Linnæan term *agilis* has been applied by the naturalists of different countries to that species of lizard which was most common or best known in their own. In this way several distinct kinds have been described under one name, and regarded as identical. The true *L. agilis* of Linn. is a northern species, which becomes rare in Italy, but is sufficiently common in France, and extends into Denmark and Sweden. Its history as a British reptile has been clearly illustrated only within a recent period by Mr Jenyns and others; for the so-called *L. agilis* of the generality of British authors ought not to be so named.² The actual species varies as usual in colour and markings; but the most common hue of the upper parts is sandy-brown, with obscure longitudinal fasciæ of a darker brown, and a lateral series of black rounded spots, each marked with a yellowish-white dot or line in the centre. "It is more timid," says Mr Bell, "and far less easily rendered familiar, than the beautiful green lizard (*L. viridis*) of Guernsey and the south of Europe. This latter species may be readily tamed, and taught to come to the hand for its food, and to drink from the hollow of the palm of any one to whom it is accustomed. It will lie coiled up between the two hands, enjoying the warmth, and not offering to escape. But it is very different from the present species, which appears not to be susceptible of any such attachment. It will indeed attempt to bite any one who handles it, which I have never known to occur with *L. viridis*. When in confinement it ceases to feed, conceals itself with extreme timidity when approached, and ultimately pines and dies." Mr Bell has bestowed the English name of sand-lizard on this *L. agilis*.

Our only other British species is the common viviparous lizard (*L. vivipara*, Jacquin, *Zootoca vivipara*, Bell³) confounded with the true *L. agilis* by many authors. "This agile and pretty little creature," Mr Bell observes, "is the common inhabitant of almost all our heaths and banks in most of the districts of England, and extending even into Scotland; it is also one of the few reptiles found in Ireland. On the continent its range does not appear to be very extensive; it is not found in Italy, nor, I believe, in

France, and is very probably confined in a great measure to our own latitude. Its movements are beautifully graceful as well as rapid; it comes out of its hiding-place during the warm parts of the day, from the early spring till autumn has far advanced, basking in the sun, and turning its head with a sudden motion the instant that an insect comes within its view; and, darting like lightning upon its prey, it seizes it with its little sharp teeth, and speedily swallows it." This species also varies greatly in its external aspect. The prevailing ground colour of the upper parts is greenish brown, with a dark brown dorsal line often interrupted; a broad fascia extends parallel with this on each side, commencing behind the eyes, and extending to a greater or less distance down the tail; and between these and the former are often one or more rows of black dots, and similar ones occur in many individuals in the broad lateral fascia. The under side of the body and base of the tail are orange, spotted with black in the male; in the female grayish brown without spots. In reference to Mr Bell's excellent account of this reptile, we take leave to add, that although it is no doubt entitled to the character of an ovo-viviparous species, the young are not always born at once from the body of the mother, that is, already freed from the encumbrance of the egg. We have several times kept gravid females in our possession, and on two occasions the membranous eggs were deposited unbroken, and the young lay within them for from two hours till a day and a half before they made their appearance. Their movements, however, were visible through the walls of their prison from the moment they were laid.

The more limited genus *ALGYRA* of Cuvier has the tongue, teeth, and pores of the lizards; but the scales on the back and tail are ridged, those on the abdomen smooth and imbricated, and the collar is wanting. In the genus *TACHYDROMUS*, Daudin, the scales on the back, and those beneath the tail and abdomen, are square and ridged; the collar on the neck is absent, as well as the pores on the thighs, but on either side of the anal aperture there is a vesicle opening by a pore. The body and tail are both much elongated. The species run with great swiftness. See Plate II., fig. 3.)

FAMILY III.—IGUANIDÆ. IGUANAS.⁴

In this family the general form, the lengthened tail, the free and unequal toes, resemble those parts in the lizard

¹ *Dictionnaire Classique d'Hist. Nat.* ix. 339.

² See Jenyns's *British Vertebrate Animals*, p. 291; and Bell's *History of British Reptiles*, p. 22.

³ Mr Bell assigns as one of the generic characters by which this species differs from his restricted genus *Lacerta*, that the palate is toothless, while it is armed in that last named.

⁴ The great family of the IGUANIDÆ is divided by MM. Duméril and Bibron into forty-six genera, containing 146 species, the detailed descriptions of which occupy about 550 closely-printed pages in the work of those authors. (See *Erpétologie Générale*, tom. iv.) We regret that our restricted limits debar us from following their extended system, but we shall here present a tabular view of the genera and amount of species, partitioned in accordance with their geographical distribution.

Sauria. tribe, and the eyes, ears, and other characters are similar, but the tongue is thick, fleshy, not extensile, and, instead of being terminated by two filaments, is merely notched at the extremity.

SECT. 1.—*No teeth on the palate.* AGAMIANS, Cuv.

a. Tail surrounded by rings composed of large scales, which are frequently spiny. *Stelliones*, Cuv.

In the genus *CORDYLUS* of Gronovius, not only the tail, but even the back and abdomen, are furnished with large scales placed in transverse rows. The head, as in the common lizards, is provided with a bony buckler, and covered with plates. In several species the points of the scales of the tail form spinous circles, and there are also little spines on the sides of the back, on the shoulders, and outside the thighs. The last-named parts have a line of very large pores. The Cape of Good Hope produces several species, which have been long confounded in systematic works under the name of *Lacerta cordylus*, Linn. They are somewhat larger than the common green lizard of Europe, and like it feed on insects.

In the genus *STELLIO* of Daudin, the spines of the tail are of medium size, the back part of the head is bulged by the muscles of the jaws, the back and thighs are here and there beset with scales of larger size, sometimes spiny, and little groups of spines surround the ears. The thighs want the pores. The tail is long and pointed. Only a single species seems distinctly known to naturalists,—*St. vulgaris* (*L. stellio*, Linn.), a reptile very common in Egypt, and throughout the Levant. It measures about a foot in length, and is of an olive hue shaded with black. It is the *koscordylus* of the modern Greeks (*hardun* of the Arabs), and is not unfrequently named the rough lizard, in consequence of the unusually hispid appearance of the whole of its upper surface. The Mahomedans slay this species wrathfully, from a feeling that a peculiar downward inclination of its head is in mockery of their own reverential motions while engaged in prayer. The species called *stellio* by ancient writers was so named on account of its being

marked by spots resembling stars, and was probably in no way allied to the genus to which in after times the title was applied.

The genus *DORYPHORUS*, Cuv. (a name too nearly resembling one already bestowed upon a group of insects), resembles the preceding in the absence of pores, but the body is not beset with groups of spines. (See Plate II, fig. 4.) The azure lizard (*L. azurea*, Linn.) may serve as an example. The genus *UROMASTIX*, Cuv., may be described as composed of stellions, of which the hind head is not inflated; all the scales of the body small, smooth, and uniform, except those of the upper surface of the tail, which are large, spiny, and projecting. There is a series of pores upon the thighs. *Stellio spinipes* of Daudin is a *Uromastix*. It is found in the deserts which encompass Egypt, and is supposed by Belon, although without sufficient proof, to have been the *land-crocodile* of the ancients. It measures from two to three feet, has an inflated body of a fine grass-green colour, with small spines upon the thighs, as well as on the upper portion of the tail.

b. Scales on the tail imbricated. *Agamæ*, Daud.

In the ordinary or restricted genus *AGAMA*, scales raised into points or tubercles beset different parts of the body, and especially the ears, with spiny projections, isolated or in groups. There is sometimes a row upon the nape of the neck, but not forming a compressed crest as in *Calotes*. The skin of the throat is loose, transversely folded, and susceptible of dilatation. A species from New Holland (*Ag. barbata*, Cuv.) is remarkable for its size and extraordinary formation. A series of large spiny scales, disposed in transverse bands, prevails along the back and tail. The throat, often much inflated, is furnished with long pointed scales, forming a kind of beard-like appendage; and similar scales beset the sides, and form two oblique crests behind the ears. There are yellow spots upon the abdomen, bordered with black. Another of this genus is the muricated lizard of Shaw (*L. muricata*), likewise a native of New Holland. In some the body is enlarged or inflated, so as

Sauria.
Iguanidae.

to appear orbicular, as in *A. orbicularis*, a South American reptile, which, from its thickened form and broadened head, seems at first sight a connecting link between the frogs and lizards.

The genus *TRAPELUS*, Cuv., has the teeth and general form of *Agama*, but the scales are small and spineless. There are no pores on the thighs. *T. Egyptus*, Geoff., is a small species, in which the body is sometimes inflated. It can change its colour even more rapidly than the chameleon. This genus is not easily distinguished from some thick and slightly spined species of *Agama*, to which indeed the genera *Leiolepis*, *Tropidolepis*, and *Leposoma*, are nearly allied, and for the descriptive characters of which we may refer the reader to systematic works. The genus *CALOTES*, Cuv., differs from *Agama* in being regularly covered with scales disposed tile-ways, often keeled and pointed, as well on the body as on the limbs, and tail, which is of great length. The scales on the middle of the back are more or less raised and compressed, forming a crest or ridge of variable extent. There are neither wattles nor pores upon the thighs, —characters which sufficiently distinguish them from the *Iguanas proper*. The best-known species is that called the galeot lizard (*L. calotes*, Linn.), of a variable colour, but usually of a fine light blue, with transverse lines of white upon the sides. There are two rows of spines behind the ear, and a lengthened ridge along the back. Its eggs are fusiform, or spindle-shaped. This curious reptile is native to the East Indies, and is called *chameleon* in the Moluccas, though it scarcely changes its colour. It is said to wander about upon the roofs of houses in quest of spiders; and Lacépède observes that it is reported to prey even on rats, and to fight with serpents. When out of temper, its throat becomes so inflated as to give it a frightful aspect. If authors are correct, its distribution must be very extensive, as it is said to occur not only in the East Indies, but in Arabia and Barbary. It certainly, however, does not inhabit Spain, as some have said. In the genus *LOPHYRUS*, Duméril, the scales of the body resemble those of *Agama*, and the palisade-like ridge upon the back is even higher than in *Calotes*. The tail is compressed. To this genus belongs *Agama gigantea* of Khul, remarkable for the height of its crest above the neck. Two bony ridges continued from the muzzle terminate in a point on each side above the eye, and join upon the temples. It is a native of India. In *LYRIOCEPHALUS*, Merrem, we find a species in which the bony crest above the eyes is even more marked than in the preceding, and terminates behind on each side in a sharp point. This strange reptile is found in Bengal and other parts of the East, and is said to live on grain. (See Plate II., fig. 5.)

The preceding generic groups, from *Agama* downwards, are all more or less allied to the *Agamæ* of Daudin. We now proceed to a brief consideration of certain genera, of which the relationship is more remote.

The genus *ISTIVRUS* of Cuvier is distinguished by an elevated cutting crest, which extends to a portion of the tail, and is supported by the high spinal processes of the vertebræ. This crest is scaly like the rest of the body, and the scales of the abdomen and tail are small, and rather of a square form. There are no teeth on the palate, but those of the other parts of the mouth are strong, compressed, and without dentation. The thighs bear a row of pores. The skin of the throat is loose, but does not form a dewlap. To this genus belongs that very remarkable animal the Amboyna lizard (*L. Amboinensis*, Gm.), first described by Valentyn, and afterwards with great accuracy and an excellent figure by Dr Albert Schlosser in 1768. The back is spined, but the regular ridge only commences at the base of the tail, over a portion of which it extends, like a broad upright fin. The head and neck are green, varied by transverse whitish undulations; the back and tail

are brown, with a slight cast of blue or purple; and the sides and abdomen are grayish, spotted by means of round white scales. It resides, according to Valentyn, in the vicinity of fresh waters, and is frequently observed on the banks of rising grounds as well as on the lowlier kinds of shrubs which vegetate near the water, but does not ascend the taller trees. When disturbed by the approach of man or beast, it instantly dives, and hides itself among the rocks or stones beneath the banks. When captured, it does not in any way defend itself, but seems stupefied. It may be caught by a noose or snare, and its flesh is said to be white and sweet, although of a penetrating odour. It is highly esteemed as food by many, and is itself accustomed to prey both on insects and vegetable substances. It sometimes attains a length of nearly four feet.

The genus *DRACO*, Linn., may be distinguished at a glance from all other Saurian reptiles, by the singular peculiarity of six false ribs, which, instead of conforming as usual to the shape of the body, extend from it at right angles, and supporting a produced portion of the skin, present the appearance of a pair of wings. They support the animal in the air, as it leaps from branch to branch, but have no propelling power, and so cannot raise it in the least degree. In relation to their other characters, these so-called dragons are of small size, and covered all over by imbricated scales, of which those on the tail and limbs are keeled. The tongue is fleshy, not very extensile, and slightly notched. Beneath the throat there is a long pointed dewlap, supported by the tail of the hyoid bone; and on its sides are two others of smaller size, sustained by the horns of the same bone. The tail is long; there is a small dentation on the nape of the neck; and the thighs have no pores. Each jaw is furnished with four small incisor teeth, with a pair of long-pointed canines, and twelve triangular three-lobed grinders. The genus may be said to combine the scales and dewlaps of the *Iguanas*, with the head and teeth of the *Stellions*. (See Plate II., fig. 6.)

All the known species of *Draco* inhabit the East Indies, and have derived their generic appellation from their supposed resemblance to the fictitious Dragons of antiquity. In all ages, and in most countries, the imagination of timid or fantastic men has produced a belief in the existence of fabulous beings, of monstrous forms and irresistible ferocity, which carried devastation into provinces, guarded the entrance to sacred places, or watched over "sunless heaps" of hidden gold. The heroic history of Greece, and the darker superstitions of the Germanic people, are alike pervaded by these fond beliefs. "Rendered celebrated," says Lacépède, "by the songs of Greece and Rome, the principal ornament of pious fables imagined in more recent times, conquered by heroes, and even by youthful heroines, who were contending for a divine law, and adopted by a second mythology, which placed the fairies on the throne of the enchantress of old, the Dragon became the emblem of the splendid actions of valiant knights, and has enlivened modern as it animated ancient poetry. Proclaimed by the severe voice of history, everywhere described, everywhere celebrated, everywhere dreaded; exhibited under all forms, always clothed with tremendous power, and immolating his victims by a single glance; transporting himself through the midst of clouds with the rapidity of lightning, dissipating the darkness of night by the terrific splendour of his glaring eyes, uniting the agility of the eagle, the strength of the lion, and the magnitude of the giant serpent; sometimes presented under a human figure, endowed with an intelligence almost divine, and adored, even in our own days, in the great empires of the East,—the Dragon, in short, has been all in all, and everywhere to be found, except in nature."

The existence of these animals has not been altogether discredited even in modern times. About the middle of

Sauria.
Iguanidae.

Sauria.
Iguanidæ.

last century, a Hamburg merchant greatly prided himself on the possession of a famous dragon, which he valued at 10,000 florins. It was however discovered by the penetrating eye of the then youthful Linnæus to be a gross deception, formed by a combination of the skins of snakes, the teeth of weasels, and other absurd and heterogeneous elements, "non Naturæ sed artis opus eximium." It is said that the great Swedish naturalist was obliged to flee the city to avoid the wrath of the enraged proprietor. A similar fraud seems to have been practised in our own country towards the close of the seventeenth century, and is thus related by Dr Grainger, from a note of Dr Zachary Grey, in his edition of Hudibras. "Mr Smith of Bedford observes to me, on the word *dragon*, as follows: Mr Jacob Robart, botany professor¹ of Oxford, did, about forty years ago, find a dead rat in the Physic Garden, which he made to resemble the common picture of dragons, by altering its head and tail, and thrusting in taper sticks, which distended the skin on each side, till it mimicked wings. He let it dry as hard as possible. The learned immediately pronounced it a dragon; and one of them sent an accurate description of it to Dr Magliabechi, librarian to the Grand Duke of Tuscany; several copies of verses were wrote on so rare a subject; but at last Mr Robart owned the cheat; however, it was looked upon as a masterpiece of art, and as such deposited in the museum, or anatomy school, where I saw it some years after."

We need hardly here observe, that the actual dragons, or *Dracones* of naturalists, are harmless animals, of small size though extraordinary forms, which inhabit chiefly the insular forests of the Indian Ocean. (See Plate II., fig. 6.) In these umbrageous places they pursue their insect prey, descending but rarely to the ground, on which they walk with difficulty. According to Van Ernest, a Dutch naturalist, they couple among the branches, and the female deposits her eggs in hollow trees, under favour of a south exposure. We are doubtful regarding their amphibious propensities, as reported by M. Palisot de Beauvois, who remarked one in the *kingdom of Benin*, which he was unable to procure, because it was swimming in the water. Now Baron Cuvier states that "les espèces connues viennent toutes des Indes Orientales."

Three distinct species of *Draco* are described by M. Daudin, who was the first to discriminate their characters. *D. lineatus* (volans, Linn.) has the body varied above with blue and gray, the wings brown, with longitudinal stripes of white. *D. viridis* is green, the wings gray, with brown bands. This is the species described by Seba under the name of *winged dragon of America*, and afterwards figured by that author as the *flying dragon of Africa*, in neither of which countries is it ever found. It is said by Bontius to be not uncommon in Java, where it will shoot from tree to tree for a distance of thirty yards, producing a perceptible noise by the vibration of its wings. With a view to render itself specifically lighter, it inflates its yellowish goitres when it flies. *D. fuscus* is brown above, paler beneath; the wings likewise brown. Eight species are now known to naturalists.

The genus *SITANA*, Cuv., possesses the teeth of the preceding; the limbs and body are covered with scales imbricated and keeled, the thighs are without pores, but the false ribs are not expanded. The species are distinguished by an enormous dewlap, which extends as far as the middle of the abdomen, and is more than twice the height of the body. We know not that there is any other described than the Pondicherry species (*Sit. Ponticeriana*), a small reptile of a fawn-colour, with a range of large rhomboidal spots along the back. (See Plate II., fig. 7.)

SECT. 2.—*Teeth on the Palate.*

Sauria
Iguanidæ

Genus IGUANA, Cuv. *Iguanas properly so called.* These have the body and tail covered with small imbricated scales. A row of spines or raised scales, compressed and pointed, prevails along the back; and beneath the throat there is a compressed and pendant dewlap, or gular pouch, of which the margin is supported by a cartilaginous production of the hyoid bone. The thighs bear a line of tubercular pores like those of lizards, and the head is covered with plates. Each jaw supports a range of compressed triangular teeth with dentated cutting edges, and there are moreover two small rows of teeth on the posterior margin of the palate.

The common iguana (*I. tuberculata*, Laur., *Lac. iguana*, Linn.) is naturally of a greenish-yellow colour above, mottled with pure green, the tail ringed with brown; the under parts of a paler hue. The scales of the dorsal crest are large and spinous, and there is a conspicuous rounded plate beneath the tympanum, at the angle of the jaws. The sides of the neck bear some pyramidal scales mingled with the others, and the anterior edge of the dewlap is dentated like the back. This species measures from four to five feet in length, and is extensively spread over many of the warmer countries of America, where it is held in high esteem as an article of diet, though by many regarded as by no means healthful. It dwells chiefly among trees, feeding on fruits, grain, and leaves, and is sometimes seen to enter the water. The female deposits her eggs in the sand. They equal in size those of a pigeon, have scarcely any albumen, and afford excellent eating. The common method of catching this reptile is by casting a noose over its head, and then drawing it from its position. It seldom makes an effort to escape, but stands staring at its antagonist, at the same time inflating its throat in a most extraordinary manner.

"Guanas," says Catesby, "are of various sizes, from two to five feet in length; their mouths are furnished with exceeding small teeth, but their jaws armed with a long beak, with which they bite with great strength; they inhabit warm countries only, and are rarely to be met with anywhere north or south of the tropics. Many of the Bahama Islands abound with them, where they nestle in hollow rocks and trees; their eggs have not a hard shell, like those of alligators, but a skin only, like those of a turtle, and are esteemed a good food. They lay a great number of eggs at a time in the earth, which are there hatched by the sun's heat. These guanans are a great part of the subsistence of the inhabitants of the Bahama Islands, for which purpose they visit many of the remote *kayes* and islands in their sloops to catch them, which they do by dogs trained up for that purpose, which are so dexterous as not often to kill them, which, if they do, they serve only for present spending; if otherwise, they sew up their mouths to prevent their biting, and put them into the hold of their sloop till they have caught a sufficient number, which they either carry alive for sale to Carolina, or salt and barrel up for the use of their families at home. These guanans feed wholly on vegetables and fruit, particularly on a kind of fungus growing at the roots of trees, and on the fruits of the different kinds of *annonas*. Their flesh is easy of digestion, delicate, and well tasted; they are sometimes roasted; but the more common way is to boil them, taking out the leaves of fat, which are melted and clarified, and put into a calabash or dish, into which they dip the flesh of the guana as they eat it. It is remarkable that this fat, which adheres to the inside of the abdomen, imbibes the colour of the fruit the animal eats last, which I have frequently seen tinged of a pale red, yellow, or sometimes of a purple colour, which last was from eating the *prunus maritima*, which fruit, at the same time, I took out

¹ He was rather superintendent of the garden than professor properly so called.

Sauria.
Iguanidæ.

of them. Though they are not amphibious, they are said to keep under water above an hour. When they swim, they use not their feet, but clap them close to their body, and guide themselves with their tails; they swallow all they eat whole. They cannot run fast, their holes being a greater security to them than their heels. They are so impatient of cold that they rarely appear out of their holes but when the sun shines."

"The guana," observes Browne, in his Natural History of Jamaica, "like most of the tribe, lives a very considerable time without food, and changes its colour with the weather, or the native moisture of its place of residence. I have kept a grown guana about the house for more than two months; it was very fierce and ill natured at the beginning, but after some days it grew more tame, and would at length pass the greatest part of the day upon the bed or couch, but it went out always at night. I have never observed it to eat anything, except what imperceptible particles it had lapped up in the air; for it frequently threw out its forked tongue, like theameleon, as it walked along. The flesh of this creature is liked by many people, and frequently served up in fricassees at their tables, in which state they are often preferred to the best fowls. The guana may be easily tamed while young, and is both an innocent and a beautiful creature in that state."

The horned iguana of St Domingo (*Ig. cornuta*, Cuv.) is distinguished from the common kind by an osseous conical point between the eyes, and two raised scales upon the nostrils. The neck is not tuberculated. This species measures about four feet in length, and is frequently found on the hills of St Domingo, between Artibonite and Gonaives. It lives on fruits, insects, and small birds, which it seizes with surprising agility, and during the day it couches on trees and rocks to watch for its prey. During the night, and throughout the greatest heats of the hot season, it retires among the chambered rocks, or into the hollows of old trees, and there passes many months in a state of lethargy. This iguana is considered by the negroes as a great delicacy, and they accordingly search for it with avidity. According to the report of the colonists, its flesh resembles in flavour that of the roe-buck, and the maroon dogs make great slaughter among these reptiles.¹

The naked necked iguana (*Ig. nudicollis*, Cuv.) resembles the preceding species in its dorsal crest, but it does not possess either the large plates beneath the tympanum, nor the scattered tubercles on the sides of the neck. The upper part of the cranium is furnished with gibbous plates, the occiput is tubercular, and the dewlap or gular pouch is slightly dentated, and only on its anterior portion. Its native regions are Brazil and Guadaloupe, not India, as Laurenti supposes. (See Plate II., fig. 8.) Several other species are described by naturalists.

In the genus *Ophryessa*, Boié, the scales are small and imbricated; a dorsal crest, not greatly projecting, is prolonged upon the tail, which is compressed. The teeth resemble those of the preceding genus, but there is neither dewlap nor pores. The supercilious lizard of the older authors (*Oph. superciliosa*) may be named as an example. It is an American species, of a fawn-colour, with a festooned band of brown along the flanks, and measures from twelve to sixteen inches. It derives its specific name from a peculiar membranous ridge which occupies the region of the eyebrow.

The genus *Basiliscus*, Daudin, has the scales of small size, and the raised ridge on the back and tail is continuous, and supported by the spiny processes of the vertebræ, after the fashion of the tail in the Amboyna lizard, as already mentioned in our brief notice of the genus *Istiurus*.

The name of Basilisc as naturally recalls to mind the fabled stories of antiquity as that of Dragon. It was supposed to be the most poisonous and malignant of creatures, its very aspect being regarded as fatal to the unhappy beholder. It exercised its tyrannous sway amid the burning and desert sands of Africa, and obliged each meaner reptile to keep at a respectful distance.

Sibilaque effundens cunctas terrentia pestes,
Ante venena nocens, late sibi submovet omne
Vulgus, et in vacua regnat Basiliscus arena.

Sauria.
Iguanidæ.

But the animals now known to naturalists under the name of Basilisc, we are happy to say, are harmless creatures, of very innocent manners, although of most extraordinary aspect. They do not occur in Africa, as Lucan feigns, nor in India, as Seba alleges, but in South America, especially Guiana, as Daudin has determined. The best known is the mitred species (*B. mitratus*, *L. Basiliscus*, Linn.), distinguished by a membranous crest upon the occiput, somewhat in the form of a cowl or hood, and supported by cartilage. It is of a bluish colour, with two white bands, one behind the eye and another behind the maxillæ. It measures from two to three feet in length, and feeds on grains.

In the genus *POLYCHRUS*, Cuv. there is no dorsal crest, the head is covered with plates, and the tail is long and slender. The extensile skin of the throat is capable of being formed into a gular pouch at the will of the animal, and this genus possesses the power of changing colour like the cameleons. Their lungs are likewise very voluminous, filling up a great portion of the body, and subdividing into various branches. Their false ribs, too, like those of the cameleon, encompass the abdomen, and so unite as to form entire circles. The marbled lizard (*Lac. marmorata*, Linn.) may be named as an example. It is of a reddish-gray colour, marbled with transverse irregular bands of brownish red, sometimes mingled with blue. The tail is of great length. This species is frequent in Guiana.

The genus *ANOLIS*, Cuv. combines with the form of the preceding a very peculiar and distinctive character, the skin of the toes being enlarged beneath the ante-penultimate joint, into an oval disk, transversely striated on the under surface, which aids the animal in climbing, which it is otherwise enabled well to do by means of its crooked claws. The body and tail are moreover chagrined with minute scales, and the majority bear a dewlap or goitre-like expansion beneath the throat, which they not only inflate, but cause to change both in form and colour, in accordance with their various moods of love or anger. Indeed several of the species at least equal the cameleon in their power of assuming frequent and rapid alternations in the colour of their skin. Like these creatures, too, and the genus *Polychrus*, the ribs form entire circles. The species are peculiar to America, and several of them are even naturally of familiar habits, frequenting the vicinity of human habitations.

In some there is a crest upon the tail, supported by the spiny processes of the vertebræ, as in *Istiurus* and *Basiliscus*. Such is the great crested Anolis (*An. velifer*, Cuv.), which measures about a foot in length. The crest extends over one half of the tail, and is supported by from twelve to fifteen rays; the dewlap reaches to beneath the belly. (See Plate III., fig. 2.) It is found in the Antilles.

In others the tail is round, or only slightly compressed. The species of this section of the genus are numerous, and have been frequently confounded under one or two specific names. They inhabit the warmer parts of con-

¹ Griffith's Animal Kingdom, ix. 225.

Sauria.
Geckotidæ. tinent America and the West Indies, and change colour with surprising facility, especially in warm weather. They feed on insects, and scarcely equal the size of the gray lizard of Europe. They capture their prey with great alacrity; and the different individuals are said to fight fiercely when they meet each other. We may mention as an example the red-throat lizard, called by Catesby the green lizard of Jamaica (*L. bullaris*, Linn.). Its muzzle is short, speckled with brown, the eyelids projecting, and the prevailing colour a grassy green. It is common in Jamaica, where it frequents hedges and trees, but does not enter houses. When approached or angered it protrudes its gular pouch, which speedily becomes as bright as a cherry. This peculiar change may be regarded as a kind of menace, to deter its enemy from closer quarters. It is incapable of inflicting the slightest injury by its bite or otherwise. Another species is Catesby's green Carolina lizard (*An. Carolinensis*), which is of a beautiful golden green, the muzzle flat and elongated. This kind is said by Catesby to be very common in Carolina, where it frequents houses, and becomes in a manner familiar, so as to sport about tables and windows, catching flies with great dexterity. It is seen chiefly in summer, retreating in winter into hollow trees, where it assumes the torpid state. Sometimes, when tempted by delusive sunshine, it re-appears, and on the return of chilly weather becomes enfeebled by the cold and dies. Its colour changes frequently from green to brown, according to the temperature.

FAMILY IV.—GECKOTIDÆ.

This family consists of what may be termed the nocturnal lizards, all of which bear a strong resemblance to each other. Baron Cuvier regards them as constituting a single genus, divisible according to the form and structure of the toes, as after mentioned.

The genus *GECKO* may be characterized as consisting of Saurian reptiles, of not so lank a form as those of the preceding genera. They are rather of a flattened shape, especially about the head; the feet are of medium size, and the toes of nearly equal length. Their gait is heavy and crawling. Their eyes are large, and the pupil extremely contractile under the influence of light, so that they usually keep themselves concealed throughout the day in dark or sombre places. Their eyelids are very short, and withdraw entirely between the eye and the orbit, which bestows on these animals a very peculiar physiognomy. Their tongue is fleshy, not extensible; the jaws are furnished all around with a row of very small close-set teeth; the palate is toothless. The skin is chagrined above with very small granular scales, among which some larger tubercles are often dispersed; the under parts are covered by flatish scales scarcely so small, and imbricated. The pores on the thigh are not here regarded as a generic character, being absent in some and present in others. The tail is marked by circular folds, as in the genus *Anolis*; but when mutilated, it has been noticed to renew itself without these

Sauria.
Geckotidæ. folds. This genus is numerous and widely spread, occurring both in the old world and the new.¹ The dull and doleful aspect of the geckoes, and a certain resemblance which they bear to toads and newts, render them liable to the imputation of poisonous properties,—an assumption without proof, and altogether against analogy.

The majority of the species have the toes enlarged for a greater or less extent, and furnished beneath with regular folds upon the skin, which, by some peculiar action, enable them to adhere to smooth surfaces, to ascend perpendicular walls, and even to creep in a reversed position along a ceiling. The claws are retractile in different ways, and preserve their points and cutting edges; and these characters, combined with the contractile nature of the pupil, has induced a comparison of the geckoes among reptiles to the feline tribes among carnivorous quadrupeds. The claws, however, vary in the different species, and in some are altogether wanting. It is in accordance with the particular structure of the toes in different species that the geckoes have been subdivided into several separate groups, which some authors regard as constituting so many distinct genera.²

SECT. I.—PLATYDACTYLI. Toes widened throughout, and furnished beneath with transverse scales.

In certain species of this section of the genus the nails are entirely wanting, and the thumb is very small. They are rather ornamental in their aspect, covered over by tubercles, and adorned by lively colours. They occur in the Isle of France. Some have no pores upon the thighs: such are *G. inunguis*, Cuv., of a violet colour above, white beneath, with a black line along the sides; and *G. ocellatus*, Opperl, of a gray hue, covered with brown spots, with white centres. Some possess the pores, as *G. Cepediensis*, a yellowish-red coloured species, marbled with blue, and marked with white along the sides.

In other platydaetylous geckoes the nails are wanting only on the thumbs, and on the second and fifth toes of all the feet, and there are no pores upon the thighs. To this little group belongs the wall-gecko, a European species (*G. fascicularis*, Daud.), called *Terrentola* by the Italians. It is of a deep-gray colour, with a rough head; all the upper parts beset with tubercles, each of which is formed of three or four others of smaller size. It is a creature of a most unseemly aspect, which hides itself in the holes of walls, or beneath heaps of stones, and moreover covers its body with dust and ordure. It, however, delights also in sunshine, and is said not to occur in damp or very sombre situations. In winter it lies inert, but not torpid. It inhabits the countries around the Mediterranean, and ventures as far north as Provence and Languedoc. A nearly allied species occurs in Egypt and Barbary,—*G. Ægyptiacus*, Cuv. Its tubercles are round and simple, more projecting on the sides.

The greater number of the platydaetylous species want the nails only on the four thumbs, and have a range of pores anterior to the anus. *G. guttatus*, Daud. has a reddish coloured body, spotted with white, and beset by round-

¹ The following table exhibits a view of the geographical distribution of the *Geckotidæ*, so far as known at this time:

² See *Erpétologie Générale*, iii. 290.

Sauria.
Geckotidae

ed slightly projecting tubercles. The scales on the under part of the tail are square and imbricated. Seba describes this as a Ceylonese species, and adds, that the name of *gecko* is applied to it on account of its cry resembling that word. It is believed to occur throughout the Indian Archipelago. A belief prevails in the native country of this and other species, that an acrimonious fluid exudes from the lamellæ of the feet, and remaining on fruit, or other edible vegetation, is productive of injury to those who swallow it. A species is described by Bontius in his history of Java, under the name of Indian Salamander; and that old author states that the Javanese are said to hold it up by the tail until it discharges a foam or sanies from the mouth, with which they poison their arrows.

SECT. 2.—HEMYDACTYLI. Base of the toes furnished with an oval disk, formed beneath by a double row of scales *en chevron*; from the centre of this disk the second joint springs, and bears the third or nail at its extremity.

All the known species of the hemydactylous division have five nails on each foot, and a range of pores on each side of the anus. The scales beneath the tail are in the form of broad bands, like those of many serpents. A grayish red kind (*G. verruculatus*, Cuv.) occurs in the southern countries of Europe. The body is beset with small, conical, slightly rounded tubercles, and circles of the same surround the tail. A nearly allied species (*G. mabua*, Cuv.) is widely spread over the warmer parts of the new world, where it often enters dwelling-houses, occurring apparently identical both in Bengal and Pondicherry. Cuvier presumes it may have been transported thither accidentally in ships. A species more peculiar to India is *G. marginatus*, Cuv. of which the body is margined, and the tail flattened horizontally, with its edges sharp and slightly fringed.

SECT. 3.—THECACTYLI. Toes enlarged throughout their entire length, and furnished with transverse scales, which are divided by a deep longitudinal furrow, wherein the claw may lie entirely concealed.

Such as are clearly known do not want the claws except upon the thumbs. They have no pores upon the thighs, and the scales upon the tail are small. As an example, may be named the smooth, or, as it is sometimes called, the perfoliated gecko (*G. lævis*, Daud., *Stellio perfoliatus*, Schneid.). The tail of this species in the natural or normal state is long, and surrounded by the usual fold; but it is easily fractured, and the reproduced portion often assumes a bulbous form, with a tapering termination, not unlike a small turnip with its root. In this accidental condition it was formerly described as a distinct species, under the title of *Lacerta rapicauda*.

SECT. 4.—PTYODACTYLI. Toes dilated only at the tips, and striated below. The dilatation is cleft, and the nail placed in the fissure. The whole of the toes are furnished with curved claws.

In some the toes are free, and the tail rounded. Such is *G. lobatus*, Geoff., sometimes named the house-gecko. It is smooth, or at least both scales and tubercles are very small, the general colour reddish-gray speckled with brown. This species is common in houses in many of the countries on the southern and eastern parts of the Mediterranean. It is known in Cairo by the unlovely name of *about burs*, or *father of the leprosy*, because it is supposed to produce that dreadful malady by poisoning provisions with its feet. Hasselquist relates that he saw at Cairo two women and a girl at the point of death, in consequence of their having eaten

some cheese over which this creature chanced to crawl. He likewise mentions a man who, having laid hold of a *Sauria*.
Geckotidae. gecko, his hand became instantaneously covered with red inflamed pustules, which were as itchy as those produced by the stinging of a nettle. Cats are said to eat these reptiles; and they are driven from the Egyptian kitchens by the odour of garlic. The house-gecko feeds on insects, and its eggs are equal in size to a small nut. Its voice resembles that of a frog.

In others the tail is bordered on both sides by a membrane, and the feet are semi-palmated. Baron Cuvier is of opinion that they are probably aquatic. The species are truly singular in their external aspect. Such is the fimbriated gecko (*G. fimbriatus*, Cuv.), of which the form is much depressed, and the tail bordered by a lateral margin, which is also visible on the sides of the body, where, however, it becomes fringed or slashed. It is a native of Madagascar, where it is erroneously held in great dread. In Lacépède's opinion, it connects together the cameleons, geckoes, and water-newts. It measures eight or nine inches in length; and lives in trees, leaping from branch to branch. The colours of this species, like those of the cameleon, are very changeable, at least on the upper surface, the under portion being usually of a bright yellow. "These changes," says Dr Shaw, "we are informed, have been observed in the living animal by Mons. Bruyeres in its native country, viz. Madagascar, where it is not very uncommon, and where, though a harmless animal, it is held in great abhorrence by the natives, who consider it of a poisonous nature, and fly from it with precipitation, pretending that it darts on their breast, and adheres with such force by its fringed membrane, that it cannot be separated from the skin without the assistance of a razor. The principal cause of this popular dread of the animal is its habit of running open mouthed towards the spectator, instead of attempting to escape when discovered. Its chief residence is on the branches of trees, where it lives on insects, holding itself secure by coiling its tail, short as it is, half round the twig on which it sits. It chiefly appears in rainy weather, when it moves with considerable agility, often springing from bough to bough. On the ground it walks but slowly, the fore-legs being shorter than the hinder."¹

An equally singular species of this section is the scolloped gecko (*G. caudiverbera*), which has no fringe upon the body, but a very peculiarly indented margination on each side of the tail. It is of a blackish colour, measures above a foot in length, and was found by M. Feuillé in a fountain of the Cordilleras. Some confusion exists in systematic works between this species and that figured by Seba under the name of *Salamandra aquatica ex Arabia*.

SECT. 5.—SPHERIODACTYLI. Toes terminated by a small cushion without folds; the claws retractile.

Such species as have the cushion double or notched in front are natives of the Cape of Good Hope and the East Indies. Example, *G. porphyrius*, Daud. More frequently the cushion is rounded and simple, as in the species called the spitting gecko (*G. sputator*, Lac.), a small reptile, pleasingly marked by transverse bands of brown upon a reddish ground. It inhabits houses in St Domingo. A lizard described by Sparman under the same specific name, if not identical with the species just named, no doubt pertains to this genus. It is said when disturbed by a near approach to eject from its mouth a black and acrimonious fluid into the face of the spectator, causing an inflammation of the skin, which, however, is allayed by rubbing the part affected with camphorated spirits of wine.

Finally, there are Saurians which, with all the characters

Sauria.
Chamæ-
leonidæ.

of the geckoes, exhibit no enlargement of the toes, although their claws, five in number, are nevertheless retractile. They at present compose three genera, as follows:

In *STENODACTYLUS* the tail is round, the toes striated beneath, and dentated on the edges. *Sten. guttatus* is an Egyptian species, of a gray colour, sprinkled with whitish spots; the skin smooth. In *GYMNODACTYLUS*, Spix, the toes are slender and bare, and the tail rounded. Example, *Gym. geckoides*, Spix. In *PHYLURUS*, Cuv., the toes resemble those of the preceding; but the tail is flattened horizontally, and shaped like a leaf. The only known species is *Ph. platyura*, from New South Wales, described by White under the name of broad-tailed lizard.¹ It measures about six inches in length, and is of a brownish-gray colour, beset with tubercles. (See Plate III., fig. 3)

FAMILY V.—CHAMÆLEONIDÆ. CAMELEONS.

This family consists solely of the genus *CHAMÆLEO*, distinguished by the following characters. The entire surface is chagrined with small granular scales, the body is compressed, the dorsal edge narrow; the tail is rounded and prehensile. There are five toes on each foot, arranged as it were in two groups, three in one, and two in the other, in some measure resembling the foot of a scansorial bird; but the toes of each group are connate, or enclosed within the skin, as far as the claws. The tongue is fleshy, cylindrical, extensible, and of great length. The teeth are trilobed. The eyes are large in themselves, but almost entirely covered over by the skin, except a small opening opposite the pupil; and each eye has the power of movement independent of the other. There are no external ears, and the occiput rises in a pyramidal form. The first ribs unite with the sternum, and the succeeding ones meet each other so as to form a circle around the abdomen. The lungs are of vast extent, and according to their state of collapse or inflation, greatly affect the form and aspect of the animal. This, with its long power of abstinence, may have given rise to the common belief that it feeds on air.²

Cameleons are insectivorous reptiles, of which the slow pace, the extraordinary form, the awkward movements, the vivacity of eye, and the marvellous rapidity of tongue, have excited the wonder of mankind from the earliest ages. Their change of colour, by no means so marked or sudden as supposed, has nothing to do with the hue of the objects by which they are surrounded, but bears relation physically to the degree of light or obscurity to which they are exposed, morally to the state of their own feelings of fear or anger, and physiologically and directly to the action of the lungs upon the circulating system. "En effet," says Cuvier, "leur poumon les rend plus ou moins transparents, contraignent plus ou moins le sang à refluer vers la peau, colore même ce fluide plus ou moins vivement, selon qu'il se remplit ou se vide d'air." "The general or usual colour in the chameleon," says Dr Shaw, "so far as I have been able to ascertain from my own observation of such as have been brought into this country in a living state, are from a bluish-ash colour (its natural tinge) to a green and sometimes yellowish colour, spotted unequally with red. If the animal be exposed to a full sunshine, the unilluminated side gene-

rally appears, within the space of some minutes, of a pale yellow, with large rounded patches or spots of red brown. On reversing the situation of the animal the same change takes place in an opposite direction, the side which was before in the shade now becoming either brown or ash colour, while the other side becomes yellow and red; but these changes are subject to much variety, both as to intensity of colours and disposition of spots."³

Authors of all ages have differed greatly in opinion regarding the causes of the change of colour in cameleons. The phenomenon, though remarkable, and strongly exemplified in these creatures, is by no means peculiar to them, but occurs, as we have noted in the course of this article, among many others of the reptile race, especially in such as, the general envelope not adhering closely to the muscles, receive a portion of air beneath the skin. It is also observable in many mollusca, particularly the cuttle-fish tribe. But to recur to the chameleon. Aristotle and many other authors have maintained that the change of colour only took place when the animal inflated itself. Pliny repeats the opinion (which has since prevailed) that it assumed the colours of the bodies by which it was surrounded, with the exception of red and white. Wormius was among the first to maintain that the changes in question were due to the emotions of the reptile. Solinus assigns as the cause the reflexion of the luminous rays. Kircher supports the theory of volition and emotion. Goddard adopts the same explanation, with the addition that the colours at the same time bear a relation to neighbouring bodies. Hasselquist and Linnæus refer to the pigmentum as the cause. Finally, the majority of modern authors who have written on the subject (and their name is legion) have sought to explain the phenomenon either by the modifications of the respiratory system, by these modifications combined with the state of the pulmonary circulation, or by the transposition of the various layers which are believed to exist in the pigmentum.⁴

We may state briefly in regard to the geographical distribution of the cameleons, that Africa is their characteristic country. Of the fourteen species known to naturalists, the whole occur there or in the adjacent islands, especially Madagascar; three species, however, are not exclusively African, *Cham. dilepis*, Leach, being found in Georgia, *Cham. vulgaris* in the south of Europe, and *Cham. bifidus* in continental India, the Moluccas, Isle of France, and New Holland. They are thus entirely unknown in America.

These reptiles dwell habitually among shrubs or trees. "Nous avons observé," says M. Bory de St Vincent, "des caméléons en liberté, fixés sur les rameaux des arbustes, qu'ils tenaient fortement serrés entre leur doigts, à peu près comme le font les perroquets dont le pied présente une certaine analogie avec les leurs; ils étaient aussi immobiles que s'ils eussent été des imitations artificielles. Leurs yeux seulement, dont la prunelle brillait comme une pierre précieuse au milieu d'une globe blanchâtre percé d'un petit trou étincelant, roulaient en tout sens, et tandis que l'un regardait par devant, l'autre observait les objets situés en arrière. Quelquefois le mouvement anguleux d'une patte comme disloquée, lentement suivi de celui de la suivante et du déroulement de la queue, qui servait de cinquième point d'appui au caméléon, déterminait un tardif avancement de quelques lignes. Dans cet état de paix, au milieu du feuil-

² "All which considered," says Sir Thomas Brown, in his *Vulgar Errors*, "severer heads will be apt enough to conceive the vulgar opinion of this animal to be not much unlike that of the *Aspidochelone*, or men without mouths, in Pliny; suitable unto the relation of the mares in Spain, and their subventaneous conceptions from the western wind; and in some way more unreasonable than the figment of *Rabican*, the famous horse in *Ariosto*, which, being conceived by flame and wind, never tasted grass, or fed on any grosser provender than air; for this way of nutrition was answerable unto the principles of his generation; which being not airy, but gross and seminal in the *chameleon*, unto its conservation there is required a solid pasture, and a food congenerous unto the principles of its nature."

Chamaeleonidae.

lage des lentilles, sa couleur était d'un blanc assez pur, tirant sur le jaunâtre. Saisi, il se gonflait d'abord et ne faisait nul effort pour éviter le danger; sans doute il en sentait l'inutilité; mais bientôt on voyait circuler sur toutes les parties de son corps des teintes diverses dues au sang, poussé vers la peau par la dilatation de ses vastes poumons. Le caméléon, rendu à lui-même, ne tardait point à reprendre sa couleur blanchâtre que la mort rembrunit. Du reste, le plus innocent de tous les animaux, ce caméléon changeant, qui ne cherche jamais à mordre, vit de mouches qu'il guette; lorsque celles-ci passent à sa portée, son corps, sa tête, ses membres demeurent immobiles; mais il a calculé la portée de sa langue, il la lance comme un trait; et l'animal ailé, malgré son agilité et la promptitude de son vol, se trouve collé au bouton visqueux qui le rapporte en un clin d'œil dans la bouche de son ennemi.

"On a imprimé, dans la plupart des livres d'histoire naturelle, qu'on ne trouvait des caméléons que dans les parties les plus chaudes des régions intertropicales. Ces animaux s'y plaisent sans doute, mais non seulement ils dépassent les tropiques, ils s'élèvent encore beaucoup au nord dans la zone tempérée, puisque nous en avons trouvé fréquemment dans le midi de l'Espagne. L'espèce de Barbarie y est aussi commune autour de la baie de Cadix, où lorsque, pour les opérations de la siège, nous faisons abattre des pins sur la rive gauche du Guadalquivir, nous en trouvons communément entre les rameaux dont se formaient la cime de ces arbres. On en voit dans quelques maisons, qui demeurent fort longtemps, sans remuer, suspendus à des ficelles sur lesquelles on les a placés comme objets de curiosité; les chats en sont assez friands, et ceux qu'on tient en captivité finissent ordinairement par les griffes de ces tigres domestiques."¹

The best-known species is *Cham. vulgaris*, often called the Africanameleon (*Lac. Africana*, Gm.), an ill-selected name, in as far as several other kinds occur in Africa, and the species in question spreads from the south of Spain through many intermediate countries into India. The hood is pointed, and raised into a ridge on its anterior portion, the dorsal ridge is dentated as far as the middle of the back, the inferior one as far as the anus. The granules of the skin are equal and closely set. In the female the hood is of smaller size, and the dentations of the ridge less strongly marked. It is to this species, which measures about a foot and a half in length, that our preceding quotations apply, and that is also referred to in most of the general observations on cameleons found in books. (See Plate III., fig. 1.)

The female deposits her eggs to the number of thirty, in an excavation which she hollows in the ground, and afterwards covers over with loose earth, "servendosi," says Valisnieri, "a questo lavoro delle sole zampe di dietro, come i gatti, quando nascondono et cuoprono le loro sozzure, non contenta della cavata terra vi ramassò e ammonticello delle foglie secche, della paglia, e degli stecchetti avendovi inalzato sopra una collinetta di copertura."²

We shall here mention briefly a few of the most distinctly known of the other species of the genus.³ *Cham. tigris*, Cuv., has the hood or helmet small, and is distinguished by a compressed dentated wattle beneath the end of the lower jaw. Its body is beset with black points, and the granules are fine and equal. It inhabits the Seychelle Islands. An allied species (*Cham. verrucosus*, Cuv.) has larger granules mingled with the others, and there is a series of parallel warts on the sides of the back. It is a native of the Mauritius. *Cham. pumilus*, Daud., has the hood directed backwards, and scattered warts upon the sides, limbs, and tail; and beneath the throat are numerous compressed finely-

toothed wattles, which vary in different individuals. It occurs in the south of Africa, the Isle of France, and the Seychelles. Cuvier is of opinion, that *Cham. Serchellensis* of Khul is merely the female of this species. The Senegal kind, *Cham. planiceps*, Merr. (*Lac. chameleon*, Gm.), has the hood flattened, almost without ridge, and horizontally of a parabolic form. It occurs in Bahary, and has likewise been seen in Georgia. *Cham. pardalis*, Cuv., from the Isle of France, is marked irregularly with black round spots, bordered with white. A peculiar species from the Moluccas is distinguished by two large compressed prominences projecting in front of the muzzle. It is the *Cham. bifurcus* of M. Brogniart.

Sauria.
Scincidae.

FAMILY VI.—SCINCIDÆ.

Distinguishable by their short legs, their unextensible tongue, and their scales of equal size, which cover the body and tail like tiles.

In the genus *SCINCUS*, Daud., the legs are rather short, the body of almost equal size with the tail, without any occipital enlargement, crest, or dewlap, the scales uniform, shining, and disposed like those of a carp. Some of the species assume a fusiform or spindle shape, others are nearly cylindrical, and more or less lengthened, resembling certain Ophidians, especially those of the genus *Anguis*, with which they are likewise connected by several internal relations. The tongue is fleshy, little extensible, and but slightly cleft; and the jaws are furnished all around with small close-set teeth. The toes are free.

A few have teeth upon the palate. Of these is the common or officinal scink (*Sc. officinalis*, Schn., *Lac. scincus*, Linn.), which measures six or eight inches in length. The tail is shorter than the body, and the proportional length considerable from the snout to the shoulder. The general colour is a silvery yellow hue, with transverse blackish bands. It is very abundant in Libya, Syria, Arabia, and Egypt, and is frequently imported from Alexandria into Europe. It frequents rather dry and sandy soils, and is remarkable for the extraordinary rapidity with which it burrows, vanishing almost instantaneously, and seeming, as Bruce has well expressed it, "rather to have found a hole than to have made one." This is the reptile called *el adda* by the Arabs. It was once held in high estimation as an article in the *Materia Medica*, its flesh being regarded as advantageous in leprosy and many other cases. A much larger species (*Sc. Cyprus*) occurs in the Levant, and some of the Mediterranean Islands, *Sc. rufescens* is widely spread over India, and *Sc. trivittatus* is common at the Cape of Good Hope. To this group also belongs the galley-wasp of Jamaica (*Sc. occidua*, Shaw), a large reptile of nearly two feet in length. We are not acquainted with its modern history, and it possesses no poison apparatus, though Browne in his *Natural History of Jamaica*, informs us that it is reckoned the most venomous reptile in the island, and that it is believed no creature can recover from its bite. The author, however, justly regards this as a popular error.

Other species of this genus have no teeth upon the palate. Such is *Sc. ocellatus*, Schneid., well known in the southern countries of Europe, the Mediterranean Islands, Egypt, &c. The West Indies, the Moluccas, and New Holland, produce analogous kinds, some of them remarkable for their size.

The genus *SERS* of Daudin differs from the preceding in having the body so elongated as to resemble that of a serpent (a conformation well expressed by the names *Lacerta*

¹ *Diction. Class. d'Hist. Nat.*, iii. 96.

Sauria.
Scincidæ.

Serpens, *Anguis quadrupes*, &c., which certain species bore); their legs are extremely small, and the two pairs placed at a great distance from each other. (See Plate III., fig. 4.) The lungs in this genus begin to exhibit an inequality of size. Indeed, we may here observe that in the few remaining groups of Saurian reptiles with which we are still to be engaged, there is a manifest approximation to the true serpents or Ophidian race, in the diminution of the feet, the entire disappearance, in certain species, of either the anterior or posterior pair, and the elongated form of the body. Indeed, on the one hand, *Lacerta apoda* of Pallas is actually now classed with the Ophidians (being placed at their head), although on each side of the anus there is a prominence containing a small bone analogous to the femur, and pertaining to a true pelvis concealed beneath the skin; while on the other, certain systematic writers range our *Anguis fragilis*, and other snakes usually so called, among the Saurian reptiles. But to return to our remaining genera, which may really be said to hold their legs and feet by a precarious tenure, so subject are they to variation—the five-toed seps (*S. pentadactylus*, *Lac. serpens*, Linn.) inhabits the East Indies, while a four-toed species (*S. tetradactylus*), and a third with only three toes (*S. tridactylus*), both being viviparous, occur in the Isle de Crès. Another three-toed species (*S. chalcides*) is native to the south of Europe, and is named *cecilla* by the Italians. It dwells in meadows, feeding on spiders, slugs, &c., and runs rapidly by means of a snake-like wriggling motion, without using its feet. It is also viviparous. A more peculiar kind, known under the name of serpent-lizard (*S. monodactylus*, *Lac. anguina*, Linn.), occurs at the Cape of Good Hope. Its legs are nothing more than small footless undivided appendages. This is the *vermis serpentiniformis ex Africa* of Seba, said by some authors to be found “in great plenty in the water and about the rocks in Table Bay.”

The genus *BIPES*, Lacép., makes a still nearer approach to the serpents, as its name indicates. It scarcely differs from *Seps*, except in the entire absence of the fore-legs. It forms, as it were, the stepping-stone to *Anguis*. (See Plate III., fig. 5.) A species from New Holland (*B. lepidopoda*, Lacép.), examined by Baron Cuvier, although its hinder extremities showed themselves externally only under the form of a pair of small oblong scaly plates, was yet found on dissection to possess a femur, tibia, peroneum, and four metatarsal bones without phalanges. To this genus likewise belongs an African species, the *Anguis bipes*, Linn., and another of larger size from Brazil, described by Spix under the name of *Pygopus cariococca*.

The genus called *CHALCIDES* by Daudin is likewise characterized by a long and serpent-like body, but there are four legs (as in *Seps*), and the scales, instead of overlapping like tiles, are rectangular, and form transverse bands, which do not encroach upon each other. (See Plate III., fig. 6.)

Certain species have a groove on each side of the body, and the tympanum still very obvious. Of these, an East Indian kind (*Chal. seps*, *Lac. seps*, Linn.) has five toes, while another (*Chal. tetradactylus*) has only four. Others have the tympanum concealed, and conduct directly to *Chirotes*, and through it to the ophidian genus *Amphisbæna*. Examples, *Chal. pentadactylus*, which, as its name implies, is a five-toed species, and *Chal. heterodactylus* (*Het. imbricatus*, Spix), which has four toes to the front feet and five to the hinder. *Chal. abdominalis*, Thunberg, has four toes on each foot. Lastly, *Chal. flavescens*, Gray (*Chal.*

monodactylus, Daudin), is distinguished by five anterior and three posterior toes, so reduced in size as to resemble small tubercles, and so ill defined by nature (to our perceptions, though no doubt wisely formed in relation to the end in view), that zoologists still differ as to their exact amount. The species alluded to is native to Guiana.

The genus *CHIROTES*, Cuv., resembles *Chalcides* in its verticillated scales, and is allied to *Amphisbæna* by the blunted form of its head; but it is distinguished from the former by the absence of the hind legs, and from the latter by the presence of the fore ones. (See Plate III., fig. 7.) The only known species is the lumbriciform lizard of Shaw (*Chir. lumbricoides*,—*canaliculatus* of Lac.), a native of Mexico, and first described by Lacépède. It has two short anterior feet (each with four toes, and the rudiments of a fifth), well organized interiorly, and attached to a small sternum by means of shoulder-blades and clavicles; but the head, vertebræ, and the general skeleton closely resemble those of the genus *Amphisbæna*. It is of a flesh colour, and measures eight or ten inches long, with a circumference like that of the little finger. It is surrounded by about 220 semi-rings upon the back, and as many on the abdomen, which meet upon the sides in alternation. The tongue of this species is but slightly extensile, and terminates in two little horny points. Its eye is extremely small, and the tympanum invisible outwardly, being covered by the skin. On dissection, Baron Cuvier could detect in this reptile only a single large lung, with the vestige of a small one, as in serpents. It preys on insects.

ORDER III.—OPHIDIA, OR SERPENT-SHAPED REPTILES.

The exact lines of demarcation which separate the primary orders of the reptile race are somewhat difficult to draw, as in truth must always be the case wherever there are strong affinities of form and habits. *Natura non facit saltum* is a saying the truth of which the student of her manifold wonders must ever remember; and in our present department especially there are several very singular creatures, which so combine the characters of two contiguous orders that well-instructed naturalists differ as to whether they should terminate the one or commence the other. Thus Baron Cuvier's last Ophidian genus is *Cæcilia*, which Professor Bell regards as a Batrachian reptile, or rather as belonging to his separate class AMPHIBIA, which, after the example of Blainville and Latreille, he constitutes by means of the entire Batrachian order.¹ Thus also *Lacerta apoda* of Pallas, though furnished on each side with a small bone analogous to the femur, and pertaining to an actual pelvis concealed beneath the skin, is yet classed by the great French anatomist with the Ophidians, being, so to say, the “very head and front of their offending;” while several systematic writers range our *Anguis fragilis*, and other snakes commonly so called, among the lizards. An American reptile, *Anguis ventralis* of Linn., now forms Daudin's genus *Ophisaurus*, the name of which (derived from *ὄφis*, *serpent*, and *σαυρος*, *lizard*) implies the peculiar combination now referred to. The Saurian genus *Seps*, described at the conclusion of our former order, is characterized by Cuvier as having an elongated body, “tout-à-fait semblable à celui d'un orvet” (*Anguis*); and, on the other hand, the same author enters upon his Ophidian order by means of the *Anguidæ*, or slow-worms, which he simply describes as “des seps sans pieds.” These, and other

Ophidian
Reptiles.

¹ *Encyclopædia of Anatomy and Physiology*, part i. p. 91. These amphibian orders are as follows:—1st, *Amphipneusta*, containing the Sirens and Proteans; 2d, *Anoura*, the frogs and toads; 3d, *Urodela*, the salamanders; 4th, *Abranchia*, the genera *Menopoma* and *Amphiuma*; and 5th, *Apoda*, the genus *Cæcilia*. “It is easy,” adds Mr Swainson, “to perceive that this last passes into the first by means of the dipod Sirens, and thus the whole form a circular group more or less perfect in its connecting links.” (*Cabinet Cyclopædia*, vol. cxvi. p. 86.)

² See *Règne Animal*, ii. 69.

Ophidian Reptiles. examples which it would be easy to adduce, demonstrate the close connection which subsists between the Saurian and Ophidian orders.

It has indeed been customary to class among serpents whatever reptiles combined the absence of limbs with an extremely lengthened form of body; but a more rigorous observation will demonstrate that several species which, in accordance with that principle, will take their place as serpents, are yet in their prevailing organic structure removed from them in most essential points, the chief resemblance being that of the external and extremely lengthened form. Now this attenuated aspect, and absence of all the ordinary locomotive members, are likewise exhibited by several Saurian reptiles, and of course in an increased degree as they actually approach the serpent or Ophidian tribes; but the two characters just mentioned do not convert them from one order to another, being still held as it were in subordination to the general structure.¹

We commence our description of OPHIDIANS with the animals that have the general form of *serpents*; but yet differ from them anatomically so much that they cannot be considered as true SERPENTS; and have been judiciously separated from them by M. Schlegel. We divide Ophidians into the groups CÆCILIA, AMPHISBÆNA, ANGUIS, and SERPENS.

CÆCILIDÆ, OR BLIND WORMS.

The character of this group is fully given in the description of the only genus.

Genus CÆCILIA. Eyes extremely small, almost concealed beneath the skin, sometimes wanting. Skin smooth, viscous, furrowed by annular folds, apparently naked, but exhibiting in its thickness certain slender scales, regularly disposed on many transverse ridges between the wrinkles of the skin. Head depressed, anus nearly terminal, tail consequently short or almost wanting. Ribs too short to surround the trunk. Vertebrae articulated by facets like hollowed cones filled with gelatinous cartilage, as in fishes and some Batrachia; the cranium united to the first vertebra by two tubercles, also as in Batrachian reptiles. The orbits, covered by the maxillary bones, are only pierced by a very small hole; and the bones of the temples cover the temporal fossæ in such a way that the head exhibits superiorly nothing but a continuous bony buckler. (See Plate IV., fig. 1 d.) The hyoid bone, composed of three pair of arches, is so constructed as almost to lead to the belief that in early age there were gills. The maxillary and palatine teeth are ranged on two concentric lines, as in the genus *Proteus*, but are frequently sharp and curved backwards, as in true serpents. The nostrils open at the back part of the palate, and the lower jaw has no moveable pedicle, the tympanic bone being encased with the other bones in the buckler of the cranium. The auricle of the heart is not sufficiently divided to be described as double; but the second lung is rudimentary, as among the genuine Ophidians. The liver is divided into many transverse foliations.

We know nothing of the natural history or habits of the animals of this genus. They are said to dwell in marshy ground, several feet below the surface. They probably prey on worms and insects, although vegetable matters, mould, and sand, have been found in their intestines.

In certain species the muzzle is obtuse, the skin loose, the folds conspicuous, and there are two small hairs near the nostrils. To this section belongs *Cæc. annulata* of Spix, a Brazilian species of subterranean habits. It is of a blackish hue, with upwards of eighty annular folds, and circularly marked with white. The teeth are conical. Others have the folds more numerous, or rather in the form of serrated transverse striæ. Such is *Cæc. glutinosa*, Linn., from Ceylon, a blackish-coloured reptile, marked by a longitudinal band of white on either side, and characterized by 350 folds, which unite beneath in an acute angle. We have figured a nearly allied species from America, *Cæc. bivittata* of the French naturalists. (See Plate V., fig. 3.) Finally, a few have the folds almost effaced, the body long and slender, and the muzzle projecting. *Cæc. lumbricoides*, Daudin,² is entirely blind, of a blackish colour, two feet long, and not thicker than a quill. Baron Cuvier possessed the skeleton of a Cæcilia more than six feet long.³ There were 225 vertebrae, but the external characters were unknown.

Ophidian Reptiles.

AMPHISBÆNIDÆ, PROGRESSING EITHER WAY.

The lower jaw still continues, as among the preceding groups, supported by a tympanic bone, articulated directly to the cranium, the two branches of that jaw being soldered together anteriorly, while those of the upper one are fixed to the cranium and the intermaxillary bone. This formation both produces an equality of dimension between the head and the rest of the body, and also prevents that peculiar power of dilatation for which the genuine serpents are so remarkable. (See Plate IV., fig. 1 a.) Their general form, according to Cuvier, "leur permet de marcher également bien dans les deux sens," a fact, however, which that great observer does not seem to state as from the "ocular proof," and for the confirmation of which we have sought in vain in the work of any well-instructed traveller. The bony frame-work of the orbit is incomplete behind, the eye is extremely small, and the body is covered with circular plates. The windpipe is elongated, the heart placed far backwards, and the anus situate close to the extremity of the body. None of the known species is venomous. Of the two genera, the one is closely related to *Chalcis* and *Chirotis*, the other to *Anguis* and *Acontias*.

Genus AMPHISBÆNA, Linn. The entire body covered by circular ranges of plates. A range of pores anterior to the anus. Teeth of a conical form, numerous on the jaws, none upon the palate; only a single lung.

The species are South American reptiles, to which an ancient classical name has been with no great propriety applied. (See Plate IV., fig. 2.) The white one, *Amph. alba*, Linn., measures from a foot and a half to two feet in length, and is proportionably of a bulky form.⁴ It inhabits Brazil, where its native name of *Ibriaram* signifies "lord of the earth." It was first described by Marcgrave, who, however, states erroneously that it is venomous, and will wound either with head or tail. It preys on insects, and is often found near ant-hills. Another species, from Martinique (*Amph. cæca*, Cuv.), is stone-blind.

It may be observed in passing, that the genus *Leposternon* of Spix is composed of *Amphisbænæ*, of which the anterior part of the body is furnished below with several

¹ "Un examen comparatif," observes M. Schlegel, "des objets m'a démontré que ces Sauriens anomaux, c'est-à-dire, à formes allongées et à extrémités rudimentaires, appartiennent toujours par l'ensemble de leur organisation à quelque espèce de l'une ou l'autre des familles de cet ordre, parmi lesquelles ils doivent être distribués. On ne peut nier, par exemple, qu'il y a un passage graduel des Scinques à l'Anguis et aux Acontias, par l'intermède des Scinques brachypus, decrensis, serpens, seps, du Pygodactyle et du Bipes,—êtres moins différens entre eux par leur organisation que par leurs formes, et qui ne composent qu'une seule famille, celle des Scincoides, de laquelle on ne saurait exclure ni les Ablephares ni les Gymnophthalmes. Le même passage graduel existe dans la famille des Lézards, des genres *Lacerta* et *Tachydromus* au *Monodactyle*; on y peut ajouter comme espèce anormale le *Pygopus*. On pourrait rapprocher dans la méthode le *Tetractyle*, le *Chalcis*, le *Pseudopus*, et l'*Ophisaurus*. Viennent enfin la famille des *Amphisbænæ*,—*Chirotes*, *Leposternon*, *Amphisbæna*, et celle des *Typhlops*,—*Typhlops*, *Rhinophis*, *Uropeltis*." (*Physionomie des Serpens*, i. p. 2.)

Ophidian
Reptiles.

plates, which interrupt the ranging of the circular rings. They have no pores anterior to the anus, the head is short, and the muzzle slightly projecting. Example, *Lep. microcephalus*, Spix,—*Amph. punctata* of Prince Maximilian (Neuwied).

Genus *TYPHLOPS*, Schneider. Body covered with small imbricated scales (as in *Anguis*, with which group the species were for a long time combined). Muzzle advanced, furnished with plates. Tongue long and forked; eye in the form of a minute point, scarcely visible through the skin; anus almost terminal; one lung four times larger than the other.

These, as Cuvier remarks, are small serpent-like creatures, which bear a great resemblance to earth-worms. They inhabit the warmer countries both of America and the old world. Some have the head obtuse, and of equal diameter with the body. Such is *T. braminus*, Cuv., the punctulated slow-worm of Shaw, and *Rondos talooloopani* of Dr Russel.¹ It is a diminutive reptile, measuring about six inches in length, with the thickness of a hen's quill. It is of a cream-colour, powdered over with innumerable black dots. It is common in Vizagapatam, and, according to the author last named, is vulgarly reputed mischievous. It is described as moving with great swiftness; and a specimen immersed in spirits remained alive for more than ten minutes. Others (and these the majority) have the muzzle depressed and obtuse, and furnished anteriorly with several plates. Example, *T. reticulatus*.² A few have the front of the muzzle covered by a single broad plate. Such is *T. subargenteus* (*Anguis lumbricalis*, Linn. and Lacép.), the silvery snake of Brown.³ Finally, there are one or more peculiar species, in which the muzzle terminates in a small conical point, and the posterior extremity is enveloped by a horny buckler of an oval form. We here place *T. Philippinus*, Cuv., which measures about eight inches in length, and is entirely of a black colour. We presume that Dr Shaw's snouted slow-worm, *Anguis nasuta* (*A. rostrata* of Weigel⁴), though differing in colour, is nearly allied, and ought to be placed in the same genus.

ANGUIDÆ, OR SLOW-WORMS.

These still exhibit the bony head, the teeth, the tongue of *Seps*, and the eye is furnished with three eyelids. They correspond to the ancient unrestricted genus *ANGUIS* of Linneus, and are characterized externally by imbricated scales covering the whole body. The species now form four minor genera, of which the first three still exhibit beneath the skin certain small bones corresponding to those of the shoulder and pelvis.

Genus *PSEUDOPUS*, Merrem. Tympanum visible externally. A prominence on each side of the anus, containing a small bone analogous to the femur, and appertaining to a true pelvis hid beneath the skin. Rudiments of the anterior extremities barely manifested by an inconspicuous fold, containing no interior humerus. One of the lungs is a quarter less than the other. The scales are thick and imbricated, and between those of the back and belly are some smaller scales, which produce a longitudinal furrow on either side.

Of the species, the earliest known is *P. Pallasii*, Cuv., *Lacerta apoda*, Pallas,—discovered in the south of Russia by the naturalist last named.⁵ It measures from one to

two feet in length, and the colours are ferruginous above, pale yellow beneath. The scales of the back are smooth, those of the tail carinated. This species occurs also in Hungary and Dalmatia, and the specimen figured by Dr Shaw⁶ was procured in Greece by Dr John Sibthorpe, the professor of botany in the university of Oxford. M. Durville discovered another species (which bears his name) in the Archipelago.⁷ (See Plate IV., fig. 1.)

Genus *OPHISAURUS*, Daudin. No external appearance even of the hinder extremities, but the tympanum is still apparent, and the scales exhibit a plication or folding upon each side of the trunk. The smaller lung only equals a third of the greater.⁸

The best known species is *Oph. ventralis*.—*Anguis ventralis*, Linn.,—an American reptile, common in the southern states of the Union. It is of a greenish yellow, spotted above with black. Its tail is longer than its body, and the creature itself is so brittle and easily broken, even in the living state, as to be known by the name of glass serpent. According to Catesby, "a small blow of a stick causes the body to separate, not only at the place struck, but at two or three other places, the muscles being articulated quite through the vertebræ."⁹

Genus *ANGUIS*, Cuv. No extremities visible externally. Tympanum concealed beneath the skin. Maxillary teeth compressed and hooked,—no teeth upon the palate. Body surrounded by imbricated scales, without plication on the sides. One of the lungs is a half less than the other.

The English slow-worm, *Anguis fragilis*, is common over a great part of Europe.¹⁰ It is very smooth, of a shining brownish-gray above, inclining to reddish on the sides, and bluish-black upon the under surface. It rarely measures more than a foot in length. It lives on insects and small mollusca, excavates circuitous holes in the earth, of several feet in extent, and with more than one issue. It is an innocent and gentle creature, remarkable for stiffening itself so much when seized as sometimes to break in two. Hence its specific name of *fragilis*.

Genus *ACONTIAS*, Cuv. No osseous pieces corresponding to the sternum and pelvis, the shoulder-blades and clavicles. Anterior ribs united to each other inferiorly by cartilaginous prolongations. Teeth small and conical: "Je crois," says Cuvier, "leur en avoir aperçu quelques-unes au palais."¹¹ Muzzle inclosed in a kind of mask. One lung of medium size, and another of very small dimensions.

To this genus belongs the speckled slow-worm of Shaw, *Anguis Meleagris*, Linn., a native of the Cape of Good Hope.¹² Its tail is much shorter and more obtuse than that of the British slow-worm. Its upper surface is spotted longitudinally with brown. Africa produces other species, one of which, according to Cuvier (*Ac. cæcus*), is entirely blind.

We now reach Baron Cuvier's second great division, the *OPHIDIANS*, consisting of all those genera which exhibit no vestige of either shoulder or sternum, but have a great portion of the circumference of the body surrounded by the ribs. The vertebræ articulate by means of a convex facette at one end, entering into a concave facette of that which follows. (See Plate V., fig. 2 a and 2 b.) The third eyelid and the tympanum are wanting, but the osselet of

the ear exists beneath the skin, and its handle passes behind the tympanic bone. Several still manifest a remnant of the posterior members hid beneath the skin, or even showing themselves externally under the form of small hooks.¹ The first two genera are scarcely entitled to the designation of *True Serpents*; and Baron Cuvier has himself drawn a line between them and those which he names *Serpents properly so called*, although the two terms seem not particularly distinctive. The reptiles in question form the tribe *Double Marcheurs* of Cuvier.

We now arrive, "by lingering steps and slow," at the genuine serpents.

SERPENTES, OR TRUE SERPENTS.

The principal characteristic of the serpent race consists in an extremely elongated body, clothed with scales, destitute of limbs, and furnished with a tail, or caudal extremity. Locomotion is effected by lateral undulations, aided by the scales externally, and by the ribs within. Although the general form, viewed in relation to its transverse dimensions, is concentrated to an extremely small diameter, the different parts are capable of great enlargement, which admits in many cases of their swallowing bodies bigger than themselves. In conformity with this peculiar structure, even the bony portions of the head are not so knit together as in other animals, but, with the exception of the parts which protect the brain, are capable of a certain degree of separation. (See Plate IV., fig. 1 b.) The development of the tympanic bones, their mode of attachment, the mobility which they enjoy from not being fixed to the cranium by their lower extremity, and finally, the structure of the under jaw, the two branches of which are capable of separation in consequence of being united by elastic ligaments instead of symphysis, all combine to produce the vast swallowing powers of these reptiles. The entire absence of limbs is accompanied by an equal absence of those solid portions, such as the sternum and pelvis, which unite the limbs with the body. The ribs are free for the same reason, and thus readily admit both of the occasional enlargement of the intestinal cavity, and of that extreme pliancy of form for which all the species are remarkable, whether they creep, climb, or swim. To facilitate these various movements, the general envelope is minutely subdivided into numerous compartments, the scales of the lower surface being usually much larger than those of the upper, and subserving the place of feet, the ribs being attached to the lateral margin of the inner surface of these abdominal plates. The space of bare skin between the scales is greater among serpents than other reptiles, and on the throat this bare expanse forms a longitudinal cleft, known by the name of *gular furrow*.

The true serpents are closely connected to the Saurian order by the preceding genera *Amphisbæna* and *Typhlops*, which certainly form a passage from one of those great ordinal groups to the other. It is these connecting links that render precise definitions, drawn from a few apparent characters, so difficult, if not impossible. "Il est très facile," observes M. Schlegel, "de se faire une idée d'un serpent, lorsqu'on prend pour type une des espèces où tous les caractères de l'ordre se trouvent réunis; mais il est difficile de consigner des marques distinctives qui separent d'une manière tranchée les Ophidiens des Sauriens."² Thus the gular furrow which characterizes all serpents except the genus *Acrochordus*, exists also among lizards, and several

Ophidian
Reptiles.

other Saurian reptiles. A few Ophidians even exhibit vestiges of the hinder extremities analogous to what we may observe among the so-called apodal Saurians, although there is reason to suspect that the parts alluded to represent, in the latter the pelvis, in the former the actual extremities.³ Perhaps the characters deduced from the bones of the cranium would afford the best distinctions between the two orders, were it not that in these, too, certain species of the genera *Typhlops* and *Uropeltis* make a near approach to the true Ophidians. It may be well, however, to state briefly the distinguishing features in the cranial osteology of the latter order. The bones of the face in serpents never form a fixed mass perforated by the nostrils, and incased by sutures in each other; and the intermaxillary bone, trigonal, and compressed in its form, is always free, and to a certain extent moveable, that is, never soldered by sutures to the maxillaries on either side. The maxillaries themselves, when united to the anterior frontals, are so merely by a narrow attachment, always preserving a certain mobility; and the lateral margins of the nasal bones are free throughout their whole extent. No Ophidian reptile has thick conical teeth perpendicularly incased; they rather resemble hooks curved backwards, with sharp points; and we believe that all serpents, with the exception of the genus *Oligodon*, have the palate armed with teeth resembling those on the maxillæ, whilst in the Saurian order the palatine teeth exist only in the form of small irregular asperities.

From the preceding brief sketch, it may be inferred that the most peculiar character of serpents consists in their mode of locomotion, and their extraordinary powers of deglutition. These conditions modify their entire organization, for the former determines the general shape of the body, and the latter that of the internal parts. On examining the position of the intestines, we find that these organs, which in the majority of other vertebrated beings occupy several spacious cavities, are in the Ophidians inclosed within a long and narrow cylinder. It is obvious that this disposition cannot prevail without great changes in the form of the viscera; and the disturbance alluded to is even destructive of bilateral symmetry. We thus find the heart sometimes far removed from, at others closely approached towards, the head, according as the stomach is more or less extended; it is thus also that most frequently there is only a single lung, sometimes extending in front of the heart, but usually placed behind that organ, and almost always terminated by a species of sack of greater or less extent, and serving as a reservoir of air. The liver, for the same reason, assumes a narrow ribbon shape, extending from the heart to the pylorus. The gall-vessel, that it may not be interrupted in its functions by the repletion of the stomach, is removed from the liver, and placed in the same curve of the duodenum as that which receives the pancreas and the spleen. The stomach resembles a lengthened narrow cylinder. Then follow the intestines, of which the numerous inflections are filled with fat, and which, after descending in a straight line, terminate in the cloaca. The lower portion of the abdominal cavity not being sufficiently spacious for the reception of the rest of the organs, there thence results an anomalous disposition of the kidneys, testicles, and ovaries. "La verge enfin, et un organe sécréteur, sont logés dans la queue." These peculiar forms, however, of the majority of the internal parts of serpents exercise no influence over their functions; for, on more minute investigation, we find

¹ Naturalists, as we shall afterwards take occasion to notice, differ in their views regarding the exact nature of these outward appendages. They are described by M. Mayer in the twelfth volume of the *Academia Naturæ Curiosorum* of Bonn.

² *Essai sur la Physionomie des Serpens*, par H. Schlegel, La Haye, two vols. 8vo, 1837. Of this the most recent and complete work on our present department with which we are acquainted, we have availed ourselves largely in the following treatise.

³ We have exhibited these parts as they exist in the genus *Boa*. See Plate V., figs. 1, 1 a, and 1 b.

Ophidian
Reptiles.

that they vary not only in distinct species, but in different individuals of the same species.

The disposition of the external organs, on the contrary, present much more constant forms; but these parts are modified by the habits of the species, whether arboreal, terrestrial, or aquatic. The mode of locomotion is, however, very uniform, the movement being nearly the same which aids a serpent while gliding on the surface of the ground, traversing the depths of lakes and rivers, or climbing around the umbrageous branches of forest-trees. The lateral undulations of the body suffice for these progressions; and it is chiefly the sea-snakes that make use of their tails, which are expressly organized for that special purpose, acting as a scull. The degree of rapidity depends in a great measure on the nature of the surface in which the motion is exercised. Serpents drag themselves along with difficulty over glass or any polished body, but make their way with great alacrity over any earthy irregular surface, or through tangled vegetation. For the exercise of these movements, it is of course necessary that the bones and muscles should be fitly disposed; and every one who has examined a properly prepared serpent must have been struck at once by the multiplicity and uniformity of its parts. The ribs and vertebræ are almost all alike in their formation, and it is only towards the caudal extremity that the bones diminish in bulk.

As all the vertebræ of serpents carry two ribs, the usual distinctions of cervical, dorsal, and lumbar do not exist. As the scaly plates or scuta of the abdomen have each two ribs as their levers, their number corresponds to that of the vertebræ, and the ribs are double that of the scuta. This number varies not only with the species, but the individuals, and to so surprising an extent that we not unfrequently find a difference in the same species, amounting to thirty or even fifty vertebræ. The number of vertebræ of the body, properly so called, rarely exceeds 300, and is never fewer than 100; the vertebræ of the tail, on the contrary, are sometimes reduced to five, although in other cases they amount to from 150 to 200. The ribs are more numerous in serpents than in any other class of created beings, several having above 500,—that is 250, or upwards, on each side of the spinal column. We here figure the skeleton of the common ringed snake of England,—*Tropidonotus natrix*. (See Plate V., fig. 2.)

The muscles exhibit various modifications in the different species. In some they are remarkable for their considerable size, and for the extraordinary development of tendons, especially among the venomous kinds. This organization is necessary for the production of that force and energy with which their undulating movements are often executed. The muscles which produce these effects are situate along the sides of the back, and on the anterior face of the vertebræ; but as the ribs likewise exercise the function of locomotive organs, the numerous muscles which are attached to these parts greatly facilitate the lateral movements. The muscles of serpents being greatly interlaced, it becomes difficult to describe them singly, and their comparison with analogous parts in their higher orders is by no means easy. These anatomical details, however, are not to be expected in the present publication. We therefore refer the reader to the works of Home,¹ Hubner,² Dugès,³ Duvernoy,⁴ Meckel,⁵ and Schlegel.⁶

The muscles of serpents, as of other reptiles, preserve their irritability for a long time after what we may regard as the actual death of the animal; for these creatures, although deprived of their head, and divested of their skin, will continue to exhibit muscular movements for several

weeks, if kept in a moist condition. Swammerdam, in his *Biblia Naturæ*, has proved, both by his figures and descriptions of frogs, that even at that early period (1666), peculiar galvanic effect was demonstrated in the muscles of these reptiles which at a future period gave rise to so much important discoveries regarding the phenomena of voltaic electricity.

A few words may be said regarding the supposed vestiges of the hinder extremities observable in certain serpents. Several species exhibit on each side of the anus a small hook or crotchet, half concealed by scales. The existence of these parts has been long recognised, but we believe it is to Professor Mayer of Bonn that we owe a more precise knowledge of their nature. The only Ophidian genera in which they have been hitherto precisely observed are *Tortrix*, *Python*, and *Boa*. They are most developed among the Boas, and the huge size of these reptiles admits of a more satisfactory examination. (See Plate V., figs. 1, 1 a, and 1 b.) These vestiges, then, consist of an assemblage on each side, of three principal osseous pieces, and of two small accessory portions attached at the point of articulation of the tibia and tarsus. The terminal bone, which alone appears externally, is in the form of a crotchet, covered by a hard and scaly skin. When a longitudinal incision is made in the flesh, we find that the interior piece, which is the most developed, more or less S-shaped, and comparable to the tibia, is prolonged with its free extremity into the abdominal cavity. The middle portion, on the contrary, which seems to represent the tarsus, is thick, short, slightly arched, and completely concealed within the flesh. This apparatus is moved by flexor and extensor muscles of a sufficiently simple structure. The use of these vestiges of the posterior members is still unknown. Their feeble development debars the idea of their contributing in any way to locomotion. Certain observers maintain that they are prehensile organs, which give firmness of position on whatever bodies are embraced by the circumvolutions of the tail and trunk; or that they may even subserve the generative process. They exist in both sexes.

When in a state of entire repose, the majority of serpents love to roll themselves into a spiral mass, with the head in the centre, slightly raised above the other portions. Possessing the power of bending their bodies in all directions, except directly backwards, we at the same time frequently find them simply extended on the ground or herbage in a sinuous curve. To produce progressive motion, they merely unroll the body, and bending it into successive lateral sinuosities, bring into play the numerous points of contact presented by the anterior extremities of the ribs, and thus push along with great facility. These reptiles are frequently observed to raise the anterior portion of their body into an erect position, supporting themselves on the tail and part of the abdomen, as if with a view to survey the scene around them. The body itself is then usually quite stiff and straight, although some assume a more curved attitude, besides exhibiting a peculiar swelling or enlargement of the neck. When suspended perpendicularly from the branch of a tree, the great Boas exhibit scarcely any sign of life or motion. They descend simply by dropping themselves downwards, their peculiar form and great elasticity of structure preventing their receiving any injury from the fall; and when they reach the ground, this rapid movement, so far from proving hurtful, aids by its impulsion their terrestrial progress.

The majority of serpents (both of the innocent and the colubiform venomous kinds) defend themselves against the

Ophidian
Reptiles.

attack of their enemies by darting upon them, with the head elevated, so as to enable them to bite with greater energy. A few, such as the *Najas*, raise a considerable portion of the anterior of the body, so as to assume a very singular position. Most of them give utterance to a sharp hissing sound as a prelude to battle; and they also produce a peculiar blowing, by forcing the air rapidly through the nostrils. Several species throw themselves upon their prey with a great and sudden bound, usually seizing it by the throat; while others encircle it by a tortuous embrace, thus pressing it to death by sinewy folds. The venomous kinds make use of the same means to obtain their food as they do to defend themselves from threatened danger. Quietly stretched along the earth, they will attack indifferently whatever incommodes them; but knowing the potency of their empoisoned fangs, they are satisfied by the infliction of a murderous bite, without recourse to muscular pressure.

As snakes swallow their food entire, and without mastication, their teeth serve merely to wound and retain their prey, or to instil into it the envenomed fluid. This deadly matter is the product of certain glands of the head. These are of two kinds; the one composed, like the salivary glands of quadrupeds and birds, of numerous small granules, which secrete a fluid analogous to saliva, and destined to prepare the food for digestion; the other, of a very different nature, forming a thick sack, of which the interior is divided into numerous compartments, and distilling a liquid which, by its fatal effects on the principle of life, becomes a dreadful instrument of destruction. The salivary glands are common alike to all Serpents, but scarcely a fourth of the entire species are provided with those which secrete the poison. The teeth which conduct this fatal fluid into the wound are hollow and pierced at each extremity. They are always situate towards the anterior end of the maxillary bone, are covered by the gums, which there form a kind of sheath, and are always kept bent when in repose. The rest of the teeth, and the whole of those of the innocuous kinds, are solid, with the exception of the hollow which contains the nutritive organ of the tooth. Although these large anterior fangs are characteristic of the poisonous kinds, we yet find a considerable number of innocuous species, of various genera, which have the jaws armed with one or two teeth larger than the others, and usually furrowed by a cleft extending along the anterior face. These grooved teeth are always situate at the base or posterior extremity of the maxillaries, and it is but seldom that we perceive a second on the middle portion of the jaw. Their sole function is believed to be the pouring into their wounded prey an abundant supply of saliva secreted by the posterior part of the salivary glands, which are most voluminous in the region occupied by the teeth in question. The organization of these posterior glands entirely resembles that of the ordinary salivary ones; and recent observation has demonstrated, that the bite of species belonging to the genera *Dryophis*, *Dipsas*, and others with furrowed teeth, is followed by no fatal results, at least to the human race.¹

In studying in detail the teeth of the Ophidian reptiles, we may perceive a gradation from the solid to the hooked teeth. Each tooth in fact consists, in its earliest development, of a kind of lamella with curved margins, so as to open as it were on its anterior face. In the so-called solid teeth, this opening has become filled by the union of the margins at an early period; it continues open for a longer time in the hooks of the most venomous kinds, but in the completed state they exhibit only the two orifices destined for the entrance and emission of the poison,—the lower one

continuing to preserve the character of a longitudinal cleft. In other poisonous species we find analogous fangs, but with a continuing vestige of the groove which formerly united the two orifices. Finally, the furrow in the lengthened posterior teeth of certain innocuous species, is nothing more than the permanence of the groove now mentioned.

The solid teeth occur indifferently in all Ophidian reptiles; but their number, form, and position, vary in the different species. With the exception of the genus *Oligodon*, which is unprovided with palatine teeth, there are always four rows of teeth in the upper jaw (see Plate IV., fig. 1 c), and two in the lower. Intermaxillary teeth are not observable, except in the genus *Python*, and occasionally in *Tortrix scytale*,—the number rarely exceeding four (see figure last referred to). These solid teeth are usually all of equal length; but in the Boas they enlarge towards the extremity of the muzzle (fig. 11), while the reverse is the case in several species of *Coluber*, *Tropidonotus*, &c. The *Lycodons* exhibit some teeth more largely developed than the others at the anterior extremity of the maxillaries; those of *Dryophis* and *Psammophis* are rather unequal, several being even greatly elongated towards the centre of the jaw; those of certain species of *Dipsas*, *Homalopsis*, &c. are often furrowed; while other genera, such as *Xenodon*, *Coronella*, and several kinds of *Homalopsis*, have the base of the maxillaries armed with a strongly developed tooth of a solid structure. The number of teeth, in general, obviously varies in relation to the development of the maxillaries, and of the dental bone of the lower jaw.

The poison-gland, which forms so peculiar a character of the noxious kinds, is enclosed in a thickish tendinous envelope, hard and tenacious to the touch, and diminishing backwards into the form of a narrow ribbon, by which it is attached to the articulation of the lower jaw. Anteriorly this envelope is also restricted to a canal-shaped space, which stretches along the maxillaries, and then descends towards the orifice already mentioned, of the anterior face of the base of the hooked fang. (See Plate IV., fig. 10.) Among the poisonous serpents properly so called, this canal is folded when the fangs are in a state of repose, but easily extends in conformity with the movement of the maxillary bones. The interior of the poison-gland is subdivided into a great number of minute cells, produced by very slender partitions, which cross each other at an angle more or less acute. To this peculiar structure, so dissimilar to that of the salivary glands, is due the secretion called poison, from its fatal effect when mingled with the blood of any living creature. It is true, that the bite of even the most innocent animal may sometimes produce the most disastrous results, by a concurrence of peculiar circumstances, such as the temperature of the climate, the psychological or pathological condition of the creature bitten, or the rabid fury of that which has aggressed, and for this reason the bite of innocuous serpents may have sometimes proved deleterious even to the human race; but the poison of the injurious kinds holds its noxious qualities in its very nature, although the circumstances just alluded to may render more deadly its destroying powers.

The poison of snakes, when fresh, may be described as a transparent limpid fluid, of a greenish-yellow colour, slightly gluey, viscous, adhering to other objects when dried, and evaporating without burning when exposed to fire. It sinks in water, and when mingled with it by shaking, produces a troubled and somewhat whitish appearance. It partakes greatly of the nature of mucus; and when placed in contact with any re-active substance, we discover that it

Ophidian
Reptiles.

¹ The glands in the head of serpents have been discussed in numerous publications. See, among others, Ranby, *Phil. Trans.* No. 401, p. 377; Tiedemann, *Mém. de l'Acad. de Munich*, 1813, p. 25; Cloquet, *Mém. du Mus.*, vii. p. 62; Demoulin ap. Magendie, *Journ. de Physiol.* iv. p. 274; Meckel, *Archiv.* i. 1; and Duvernoy, *Ann. des Sciences Nat.* xxvi. and xxx. Various observations bearing on the subject will also be found in the well-known writings of Redi, Mead, Fontana, and other physiologists.

Ophidian
Reptiles.

is neither acid nor alkaline; there is nothing peculiar in its odour, and when applied upon the tongue it produces a sensation resembling that of fresh fat. Our recorded notices on the subject are, however, somewhat contradictory. Dr Mead and his associates, in certain experiments on the poison of the viper, inform us that that fluid, "when diluted with a little warm water, was very sharp and fiery when tasted with the tip of the tongue, as if the tongue had been struck through with something scalding or burning; this sensation went off in two or three hours; and one gentleman who would not be satisfied without trying a large drop undiluted, found his tongue swelled, with a little inflammation, and the soreness lasted two days." The Abbe Fontana, on the contrary, describes it as of no particular acrimony of taste, but rather resembling oil or gum; and Dr Russel makes the same statement regarding the poison even of the Cobra de Capello, a species much more venomous than any viper. The accounts of its effect upon the stomach, when taken internally, also show that doctors differ. It is long since Celsus said, "nam venenum serpentis non gustu sed in vulnere nocet." Boerhaave quotes the well-known case of Jacob Sozzi, who, at the court of the Duke of Tuscany, is alleged to have taken three drams of this poison, without experiencing any bad consequences; while Fontana affirms, that although its internal effect is not like that of a bite or puncture, it cannot be swallowed with impunity. On this point the older authors, as Dr Shaw informs us, also disagree. Matthioli asserts, that even when sucked from a wound it has proved fatal; while others confirm the prevailing opinion of ancient writers, and the experience of Cato's soldiery, that it is harmless when so received. The practice, indeed, of the Psylli and Marmarides of old,

Tame, at whose voice, spell-bound, the dread Cerastes lay,

probably proceeded upon this principle of suction. These Psylli were African tribes, and were employed, according to Lucan, by Cato, for the recovery of such of his men as had been bitten by serpents during their march among the Libyan deserts. The heroic Roman is also said to have assured his followers, who feared to drink, even in "a dry and desert land," of the translucent fountains, lest they too should be infected by serpents, that, however noxious might be the bite of these envenomed reptiles, yet the poison must lose its effects when mingled with so pure an element.

And now with fiercer heat the desert glows,
And mid-day gleamings aggravate their woes;
When, lo! a spring amid the sandy plain
Shews its clear mouth to cheer the fainting train.
But round the guarded brink in thick array
Dire Aspicks roll'd their congregated way,
And thirsting, in the midst, the dreadful Dipsas lay.
Blank horror seized their veins, and at the view
Back from the fount the troops recoiling flew.
When, wise above the crowd, by cares unquell'd,
Their awful leader thus their fears dispell'd:
Let not vain terrors now your minds enslave,
Nor dream the serpent brood can taint the wave;
Urged by the fatal fang their poison kills,
But mixes harmless with those bubbling rills.
Dauntless he spoke, and bending as he stood,
Drank with cool courage the suspected flood.

The poison of the viper, according to Boerhaave, is rendered inactive by digestion in the stomach and bowels, so that it will not afterwards exert its fatal influence on the blood; "for a whole ounce of this venom taken by the mouth will not kill an animal, while at the same time a small needle only dipped in the same fluid, and taking up perhaps not more than the hundredth part of a drop, when thrust into the blood of a living creature, almost infallibly destroys."¹ The following is Bruce the traveller's well-

known but extraordinary narrative. "I will not hesitate to aver that I have seen at Cairo (and this may be seen daily, without trouble or expense) a man who came from above the catacombs, where the pits of the mummy-birds are kept, who has taken a cerastes with his naked hand from a number of others lying at the bottom of the tub, has put it upon his bare head, covered it with the common red cap he wears, then taken it out, put it in his breast, and tied it about his neck like a necklace; after which it has been applied to a hen, and bit it, which has died in a few minutes; and, to complete the experiment, the man has taken it by the neck, and beginning at the tail, has ate it as one would do a carrot or a stock of celery, without any seeming repugnance."

This opinion, however, that the poison of snakes may be taken internally without producing any troublesome effects, has been recently contradicted by the experience of Dr Hering, at Surinam. This traveller took at different times various doses of the poison of a rattle-snake (*Crotalus mutus*) mixed with water, and suffered from its effects for upwards of eight succeeding days. These manifested themselves by pains in the larynx and other parts of the body, by an increased secretion of mucus in the membranes of the nose and œsophagus, and by frequent diarrhœa, accompanied by pain in the rectum. To these symptoms were added several others of a rather curious kind, attributable to the influence which this poison seemed to exercise even over the moral faculties.

By far the most deleterious effect, however, of this subtle fluid is produced by its mingling with the blood, through the medium of an inflicted wound. It then shows its morbid influence with a rapidity often frightful, and usually proportioned to the quantity of the poison instilled, and to the abundance with which the wounded part is furnished with those vessels which bear the stream of life. For this reason, of course, the bite of a large snake is more dangerous than that of a small one; and so also a wound in the tongue, or in any vein, is almost always mortal, while it not unfrequently happens, that when a hard or callous part is bitten, no injurious results are found to follow. Cold-blooded animals are much less affected by the bite of a snake than are quadrupeds or birds; and in the majority of invertebrated tribes it produces no effect whatever. Generally speaking, however, the smaller the victim, the more deadly are the consequences of a wound. In Europe, the human race seldom suffers fatally from the bite of a viper; and it is supposed that the poison of several would be required to kill a bullock or a horse. So at least say many modern writers; yet we cannot help remembering what Boerhaave tells us regarding a viper, which, "being enraged by the members of the Tuscan Academy," and then suffered to bite the nose of a strong bull, the ponderous creature died in a very short time. A small quadruped dies rapidly from an infliction of the slightest wound. In tropical countries, however, where the poisonous species are often of considerable size, and their venom is both more abundant and in a state of higher concentration, the effects are fatal both to man and beast. The activity of the poison, in truth, increases with the temperature of the climate.

Various experiments have been tried, with a view to ascertain the strength of this animal poison in different species of serpents, and the best means of arresting its fatal influence. The observations of Laurentius, Fontana, Russel, Davy, and Lenz, are familiar to the student of physiology, but less satisfactory in their results than might be desired, from the modifying effects of special circumstances. To obtain well rectified general inferences, it would be necessary that numerous experiments should be tried with serpents of corresponding size, existing under similar circum-

Ophidian
Reptiles.

Ophidian
Reptiles.

stances, and in relation to victims of the same constitution; and by repeating these experiments with various kinds of serpents, and taking the average effect of each kind as a result, we might in a measure ascertain the different characters of these animal poisons, of which we have as yet but a meagre knowledge.

The effect of a serpent's bite usually manifests itself without delay. A sharp pain is felt in the part pierced by the fangs, although the puncture is extremely minute, and scarcely a drop of blood may flow; swelling follows, and inflammation soon declares itself. The progressive effects upon other parts of the system are exhibited by a general feebleness; walking becomes painful, and respiration laborious and constrained; the patient suffers from ardent thirst, followed by nausea, vomiting, glimmering of the sight, and other symptoms, which, combined with acute bodily pains, often deprive the victim of his senses. Livid spots sometimes surround the wound, the dread precursors of that fatal gangrene which, spreading more extensively, ere long puts a period to existence. "His strength is poured out like water, and all his bones are out of joint; his heart is like wax, it is melted in the midst of his bowels. His strength is dried up like a potsherd, and his tongue cleaveth to his jaws, and he is brought unto the dust of death." Then, instead of the bloom of youth, the power of manhood, or the pride of beauty, we behold but a bloated corpse, the sad repulsive remnant of humanity. It may be remarked, however, that the poison of these subtle reptiles seems to deprive us of life under a considerable variety of aspects. A lethargic torpor without pain is said to follow the bite of the asp; and hence, we presume, its preference by that luxurious queen for whom Antony "lost the world." The fact, though doubted by medical observers, seems in a great measure confirmed by the examples adduced by Captain Gowdie, as recorded by Dr Russell.¹ Lucan of old has distinguished the poisonous serpents that infested the march of the Roman army over the deserts of Libya by the various symptoms which they produced; but his dreadful catalogue should perhaps be regarded rather as a piece of poetical embellishment than as a historical relation. Yet it seems now believed, that however the symptoms may vary, the nature and action of the poison is the same in all, and is in most cases to be counteracted by the same means. The virulence of the bite even of individuals of the same species probably varies according to the season of the year, just as their manners and external aspect also vary, as so beautifully described by Virgil:—

Potsquam exhausta palus, terræque ardore dehiscunt,
Exilit in siccum, et flammantia lumina torquens
Sævit agris, asperque siti, atque exterritus, æstu.
Ne mihi tum molles sub dîo carpere, somnos,
Neu dorso nemoris libeat jacuisse per herbas:
Cùm positus novus exuvius nitidusque juvenu,
Volvitur, aut catulos tectis aut ova relinquens,
Arduus ad Solem, et linguis micat ore trisulcis.²

The excessive rapidity with which death was frequently produced by the bite of venomous serpents induced Dr Mead to conclude that its fatal influence affected the nervous rather than the circulating system. But the experiments of Fontana go far to demonstrate that the venom of the viper is perfectly innocent when applied to the nerves only; but that it acts immediately upon the blood, and through the medium of that fluid destroys the irritability of the muscular fibre, and so produces death.

In further illustration of this singular subject, we may here give a brief account of the effect produced by the bite of some remarkable salt-water snakes belonging to the

Ophidian
Reptiles.

genus *Hydrus* (*Hydrophis* of our present treatise). Soon after the opening of the bar in the month of October 1815, reports prevailed at Madras that a great shoal of sea-snakes had entered the river, and that many natives while crossing had been bitten, and had died in consequence. A reward was offered for each of these creatures captured and carried to the superintendent of police. Pandauls were erected opposite to the two principal fords, and skilful natives, under the direction of Dr M'Kenzie (to whom we are indebted for the information), were provided with *eau-de-luce* and other remedies, and ordered to afford immediate aid to those who might be bitten. Many were bitten accordingly (the snakes seeming in no way loathe to expedite the result), and all exhibited the symptoms usually consequent upon the action of a powerful animal poison; but none died. We shall state a couple of cases, with the mode of treatment. A native woman, while crossing near the custom-house, was seen, on emerging from the water, to shake off something from her foot. This to several spectators appeared to be a water-snake. The woman, after advancing a few paces from the river, fell down, and was immediately carried insensible to the pandaul. On examining her feet, two small but distinct wounds were perceived on the ankle of the right leg; her skin was cold, her face livid, her breathing laborious, her pulse scarcely perceptible. A ligature was immediately placed above the wound, which had been previously enlarged with a lancet, and a piece of the carbonate of ammonia well moistened with pure nitric acid applied, while thirty drops of the *eau-de-luce* were administered nearly at the same time in a glass of water. In five minutes more a similar dose was poured down the throat, which seemed rather to increase the spasmodic affection of the chest; but the pulse at the wrist became distinct, though feeble. A third dose was repeated in three minutes more, on which she uttered a scream, and began to breathe more freely. Ten minutes had now elapsed since she had been carried to the pandaul, and in about three minutes more a tea-spoonful of the *eau-de-luce* was given, which almost immediately produced violent nausea, and a profuse perspiration. When a little salt was put into her mouth, she declared it was not salt, but sugar; and this the natives deemed an infallible sign of still-continued danger. She soon, however, entirely recovered, and merely complained for three or four days of a numbness in the limb above the wound. Another case was that of a Lascar, who was bitten by a snake while in the middle of the river. He advanced a few paces after quitting the bank, and then fell down in violent convulsions. When brought in, his breathing was laborious, his skin cold and clammy, his countenance livid, and his pulse feeble at the wrist, but distinct at the temples. A quantity of froth and foam was ejected from between his closed teeth. He too recovered, after a similar mode of treatment; but he complained for many days *that he had no left leg*. On another occasion a large healthy chicken was exposed to the bite of a *Hydrus major*, four feet long. It was bit in the foot, and in about ten minutes began to droop, and to show a slight convulsive flutter of both wings. In three minutes more it became convulsed, and at the end of seventeen minutes from the infliction of the wound it suddenly dropped down dead.³

Dr Russel has figured and described forty-three of the most common serpents of Hindustan, and of these he found only seven that were provided with poison-fangs. He informs us that a quantity of warm Madeira taken internally, with an outward application of *eau-de-luce* on the punctures, was generally successful in curing the bite of even the most venomous species. He also states that the me-

Ophidian
Reptiles.

Ophidian
Reptiles.

medicine called the Tanjore pill was equally efficacious. Each pill contains three-fourths of a grain of arsenious acid. On comparing the effects of the poison of five of the oriental species on brute animals, with those resulting from the rattle-snake and European viper, Dr Russel remarked that they all produced morbid symptoms nearly the same, although they might differ in the degree of their deleterious power, and the rapidity of its operation.

The tongue of serpents is remarkable for its great extensibility. It is protected by a rather firm skin, becomes very slender towards the anterior extremity, where it divides into two slender filaments, and is capable of being withdrawn into a kind of sheath, which opens in front of the glottis. The position of these parts varies in the different species, being placed, for example, very near the muzzle in the genus *Hydrophis*, but much further backwards among both the terrestrial and the tree serpents. The tongue of the Ophidians in general, though extremely similar to that of certain Sauians, such as *Monitor*, *Tejus*, and other genera, yet differs in the far greater simplicity of the harder parts by which it is supported; for we find, in place of a hyoid bone, composed of several pieces, merely a simple cartilaginous thread attached to the internal face of the general integument of the gular region, with its two extremities prolonged greatly backwards. This cartilage is sometimes, as in *Boa*, intimately united to the muscles of the throat, of which it intersects the fibres, its posterior extremity being then attached to the skin on the sides of the neck; but in the majority of cases, the horns of the hyoid are free, closely approached, and prolonged into the cavity of the chest, even as far as the heart. The tongue of these reptiles seems in truth, by its construction, to be a genuine organ of touch, and serving neither for taste nor deglutition, being during the latter act inclosed within its sheath. A little notch-like aperture at the end of the muzzle, which exists in most serpents except the aquatic kinds, admits the protrusion of the tongue without the necessity of opening the mouth. This movement is usually made very leisurely, although with extreme rapidity when the individual is excited either by fear or passion.¹

The use of the tongue in serpents is not exactly known. Its narrow and cylindrical form would render it unapt to aid the process of mastication, even were the teeth of a nature to perform that process. They are continually lancing it into the air, and may possibly in this way also gather moisture from grass or other herbage. It is, however, believed that they never drink. "On ignore," says M. Schlegel, "si les serpens boivent, et s'il est juste d'opiner pour la négative; toutefois on n'a jamais aperçu des fluides dans ceux dont on a examiné l'estomac."² Other authors, however, are of a somewhat different opinion. "Tout au plus," say MM. Dumeril and Bibron, "cette langue fort longue sert-elle, comme on l'a observé quelquefois, à faire pénétrer un peu de liquide dans la bouche, car nous avons vu nous-même des couleuvres laper ainsi l'eau que nous avions placée auprès d'elles dans la cage où nous les tenions renfermées pour les observer à loisir."³

The alimentary canal of the Ophidians is remarkable for its great simplicity.⁴ The œsophagus and stomach form a continuous canal, to the special parts of which it is difficult to assign precise limits. The pancreas, according to M. Schlegel, is always placed "dans la première courbure qui fait l'intestin à partir du pylore," and varies in different species both as to size and form. The spleen is of an oval or somewhat globular shape, of a rather firm consistence, and frequently concealed among the lobes of the pancreas, with which it is sometimes intimately united. The liver in

Ophidian reptiles assumes a long ribbon-shaped form, more slender at either end, sometimes imperfectly divided into a couple of lobes, and extending along the œsophagus and stomach, from the heart as far as the pylorus. The hepatic canal descends from its interior face towards the pancreas, to conduct the bile into the small intestine. The gall-bladder, which is abundantly supplied, discharges its fluid by a short conduit, which joins the hepatic canal at an angle more or less acute. The kidneys, remarkable for their lengthened form and symmetrical position, are divided into a great number of small lobes, adhering to each other by means of the cellular tissue.

Digestion, notwithstanding the activity of the gastric juice, is sufficiently slow in serpents. It would appear, in fact, that the juice in question exercises its influence chiefly in the regions near the pylorus; for it has been found that an animal withdrawn from the abdomen of a snake is always decomposed towards its lower extremity, while the portion lying nearer the œsophagus continues unconsumed. Indigestible portions, such as hair, feathers, &c., are said to be sometimes ejected by the mouth; and, according to M. Dieperink, when a serpent in a wild state is pursued soon after it has swallowed a considerable prey, it will disgorge it to facilitate the means of escape. In regard to the digestive faculty of serpents, one of the most remarkable characters consists in the strong absorbing power of the intestines. When we examine their fecal remains, we find that these exhibit as it were a dry extract of the entire prey, of which the parts incapable of liquefaction remain not only unaltered, but occupying precisely the same relative positions which they held in the living animal. If, for example, a rat has been swallowed, we find, in what at first appears a dry and unformed heap, the muzzle, the long hairs upon the cheeks, the down which covers the thin cartilage of the ears, the hair, of various length and colour, which has clothed the back, abdomen, and especially the tail, and finally the nails, in a perfectly entire state. All fleshy or softer substances have been completely absorbed; and the earthy salts, which, by their union with the gelatine, give consistence to the bones, still indicate by their colour the position formerly occupied by these osseous portions. The most complete natural analysis has been effected by means of dissolution, compression, and absorption,—and of this the desiccated mass already mentioned is the sole residuum.⁵ The infrequent meals of serpents are thus in a measure compensated by the great profit which they derive from each.

The mode in which these reptiles swallow their food is sufficiently simple. They commence by getting the head within their throat, and while the teeth of one jaw adhere to the prey, the other jaw makes a forward movement, and, fastening its teeth, draws the object inwards, till, by this alternate action of the jaws, and chiefly of the under one, deglutition is effected. The jaws, as we have already hinted, are capable of a certain separation from each other even at their basis, and an abundant supply of saliva being at the same time poured out upon the victim, a body larger in bulk than the snake itself is sometimes swallowed; and as in this case the process is slow, and but a small portion can enter the throat at a time, the reptile reposes for a considerable period, even till, with distended mouth, it seems gorged with putrefaction, presenting a hideous and disgusting picture of gluttony and sloth. When the venomous kinds swallow their prey, they do not use their poison-fangs, but lower these beautiful and highly-finished instruments of destruction into the hollow of the gums,—“sheathing them as a sword.”

Ophidian
Reptiles.

The heart of Ophidian reptiles is usually of an elongated form, and is remarkable for its distant position from the head. It is composed of two spacious auricles, separated from each other by a membranous division; the ventricle, on the contrary, is imperfectly divided into two rather narrow cavities by a partition which takes its origin from the base of the heart, and loses itself amid the fleshy fibres of that region. The walls of the auricle, although fleshy, are slender,—those of the ventricle are of considerable thickness, especially on the left side of that portion which extends in the form of a conical appendage beneath the left auricle. Each auricle communicates with the ventricle by means of a broadish opening, susceptible of being closed by a valve. The right auricle receives all the veins, which form, with the exception of the left jugular, prior to passing through the wall of the auricle, a kind of sac of greater or less extent, which, in addition to the ordinary tunics, exhibits a distinct muscular coat. Two large valves serve to close the common entrance of the veins into this auricle. When the blood has attained the right chamber of the ventricle, it is driven into the pulmonary artery, of which the embouchure offers two valves; comprised at its base in the common trunk of the aortas, this artery curves itself beneath the left aorta, and approaches the lung, of which it margins the posterior face before entering the interior of that organ. A single pulmonary vein, piercing the lung behind the artery of the same denomination, carries the oxidized blood into the left auricle, which is of a conoid form, and less spacious than the right one. This oxidized blood, after having passed into the left cavity, is pushed towards the right side, where we find the embouchures of the two aortas, of which each exhibits a pair of semicircular valves, even when these openings are united into one.

We shall now devote a few lines to the respiratory organs. When we observe a serpent in a state of repose,—

“as on the grassy herb
Fearless, unfear’d, he sleeps,”—

we may see that its body alternately dilates and contracts by the play of the ribs, and that this movement is repeated slowly, yet at regular intervals. But we may also perceive that the nostrils are closed for a longer, and consequently an unconforming period, during one of which the body is contracted and dilated perhaps thirty times. It results from this observation that the lungs of Ophidians, besides their ordinary function, fulfil that of serving as reservoirs of atmospheric air, which, though replenished only by a single inspiration, contain a quantity sufficient to admit a continuous oxidation of the blood by the contraction of the lungs. When the oxygen is totally absorbed, expiration takes place, and a supply of fresh air is drawn in. The configuration of the lungs undergoes many modifications in the different races of Ophidian reptiles. The form is usually that of a simple conical sac, extending from the heart toward the lower regions of the stomach, where it ends in a membranous pouch. The trachea, composed of numerous demi-rings united anteriorly by a membrane, terminates in the origin of the lungs by an oblique opening. The latter organ is divided more or less completely into two *bronchi* in *Boa*, the majority of *Tortrix*, the genus *Dipsas*, and others; and in these we may perceive the vestige of a second lobule of the lung, sometimes half as large as that on the other side. A singular peculiarity is observable among the sea-serpents. In *Hydrophis colubrinus*, for instance, the tracheal pipe is prolonged into the hypochondriac region, where it terminates in a membranous sac, extending to within a couple of inches of the anus; but in place of a membrane uniting the rings of the trachea, it is the lung itself that envelopes that tube throughout its whole length.

Ophidian
Reptiles.

The small size of the brain in serpents is obvious in all, and becomes very conspicuous in relation to the size of the head, when we select for observation any of those species in which the organs of manducation are strongly developed. The two hemispheres are prolonged by restriction into the olfactive lobule, so that the latter part is borne as it were upon a pedicle. We observe the optic lobules on their posterior face, and passing beneath the hemispheres towards the eye, to form the optic nerve. The cerebellum is a very small organ, situated behind the optic lobules almost uniform with the spinal cord, or offering but an inconsiderable enlargement. The grand sympathetic nerve is interlaced at so many points with the *par vagum*, that it is next to impossible to trace its origin with any certainty.

As to the intellectual faculties of these reptiles, we know that Satan found

“The serpent, subtlest beast of all the field;”

and we doubt not that, even in our own days, they may be placed at least upon an equality with the Saurian and Chelonian orders. The reproductive power with which their separate parts are said to be endowed has probably been the subject of some exaggeration; and it seems certain that when the tail or other important portion has been destroyed by mutilation it is altogether incapable of being reproduced. The sense of smell is believed to be by no means acute in these reptiles. The nostrils vary in the difference genera in respect to form, size, and position. It may, however, be stated as a constant rule, that the purely aquatic species have the nostrils small, directed upwards, and for the most part susceptible of being closed by means of a valve, while those of the terrestrial and arboreal kinds are usually lateral and open. Among the burrowing serpents these openings are almost always of an orbicular form, and of very small dimensions. In the genera *Trigonocephalus* and *Crotalus* there is a cavity on each side of the muzzle, behind the nostrils, of which the use is still unknown. The eye is probably defective in the power of distant vision, though sufficiently acute for all the ordinary purposes of a serpent's life. It is covered over by the external skin, of which, however, the tunics in that quarter are extremely thin and diaphanous, and present themselves under the form of a hemispherical lamella adhering to the scaly plates which surround the orbit. There is thus no apparent eyelid to the visual organs of serpents, a slight edging of the skin forming their only protection.¹ The supposed absence of this part was presumed by the ancients, and has been recorded in the writings even of modern anatomists of the greatest skill. But more recent researches, undertaken by M. Cloquet, and verified by Baron Cuvier and M. Dumeril, have demonstrated that the eye of Ophidians is provided with a single lid, large though immovable, and incased in a projecting frame, which forms around the orbit a series of scales, variable in number, though usually amounting to seven or eight. When the general covering is renewed, we find that a delicate coating of the eye is likewise thrown off as a portion of the exuvæ. The structure of the ear in serpents seems to demonstrate that these creatures are dull in their sense of hearing.

The general envelope of Ophidian reptiles forms a kind of cuirass, which enables them to withstand the influence of the elements and the effects of external accidents. To conform to the movements of the body, and the occasional enlargement of its parts, this covering, we need scarcely say, is composed of a multiplicity of separate compartments, of which the smaller are called scales, the larger plates. These parts are composed of much thicker layers of the integument than the intervening portion, which consists of a delicate skin, seldom visible except when the body is more

¹ “Nous avons déjà dit qu'il n'y avait pas de paupières apparentes dans les serpents, et que ces animaux semblent, par cela même avoir l'œil fixe, et être toujours éveillés.” (*Erp. Gén.* i. 102.)

Ophidian
Reptiles.

than usually distended, and for this reason almost always colourless, being unsubjected to the influence of light. In certain species of the genus *Tropidonotus*, however, the mucous membrane of the neck is so tinted as to exhibit a beautiful vermilion red between the scales; and the scales themselves in many species exhibit colours, both fixed and iridescent, of great brilliancy:—

“With burnished neck of verdant gold, erect
Amidst their circling spires.”

The general tinting depends in a great measure upon the condition of the epidermis, and is always freshest and purest immediately after the casting of the slough or superficial skin. The total amount of longitudinal rows of scales is almost always an unequal number, there being a single range rather larger than the rest along the centre of the dorsal region, with an equal number on either side; but to this rule *Herpetodryas carinatus* forms an exception (the only one perhaps throughout the order), there being a double central row of scales along the back. The form of the scales is greatly varied, some being rounded on the margins, others truncated at the extremity, or prolonged into a sharpish point. The greater number are what naturalists call *imbricated*, that is, lying slightly over each other like the tiles of a house; but almost all sea-serpents have the scales of a hexagonal form, with the epidermis very thin.

The median line of the lower parts is usually covered by a range of broad scaly plates, of much larger dimensions than the ordinary lateral and dorsal scales; and the caudal plates are generally different from those of the abdomen. The latter form a single uniform range from the anus to the throat, where they disappear. They are sometimes narrow, as in the genera *Boa*, *Tortrix*, &c., and in such cases resemble the scales of the back; but in the far greater number they are so broad as to encroach even on the flanks, and thus occupy a large proportion of the circumference of the body. The plates beneath the tail do not form a single central range, except in *Boa*, *Eryx*, and a few other Ophidians, the majority of the order having the part in question provided with a double row of plates. We may add that the terminal plates of the abdomen also not unfrequently partake of this divided character.

The head of Ophidian reptiles is rarely clothed with scales of a character similar to those of the body. They are larger, and of a more determinate and symmetrical form; and as they offer distinctive characters of easy application, they have received from M. Schlegel various names, in accordance with the position they occupy, such as vertical, occipital, superciliary, frontal, rostral, labial, ocular, frenal, temporal, mental, and gular.¹

The system of coloration which prevails among these insidious creatures is very varied, and admits of numerous exceptions to any general laws which we might attempt to establish in its illustration. In numerous species there is a beautiful accordance between the tinting of the body and the colour of the places they inhabit; thus many tree-serpents are of a uniform greenish hue, exactly similar to that of the foliage by which they are overshadowed, while several kinds of *Dendrophis* and *Dryiophis* seem rather to imitate the small and leafless branches. In the genus *Dipsas* the colours recall to mind those of the mossy trunks of ancient trees; fresh-water snakes are usually of a sombre uniform hue; while the marine species partake of those clearer tints of green and blue which beautify the pellucid billows of the up-heaving sea. Such as dwell in dry and desert lands are often to be scarcely distinguished from the parched sand by which they are surrounded; while others, which affect a more varied soil and richer vegetation, are adorned with the gay and gorgeous colour-

ing of flowers, or the metallic splendour of the mineral kingdom. Several have their bodies encircled by alternate bands of crimson and black upon a pearly-white or delicate yellow ground, and present an aspect as richly adorned as any we can discover throughout the entire range of the animal world. Among the more beautiful may be mentioned *Coronella venustissima* and *coccinea*, *Lycodon formosus*, several species of *Tortrix* and *Heterodon*, the majority of the genus *Elaps*, *Naja lubrica*, *Dendrophis ornata*, and *Dipsas macrorhina*. Numerous other species are equally remarkable, both for the splendour and diversity of colour by which they are adorned; but as these bright hues are subject to numerous causes of variation, from age, sex, and season, it results that among no order of created beings is the always uncertain character of colour to be less depended on than among the subjects of our present dissertation. It seems, however, established as a general law, that the younger individuals have the liveliest and most distinct tints, and that these in more aged examples are not unfrequently effaced, or fade away, as we find in *Coluber canus* and *melanurus*, *Homalopsis buccata*, *Xenodon severus*, and others. The power of speedy and spontaneous change of colour does not, however, seem to be a possession of the Ophidian order, as it is of so many of the Saurian tribes. Yet a few of the arboreal serpents have been occasionally observed to modify their living tints from time to time.

The natural colours of these creatures can scarcely be judged of from specimens imported to our cabinets from foreign climes. The spirit in which they are preserved is not the spirit of beauty. Black, brown, ochry-yellow, and several other tints, do not altogether lose their lustre; and *Calamaria arctiventris* and *brachyorrhos*, *Tortrix maculata* and *xenopeltis*, *Coronella rufula*, *Lycodon Hebe* and *subcinctus*, *Coluber constrictor*, *Æsculapius*, and *melanurus*, and several kinds of *Naja*, *Homalopsis*, and *Vipera*, may be named among those which are most easily preserved.

In discussing the various branches of natural history, it is the practice of authors to state the *uses* of each particular tribe of animals to the human race. We fear that in relation to our present subjects a single paragraph may suffice. Serpents certainly confer benefit by destroying other injurious creatures, such as small mammiferous vermin, worms, insects, and mollusca of various kinds. They were formerly used in medicine, though that practice, we believe, is now confined to the ignorant and superstitious; yet it has been recently stated that Dr Marikrosky, of Rosenau in Hungary, has employed the gall of serpents with success in epileptic cases.² It is well known that the flesh of the viper has been highly esteemed, both by ancient and modern physicians, as a restorative and strengthening diet. This idea, as Dr Shaw has well observed, seems to have originated from the reptile casting its skin, a natural process, viewed by the vulgar as a renovation of youth; and a snake being made the emblem of health, and consecrated to *Æsculapius*, may have depended on the same idea. The flesh of the viper was used by the ancients in leprosy and other cases. “The Greek physician Craterus, mentioned so often by Cicero in his Epistles to Atticus, cured, as Porphyrius relates, a miserable slave, whose skin in a strange manner fell off from his bones, by advising him to feed on vipers’ flesh in the manner of fish. Antonius Musa, physician to Octavius Cæsar (Augustus), is said by Pliny to have ordered the eating of vipers in the case of otherwise incurable ulcers, which by this method were quickly healed; and Galen says that those who are afflicted with elephantiasis are wonderfully relieved by eating vipers’ flesh dressed like eels.”³ According to Lopez, the Negroes of the coast of Congo eat roasted adders, and regard them as delicious

food. It is well known that the credulous Sir Kenelm Digby, with a view to recover his wife, the Lady Venetia, from consumption, caused her to feed on capons fattened with vipers. The flesh of the viper is still used in Italy and Spain as a remedy in consumption. But we need not detain our readers with more of these, at best, ambiguous views. To proceed with our natural history.

In European countries the copulation of serpents usually takes place, in fine weather, during the months of April and May, and three or four months elapse before the eggs are laid. Incubation is effected within the body of the female; for, on opening an egg immediately after exclusion, we almost always find a foetus more or less developed, sometimes entirely formed. In the latter case, the so-called shell is merely a delicate membrane, through which the young can force their way, even at the moment of parturition. In the greater number of species, however, the eggs are composed externally of a resistant covering resembling parchment, the young being very imperfectly formed at the period of deposition, and requiring sometimes a month or more before they are hatched. It is merely this difference in the times of final exclusion that constitutes the distinction between the viviparous and oviparous kinds, these being otherwise essentially the same. All Ophidians are in truth oviparous; and those naturalists are in error who compare this seemingly viviparous generation to that of mammiferous animals, in which the young are nourished by the placenta of the mother. According to M. Herholdt,¹ the conditions most favourable to the development of these embryos are humidity, produced by a feeble vegetable fermentation, with a proportional temperature (between $+20^{\circ}$ and $+6^{\circ}$ R.), and under circumstances likely to favour absorption and evaporation through the external tunic of the egg. Hence their love of dunghills, or heaps of leaves piled up in places open to the sun.

The supposition entertained by many is incorrect, that poisonous serpents always produce living young, and that the innocuous kinds as constantly deposit eggs. This diversity in the generative process does not seem to bear any relation to the organization of the species; at least we find the two modes exemplified in nearly-related species of the same genus. Thus the harmless *Coronella laevis* produces young as lively as those of the common viper; *Boa murina* is also viviparous; while the deadly *Najas* and several others lay eggs. The number of young ones varies in different species. M. Schlegel did not find above ten in several kinds of *Calamaria*, from twenty to twenty-five in the genus *Coluber*, and above thirty in *Trigonocephalus atrox*. The offspring usually differ from their parents in being of more lively colours, with the head blunter and rounder, the eyes larger, and the scales and other appendages of the epidermis less raised. They are, however, furnished with teeth exactly like those of their respective parents, and of which they do not fail, when occasion offers, to make speedy use. The venomous kinds instinctively elevate and depress their poison-fangs, as if ready from the first to defend themselves against that persecution to which their race is subjected. The European kinds are known to change their skins about five times every summer; that is, once a month from the end of April to the beginning of September. They are capable of long-continued abstinence, independent of the lethargic state into which the northern species fall in winter. A *Boa constrictor* sent from Surinam to Holland fasted continuously for six months. The age to which serpents attain is to us unknown.

Destitute of the power of long-continued locomotion, serpents never attempt to travel far from the places of their birth; and thus, even in our own days, they still represent more accurately than do the other classes of the animal kingdom the positions in which they may be supposed to have been originally placed.

One of the most curious general facts in the distribution of serpents is their apparent absence (at least so far as the land species are concerned) from the numerous islands of the vast Pacific Ocean,—a circumstance not altogether to be accounted for by the isolation of these various groups, seeing that those of the Indian Archipelago particularly abound with serpents. Another fact seems still more firmly established, that the reptiles of the New World are all specifically different from those of the Old,—a peculiar feature in the history of their class, in so far as some quadrupeds and birds are common to both countries. At the same time it may be borne in mind, that it is only the species of very northern portions of the two continents which are in any case identical, and that as these northern portions are almost, if not entirely, destitute of reptile life, the field is greatly narrowed, so far as that form of existence is concerned. The snakes of South America are in general very distinct from those of the northern portions of the New World, although a few are identical. Several of the southern species inhabit the West Indies and the warmer parts of the United States, where they form what may be termed *climatic varieties*. Other species more characteristic of a large extent of North America, reach as far south as Mexico and the Antilles. America in general, especially its equatorial districts, is almost as rich in snakes as the Indian islands. It is otherwise with New Holland, where these reptiles are by no means numerous, but where the species are peculiar to the country. The serpents of Japan seem, without exception, to belong to a particular species not hitherto observed in other quarters of the world. The numerous islands of the great archipelago of the Indian Ocean produce in several instances identical species, and these, moreover, are not unfrequently the same as those of Malacca, Bengal, Hindustan, and Ceylon. If we may judge from the few known species, the serpents of Madagascar may be regarded as peculiar to that vast island. Africa, compared with other great equatorial continents, cannot be said to be very rich in these reptiles. Its southern portions produce species entirely different from those of Europe and of other countries; but these species have a wide range in Africa itself, being in many cases spread over all its intertropical regions, and even its northern parts. These comparatively northern countries, in addition to some peculiar species, produce several others which likewise inhabit the shores of both sides of the Mediterranean. Many of our European serpents are found over a large portion of temperate Asia,—a region which appears to produce but a small proportion of peculiar species.

The geographical distribution of families and genera,—these being viewed as representing various leading forms,—affords an equally curious subject of observation. We may notice, in the first place, that the venomous sorts are distributed, with the exception of a few islands, over whatever countries produce serpents of any kind. These venomous species bear no determinate co-relation, as is often supposed, to intense heat; for they occur in cold and temperate countries equally with innocuous kinds. But their aggregate number is much more limited than that of the latter; for while we reckon the total number of known Ophidians at 263,² we do not find above fifty-seven

Ophidian
Reptiles.

¹ *Oversigt*. 1830, p. 4.

² We here follow the computation of M. Schlegel, who probably proceeds upon the idea, that the actual species have been nominally multiplied by the misapplication (and duplication) of various names. The amount must have been considerably greater in Humboldt's opinion, as that illustrious writer incidentally states that equatorial America produces 115 serpents out of the 320 which form the Ophidian order. Daudin, even in his time, described about 313 supposed species, of which 80 are regarded as venomous and 233 as in-

Ophidian
Reptiles.

of these endowed with injurious attributes,—that is, the proportion is not much more than one to five. This proportion, however, is not maintained throughout the various countries of the globe,—the venomous kinds seeming to be comparatively more numerous in open sterile countries. Of this, Africa and New Holland furnish examples,—the venomous species of the former continent being to the innocuous kinds as one to two or three, while of the ten species (or thereabouts) of ascertained New Holland species, not fewer than seven are venomous. In general, the number of individuals of each species is much more limited among the venomous kinds, as these live in an isolated manner, and rarely multiply so as to become abundant. Local circumstances sometimes favour an exception to this rule, as in the case of the *Trigonocephalus lanceolatus* of Martinique and St Lucia, and that of the Dalmatian *Viperus ammodytes*. The sea-snakes, all of which are poisonous, are likewise of a gregarious nature.

Excepting the anomalous group called *Tortrix*, there does not seem to exist any genus of serpents which is spread over all countries capable of maintaining reptile life; and this restriction seems to illustrate the intimate relation which subsists between the organization of these beings, and the countries they inhabit. For example, the Colubers properly so called, which are destined to dwell in countries which are either well wooded, or marshy with abundant vegetation, have not yet been observed in New Holland, and are so rare in South Africa that only a single species has been found there, and that of a somewhat anomalous nature, in so far as its characters exhibit an approach to those of species which dwell by preference in sandy deserts. A similar observation applies nearly to the genus *Coronella*, composed of species which inhabit marshy plains, or such as are covered by brushwood. None of these occur in New Holland (which is noted for its frequent want of water), while the South African kinds differ from the typical species of the genus. The *tree-serpents* are characteristic of equatorial countries, inhabiting of course only those portions which fulfil the conditions of their existence,—that is, are well wooded. The three genera which compose the family are found both in the Old and New World; but it is noticeable that the species of the genus *Dipsas* of America do not attain to so great a size as the majority of those of India; while the genus *Dryophis* in America forms a true geographical division of the group, in so far as the dental system and muzzle are less developed, and the pupil of the eye is orbicular. The fresh-water snakes, comprised in the genera *Tropidonotus* and *Homalopsis*, occur abundantly in countries rich in permanent lakes, and watered by continuous rivers. They are thus well known in Asia, America, and even Europe, but are extremely rare in Africa, and unknown in New Holland. The genus *Homalopsis*, indeed, which contains the essentially aquatic species, does not occur in Africa, but predominates in the New World, so rich and unrivalled in its mighty reservoirs of water.

Ophidian
Reptiles.

The geographical distribution of the *Boas* exhibits some facts worthy of record. The whole are peculiar to warm countries. The genuine species are confined to South America; their analogues in the ancient world being the *Pythons* of India, although in the latter country we also find several serpents very similar to Boas, but of very small size, and of which none exists in the Western World, except a single representative in the island of Cuba. The genus *Acrochordus* forms a limited group, entirely confined to the East Indies. Of the venomous serpents, it is chiefly the vipers, and perhaps a few rattle-snakes, which make their way into temperate or colder countries, the majority of the genera occurring in intertropical regions. Of the colubri-form venomous serpents, the genus *Elaps* is the only one which occurs in both worlds; and it is not improbable that the American species will be found to constitute a geographical group, distinguished by their peculiar coloration, and certain small distinctions even in form. The Indian species of the genus last named are longitudinally striped, instead of being ringed with red and black, while those of New Holland present some anomalous features. The genus *Bungarus* is proper to the East Indies, where also are found certain *Najas*, although the majority of these prefer a drier and more sandy soil,—a circumstance which explains their greater predominance in Africa and New Holland. The fact does not seem to admit of easy explanation, that *salt-water serpents* should be found almost exclusively in the Indian seas, from Malabar to the great Pacific Ocean. In regard to the venomous kinds properly so called, of the three genera of which that division is composed it may be observed, that one, *Viperus*, is proper to the ancient world; that another, *Crotalus*, is confined to the new; while a third, *Trigonocephalus*, occurs in both. These last-named reptiles dwell in great forests or in well-wooded countries, and for that reason are not observed either in Africa or New Holland, where they are replaced by vipers; but it may be mentioned that the viper of New Holland is an anomalous species, while such as inhabit Europe equally depart from the typical form, and tend towards that of *Trigonocephalus*. In the genus just named two divisions may be established,—one composed of species with the head clothed with scales, and which inhabit more particularly tropical countries; another formed of species with the head covered by scaly plates, and which extend into temperate regions.

The preceding are a few of the most general facts in the distribution of Ophidian reptiles. We shall now notice some of those peculiarities which distinguish particular continents,—and, first, of Europe. We here find no species of the genera *Calamaria*, *Heterodon*, or *Lycodon*, no genuine tree-serpents, no species of *Homalopsis* or *Boa*. We never meet in Europe with any salt-water serpents, nor with any of the colubri-form venomous kinds; and the poisonous tribes in general are represented merely by a few vipers. That the entire order of Ophidian reptiles has its great centre of dominion in sultry regions, is made manifest by the fact,

nocuous, which gives a greater proportion to the former than they are at present entitled to. Nearly 400 different kinds of serpents are believed to exist in the Paris Museum, although we know not with what degree of critical accuracy that enumeration has been made; but several Ophidians, not true serpents, are included in the lists of others, which are excluded in the enumeration of Schlegel.

We do not ourselves possess the means of ascertaining the total number of reptiles now known to naturalists; but the following table exhibits the amount (as in 1834) in the National Museum of Paris, compared with the number described in the works of three principal writers on the class in question:—

	Lacépède, 1790.	Daudin, 1805.	Merrem, 1820.	French Museum, 1834.
Chelonians...	24	62	62	97
Saurians.....	56	88	83	168
Ophidians.....	172	315	348	391
Batrachians.....	40	91	87	190
	292	556	580	846

We may conclude this note by observing, that the unfortunate Wagler, in his *Natürliches System der Amphibien*, 4 vols., Munich, 1830, with folio atlas of plates, has described no fewer than 248 genera of the reptile race.

Ophidian
Reptiles.

that the temperate and northern parts of Europe produce no peculiar species, that is, no species which do not occur equally, if not more abundantly, in the southern districts of the continent, where we likewise find several kinds native to the neighbouring countries of Asia and Africa. Limits, however, may be assigned to several species, and this circumstance naturally gives rise to some curious observations. The common viper, for example, inhabits all the central parts of Europe, and is even spread over temperate Asia as far as Lake Baikal. It is well known in Sweden, spreads westwards into Britain, is frequent in Jura, Islay, and some others of our western islands, but is unknown in Ireland. The western boundary, however, of the great mass of individuals of this species may be stated to be the river Seine, while the Alps appear to form its southern limit.¹ In the southern portion of western Europe our viper is replaced by another species called the aspic (*Vipera aspis*), which spreads from Trieste over Italy into Sicily, through Switzerland and over France, passing beyond the Seine towards the Pyrenees, and into Spain. The southern parts of the east of Europe produce a third species of this genus, *Vipera ammodytes*, which we find to spread from Styria as far as the south of Hungary, and into Greece, Dalmatia, Sicily, and probably likewise Calabria. This distribution of so nearly-allied species seems modified by, if not dependent on, the nature of the territories which each inhabits. The first prefers, in general, heathy lands and places of a rather moist and wooded character, the second affects a dry and arid country, while the third rejoices in a rocky region. No local or climatic varieties of these vipers have been yet observed; but it is otherwise with several other snakes, which have a widely extended distribution over Europe; for example, *Coronella lævis*, and *Tropidonotus natrix* and *viperinus*. These species, of which the former two inhabit almost the whole of northern and central Europe, the last not extending further than the fiftieth degree of north latitude, occur equally in the south of Europe, where they form well-marked local varieties. Thus, in Spain, *Trop. viperinus* has the back longitudinally rayed; and a corresponding character occurs in Sardinia in relation to a species common in that island, while the Sicilian individuals present some slight additional disparities. *Coronella lævis* forms in Italy a peculiar climatic variety, of a paler hue than usual, which extends as far north as Marseilles. *Coluber Æsculapii*, which inhabits the south of Germany, is also found in Dalmatia, Italy, and Provence. *Col. viridiflavus* has been observed over all the south of Europe, Greece, Hungary, Dalmatia, Italy, Sicily, Sardinia, and as far north as France and Switzerland. *Col. hippocrepis* occurs in Spain and Sardinia, while *Col. leopardinus* is a native of Sicily, Dalmatia, and Greece; but, so far as known, neither of these kinds is met with in Italy. Neither has *Psammophis lacertina*, so common in Dalmatia, in Spain, and a large portion of France, been ever found either in Italy or the adjacent islands. The southern countries of Europe produce several serpents which are not characterized by a great extent of distribution. Such are *Xenodon Muchahellus* of Spain, and *Psammophis Dahli* of Dalmatia (the latter, however, which approaches the tree-serpents in its slenderly elongated form, being found also in Greece), and *Tortrix eryx*, confined to Greece as a European species, but elsewhere well known amid African and Asiatic deserts.

A careful and more extended study of the distribution of animal life in Africa would be found to illustrate many curious relations both in descriptive zoology and physical geography. No other continent furnishes more striking proofs of the connection between the natural characters of

a country and its animal inhabitants. Thus, after acquiring some knowledge of the physical constitution of Africa, we might almost predicate the prevailing features of its natural history. The leading character of this continent is the presence of vast sandy plains or deserts, and elevated plateaus, of which the vegetation is either entirely extinguished, or held by a precarious tenure. Acted upon continually by a burning sun, the flat unvaried surface is altogether unfit for the production of those vapours which, in a state of atmospheric condensation, produce our refreshing showers of frequent moisture, and the more stormy accessories of hail and snow. The great mountain ranges being few and far between, the intermediate regions possess no perennial fountains of refreshing water, no "clouds of morning dew," to clothe their arid wastes with verdure. Hence the absence of that mighty power which in America slumbers amid the most unpeopled wilderness, and makes, when aided by the hand of man, the "desert blossom as the rose." It results from the fact of so large a portion of Africa being destitute of rivers, and consequently of forests and other lowlier vegetation, that we there find but a small number of those animals which inhabit woods and fresh waters, while such as are fitted to scour over vast plains occur in great abundance. Hence the absence of stags and the existence of vast troops of antelopes; hence also the scarcity of squirrels and other wood-haunting Rodentia, and the increase of certain swift-footed terrestrial kinds. The characters of reptile life exhibit an equal conformity with the spirit of these observations. Africa produces perhaps a greater number of land-tortoises than all other portions of the world combined; but the flesh-water kinds, with the exception of a single *Emys*, and one or two species of the genus *Trionyx*, are nearly unknown, while frogs and toads are also few in number. The same observation applies in reference both to the aquatic serpents and the wood-loving kinds. The genera *Dryiophis* and *Homalopsis* are entirely wanting, and not more than one or two species are known of each of the genera *Dipsas*, *Dendrophis*, and *Tropidonotus*. In so vast a continent, however, in spite of its prevailing character of aridity, there must be numerous exceptions; and we know how far-flowing are the waters of the Nile and the Niger, how lofty and continuous the mighty mountains of Abyssinia. Many an umbrageous river, we doubt not, still rolls its crystal waters directly towards the all-absorbing sea, or fills up the glassy depth of unimagined lakes, whose beautiful shores are haunted by many unknown forms of existence,—

Fair creatures, to whom Heaven
A calm and sinless life, with love, hath given.

Our knowledge of African snakes, however, is still insufficient to admit of any accurate geographical sketch of their distribution being laid before our readers, for we have no data on which to assign limits to the majority even of the best-known species. Egypt and Abyssinia, Algiers, a part of Senegambia, the coast of Guinea, and the Cape,—these are the chief points from which any precise knowledge has been derived. Yet we may hazard the assertion, that Africa in general is much poorer in reptiles, particularly serpents, than either Asia or America. The number of genera is equally circumscribed; and the same observation applies to our present class as has been made in relation both to the higher animals and plants of Africa, to wit, that the species of certain genera are very numerous, and that several different kinds often inhabit the same places. Towards the southern extremity of the continent we meet with four species of the genus *Coronella*, as many of the genus *Naja*, and three *Vipers*. The other genera which

Ophidian.
Reptiles.

¹ It is indeed alleged to have been met with, though sparingly, in the valley of the Po, and as far as the Florentine territory.

Ophidian
Reptiles.

occur there have each only a single representative. These reptiles belong almost without exception to species peculiar to the African continent. *Lycodon Horstokii* and *Naja rhombota* occur on the coast of Guinea, which produces likewise *Psammophis moniliger*,—but a local variety, resembling that which is found in Egypt. In Senegambia we find three species of tree-serpents, of the genus *Dendrophis*, which differ from those of the Cape, but of which one (*Den. picta*) is spread over a vast extent of the Asiatic world, as far south-eastwards as New Guinea. The inter-tropical countries of Africa produce *Python bivittatus*, characterized by an equally great extension, as it is found both in Java and the Chinese empire. *Viperus arietans* of the Cape is found as far north as Abyssinia, where it forms a variety of a paler hue. Northern Africa produces several serpents of species different from those of other parts of that continent. Such are *Tortrix eryx* and *Vipera echus*, which elsewhere inhabit as far south as Hindustan,—the *Cerastes*, a species of *Dipsas*, and several kinds of *Coluber*. Other species, such as *Naja haje* and *Psammophis moniliger*, differ more or less from their southern representatives. The Mediterranean countries of Africa nourish several kinds which occur in the south of Europe; and this analogy between the two continents is very striking when we compare, not the serpents alone, but the zoological productions in general, of Barbary, with those of Portugal and Spain. No serpents have been yet observed in the islands situate within the radius of Africa, and it appears certain that they do not exist in the Canary Islands.

The great island of Madagascar, of which the natural productions are as yet but slightly known, appears to be zoologically allied to Africa chiefly by the species of its western side; and although the eastern slopes of its great mountain chain exhibit features of an Asiatic character, its totality presents a very distinct and peculiar complexion. With the exception of *Tropidonotus schistosus*, all the known serpents belong to particular and elsewhere undiscovered species. For example, the *Langaya*, an anomalous and very remarkable species of *Dryophis Herpetodryas Goudoti* and *Rhodogaster*, and *Dipsas Gaumardii*, are all peculiar to Madagascar. The Mauritius produces a very beautiful species, *Coluber miniatus*, and a small Boa (*B. Dussumieri*) of an extremely attenuated form. From the Seychelles Islands we know of no serpent but a species of the genus *Psammophis*.

With the exception of its two magnificent Indian peninsulas, Asia is not so productive as might be expected of the reptile race. The temperature of a vast portion of the loftier and central, and *a fortiori* of the northern districts, is subjected to a low temperature during many months of the year. We know that Northern Asia, Siberia more especially, produces several animals of the higher orders, identical with some which inhabit the more rigorous parts of Europe; but the alleged identity of the Siberian species of *Tropidonotus* and *Viperus* may possibly require confirmation. A curious Ophidian, peculiar to the southern countries of Siberia, is *Trigonocephalus halys*, intermediate organically between the vipers of Europe and those species of its own genus which have the head furnished with scaly plates. The deserts to the south of the Caspian Sea, which are prolonged on the one side into Hindustan, on the other by means of the Iran, into Arabia and Syria, thus connecting with the desert tracts of Africa, produce a few species common alike to corresponding portions of both continents. We are still in almost total ignorance of the snakes of the great plateaus and other portions of Central India.

The reptiles of Japan present this peculiarity, that while the Batrachian and Chelonian orders exhibit several species identical with those of Europe (*Rana esculenta* and *temporaria*, *Hyla arborea*, *Emys vulgaris*, &c.), the Saurian and Ophidian groups seem to consist of species alto-

gether unknown in Europe. However, we know as yet but in part, for the Japanese species hitherto collected comprise, in addition to the genus *Hydrophis*, merely three species of *Coluber*, two of *Tropidonotus*, and a single *Trigonocephalus*.

The island of Ceylon, though not extremely remote from the coast of Coromandel, produces several serpents not known in continental India, such as *Tortrix maculata*, *Calamaria scytale*, *Lycodon carinatus*, and two species of *Trigonocephalus*.—*Trig. hypnale* and *nigromarginatus*. It is along the Ceylonese shores that we first perceive certain species of the genus *Hydrophis*, those singular snakes which dwell exclusively in the sea, and occur from the island in question over all the intertropical marine waters east of Malabar, and as far as Polynesia. The number of Ophidian species which inhabit the Gangetic Peninsula, without spreading into the great islands of the Indian Archipelago, is limited. Such, however, are *Tortrix eryx*, *Coronella Russeli* and *octolineata*, several species of *Coluber* and *Lycodon*, *Dipsas trigonata*, several kinds of *Tropidonotus*, *Elaps trumaculatus*, and some vipers. The great islands themselves, with their smaller dependencies, are regarded by M. Schlegel as presenting a most interesting field for the study of zoological geography, and the observation of those local races, constituted by the diversities observable in apparently identical species placed in different localities. These islands are of the first rank as to size, situate within the tropics, covered by an abundant vegetation, and inhabited by innumerable tribes of living creatures of every class and kind. They are separated from each other by seas of no great breadth, yet sufficient to present, as matters are now constituted, an insurmountable barrier to the migration of the majority of species. Now when we find the same creatures inhabiting many different and distant islands having no communication with each other, we may reasonably infer that each insulated tract of land has borne its own inhabitants since the relations of our earth's surface became as they now exist, and that the individuals of each species form in every island a family group, which will exhibit, when compared with the corresponding species in other islands, certain modifications produced by the disparities of their position. Experience has proved the accuracy of this assumption. It has not unfrequently happened, that the same species has been discovered to inhabit Sumatra, Java, Borneo, Timor the Celebes, the Philippine Islands, and continental Asia, and in each locality has been observed to present some constant though extremely slight distinction. Now it would never do to regard these as so many distinct species. They are only local or climatic varieties, the origin of which may be obscure or incomprehensible (as are many things besides), but which we doubt not would show their identity, by each recognising the individuals of their kind, and by breeding together, could they be transported from one to another of their sea-girt isles. Innumerable examples of these climatic differences might be adduced, were we to extend our observations throughout the vast range of the animal kingdom; but here a few examples from the reptile races must suffice. The *Najas* from the isles of Sunda constantly differ in several characters from those of Bengal and the Philippine Islands. *Tortrix rufa* from the Celebes is distinguishable from individuals of the same species from Bengal and Java, by the uniform tint of the back, and by two small spots upon the occiput. *Calamar oligodon* of Java exhibits in Sumatra a difference in the dorsal tinting, and forms in Ceylon and the Philippine Islands a third local variety of great beauty. Analogous differences exist between the individuals of *Coronella baliodeira* of Java and Sumatra. *Lycodon Hebe* of Java is smaller in size, and not so pale in colour, as that same species in Bengal, while those from Timor are still more diminutive, and of darker hue. The

Ophidian
Reptiles.

Ophidian
Reptiles.

beautiful *Coluber melanurus* inhabits Java, Sumatra, and the Celebes; but the individuals from the last-named locality have the nape of the neck constantly adorned by an angular black mark. *Herpetodryas oxycephalus* is of a beautiful grass-green colour in Java; but this pure tint becomes embrowned in Borneo, and in Celebes appears almost black upon the dorsal region. *Dendrophis neta* inhabits almost all the intertropical countries of the Old World, from Senegal to New Guinea, but varies considerably at distant points of such a vast and surprising distribution. *Dryiophis nasuta* of Bengal and the Mariannas has in Java the abdomen rayed with yellow. *Dryiophis prasina*, common in the isles of Sunda, exhibits a local variety in the Celebes; and *Tropidonotus quincunciatus*, a species widely spread through India, has in Java the spots confluent, so that the dorsal portion seems rayed with black. *Trop. chrysargos* of Sumatra bears a different aspect from that species in the Celebes, while both vary from the individuals found in Java. *Homalopsis Schneideri*, which is spread from India to New Guinea, exhibits several varieties in different regions. The great *Python bivittatus* occurs in China, the isles of Sunda, both the Indian peninsulas, and Ceylon, and is, moreover, distributed across Africa as far as Senegambia. In this vast extent of territory it exhibits some considerable variations, which, when the extreme differences merely are regarded, and the intermediate links kept out of view, have caused it to be described, in its different aspects, as distinct species, all however referable, in Mr Schlegel's opinion, to one and the same. *Elaps furcatus* and *bivirgatus* exhibit a different distribution of colours in Sumatra from what they do in Java; but it may be stated as a general fact, that almost all the known serpents of the former island have been found also in the latter. Indeed a considerable number of these insular Ophidians occur likewise both in Hindustan and Bengal.

It is a singular circumstance, that the two most remarkable species of the genus *Trigonocephalus* (*Trig. puniceus* and *rhodostoma*) have hitherto been observed only in Java; while *Trig. viridis*, so common in India, Bengal, Sumatra, and Timor, does not occur in the first-named island. The genus *Bungarus*, on the other hand, which inhabits Ceylon, Hindustan, and Bengal, does not occur in any other of the great eastern islands, except Java. In the Celebes we find many peculiar forms of animal life, combined with others well known elsewhere. Among the serpents we find there a beautiful species of *Herpetodryas* (*Herp. dipsas*), and *Dipsas irregularis*, which also occurs in Amboyna. Several species are absolutely the same as those of Java and Sumatra, although a few form permanent local varieties, which exhibit some slight disparities of colour. Such are *Tortrix rufa*, *Coluber melanurus*, *Herpetodryas oxycephalus*, *Dryiophis prasina*, *Dipsas dendrophilus*, and *Tropidonotus chrysargus*. Of the Moluccas our knowledge is extremely slight, being confined chiefly to the island of Amboyna. We there find three or four serpents, likewise known as Javanese species; but it does not appear that the isles of Sunda produce *Lycodon modestus*, *Boa constrictor*, *Dendrophis rhodopleuron*, or *Python amethystinus*. Timor is in some measure intermediate in its productions between Java and the Moluccas. Its *Python* is perhaps different from that of Amboyna, and it produces a singular *Homalopsis* (*H. leucobalia*). *Lycodon Hebe* is there of a deeper tint than in Java; and *Coluber radiatus* is represented in Timor by *Col. subradiatus*,—a species analogous, but not the same. New Guinea and the adjacent islands produce several new species. We know little of the reptiles of the Philippines, though a few have been collected in the environs of Manila, in the island of Luçon; and these clearly establish the curious fact, that the species of that island bear a strong analogy to those of Ceylon,—not a few being identical. The *Naja* of the Philippines belongs to the ordinary variety

of *N. tripudians*, as it occurs in India, and which always differs in some measure from the same species from the isles of Sunda.

Ophidian
Reptiles.

The vast insular continent of New Holland is as yet but slightly known, most of its ascertained productions having been sent only from a few limited localities; but the anomalous and extraordinary character of its productions may even now be fairly inferred. The snakes seem peculiar, and almost all belong to the venomous division. No water species have as yet been seen there. It has already been observed, that the innumerable islands of the great Pacific Ocean are believed to be unproductive of serpents. The Mariannas, however, form an exception to this general rule, and Dampier mentions green serpents as inhabitants of the Gallipagos.

A few brief notices of the serpents of the New World may terminate the geographical department of our subject. On comparing the species of the two great continents of America with each other, we observe some interesting parallels. The rattle-snake, *Crotalus horridus*, so common over a large extent of South America, is represented in the northern territories by *Crot. durissus*, as is *Coronella venustissima* by *Cor. coccinea*. This kind of comparison, however, applies but to a few species, for the majority of kinds produced by one of the continents differ from those of the other. Thus, the genera *Tortrix*, *Dipsas*, *Dendrophis*, *Boa*, have as yet been found only in South America, or as far north as the Antilles, while *Tropidonotus*, on the contrary, is not found in the southern continent, though frequent in the northern, from which it likewise extends to parts of the West Indies. A small number, however, of southern species are found also in North America, such as *Calamaria melanocephala*, *Lycodon clelia*, *Coronella cobella*, *Herpetodryas cursor*, *Dryiophis Catesbyi*, *Elaps corallinus*, *Homalopsis carinicauda*; while in like manner *Heterodon platyrhinus*, and *Herpetodryas æstivus*, which may be regarded rather as northern species, have been ascertained to inhabit Brazil. The following species of North American reptiles also inhabit the Antilles; *Calamaria striatula*, *Coronella coccinea*, *Heterodon platyrhinus*, *Coluber constrictor*, *Herpetodryas æstivus* and *cursor*, *Tropidonotus bipunctatus*, *fasciatus*, and *serriata*. Those next named also occur in the Antilles, although their proper country is South America; *Calamaria melanocephala*, *Coronella reginae*, *Lycodon clelia*, *Dendrophis liocercus*, *Dryiophis Catesbyi* and *aurata*, *Dipsas annulata*, *Homalopsis angulata*, *Boa constrictor* and *conchria*, and *Elaps corallinus*. The species peculiar to these West Indian islands are very few in number, the most characteristic being *Psammophis Antillensis*, *Trigonocephalus lanceolatus*, *Dendrophis Catesbyi*, and *Boa melanura*. On comparing the snakes of Guiana with those of Brazil, we find many species common to both countries, several, however, forming local varieties more or less distinct, as in the cases of *Herpetodryas lineatus* and *Olfersii*, *Coluber poecilotoma*, &c. Certain species are peculiar to one or other of the countries above named,—for example, *Calamaria badiæ*, *Xenodon typhlus*, *Coluber corans*, *Herpetodryas Boddaertii*, *Dendrophis aurata*, *Dryiophis Catesbyi* and *argentea*, *Homalopsis plicatilis*, *Elaps lemniscatus* and *Surinamensis*, &c. have never been seen except in Guiana; while *Calamaria Blumi*, *Coronella Merremi*, *Xenodon Scholtzi* and *rhinostoma*, *Lycodon formosus*, *Herpetodryas serrii*, *Homalopsis carinicauda* and *Martii*, are found only in Brazil. Other species, again, appear as it were to represent each other in these parts of South America, so that we may place in parallel, *Coronella venustissima*, *Dipsas Mikani*, *Wegeli*, *leucocephala*, and *Nattereri*, and *Trigonocephalus Javanica*, of Brazil, with *Coronella venusta*, *Dipsas nebulata*, *Catesbyi*, *macrorhina*, *punctatissima*, and *Trigonocephalus atrox* of Guiana. The other parts of South America are too little known to admit of any detailed comparison; but it

Ophidian
Reptiles

may be observed, that of the species discovered in Chili, several are entirely new, and distinct from such as exist on this side the Cordilleras.¹

Notwithstanding the interest of the subject, we must now bring our general observations to a close, and proceed with a brief systematic sketch of the principal genera and species, referring the reader to M. Schlegel's work (and to those of the other Erpetologists here quoted) for more minute details. In conformity with the views of the author just named, we preserve the ancient subdivision of venomous and non-venomous kinds. The constant character of the former consists in being provided with a gland of a cellular structure, which secretes a very deleterious poison. Maxillary teeth, called fangs, of much greater length than the others, hollow interiorly, and furnished with openings at either extremity, for the entrance and exit of the poison, are the potent weapons with which these insidious reptiles inflict their fatal wounds. It is difficult, if not impossible, to assign to these serpents any certain character of external distinction, although there is something in their general aspect which points them out, even to the uninitiated, as dangerous neighbours. Their natural habits also offer this distinction, that the venomous kinds are almost always either terrestrial or marine, although *Trig. viridis* is slightly arboreal, and certain species of *Naja* occasionally occur in fresh water. But the colubriiform venomous kinds so greatly resemble the innocent species, that professed naturalists have sometimes combined them with each other. Their most common characters consist in a thickish rounded muzzle, and a short, thick, conical tail. The marine serpents may be recognised by their flattened tails.

The constitution of the following families bears relation rather to the habits of life than the organic structure of the species they respectively contain. We follow the classification of M. Schlegel.

FIRST PRIMARY DIVISION. NON-VENOMOUS SERPENTS.

Family I.—Burrowing Serpents.

Genus *TORTRIX*. Body cylindrical, of nearly equal dimensions throughout; head small, obtuse, and covered by imperfectly developed plates; eyes small; nostrils narrow; gape not widely cleft; teeth short and conical; tail short. (Plate V., fig. 6.)

The species of this genus (which in M. Schlegel's work includes also *Eryx* and *Xenopeltis* of other authors) inhabit the warmer countries of both the Old and New World, preferring dry and sandy districts, in which they form narrow excavations. *T. eryx* occurs over a vast extent of territory, from Egypt to Hindustan, and is met with in the southern parts of Europe. The ground colour of the dorsal region is a beautiful red with numerous confluent spots, and bands of blackish brown; the under parts are yellow, the whole covered by small scales. The muzzle is obliquely truncated at the end. Length about two and a half feet. Abdominal plates 195, caudal twenty. Six other species are known, of which *T. scytale* is American, and, of all undoubtedly Ophidian reptiles, makes the nearest approach to those ambiguous genera *Typhlops* and *Amphisbæna*.²

Family II.—Worm-like Serpents.

Genus *CALAMARIA*. Body small and cylindrical, terminated by a short conical tail. Head uniform with the body. Plates in the muzzle few in number.

The majority of the genus have the lower surface of a fine vermilion hue, a colour frequent among reptiles which

inhabit low and moist abodes. They seldom exceed a foot in length, and are found in both the Americas, in Africa, Southern Asia, New Holland, and the Indian Archipelago. There are eighteen described species, of which one of the most curious is *Cal. lumbricoidea* of Boié.³ Its body, though sometimes several feet long, does not exceed the thickness of a swan's quill. The colour is blackish-blue above, bluish below, with blackish spots, and a yellow ray along the sides. The scales are smooth, square, and disposed in thirteen rows. Abdominal plates from 190 to 217, caudal from sixteen to twenty-three. Eighteen species are known.

Family III.—Terrestrial Serpents.

Genus *CORONELLA*. Body somewhat pentagonal, thickening towards the centre. Head distinguishable from the neck, sometimes very broad at the base, depressed, the muzzle short, obtuse, and slightly truncated. Scales smooth, and disposed in from seventeen to nineteen longitudinal rows. Abdominal and caudal plates about 180 + 40.

The species of this genus are very alert in their movements, and defend themselves, when attacked, with great energy and perseverance. They are dispersed over almost all parts of the world (preferring plains and humid places), but have not as yet been observed in Japan or New Holland, and are rather rare in Asia. Specimens from South America are very frequent in collections. *Cor. laevis* is a well-known European species, which occurs in France, Germany, Switzerland, Italy, and, from Sparrmann's description, appears to be among the number of the few Ophidians which inhabit Sweden.⁴ It is of a shining bay colour, ornamented by irregular black marks, which form a peculiar design upon the head. The under surface is yellowish, marked with square black spots. There are twenty-one rows of scales, and the plates are 175 + 55. This species is viviparous, that is, the young are hatched within the body of the mother. When attacked, it attempts to escape with great celerity, and when foiled in that intention, it fights with energy, bites furiously, and will scarcely allow itself to be taken alive. It cannot be lifted by the end of the tail (at least with impunity), as many serpents may, as it possesses the power of bending its body upwards, and wounding the hand of its captor. However, its bite, though disagreeable, is in no way dangerous. It is an excellent swimmer, but does not enter the water willingly. It is very fond of mice. About fourteen other species are known to naturalists.

Genus *XENODON*. General form heavy, head broad, muzzle short and truncated, body thick, abdomen flattened. Upper jaws provided posteriorly with a solid, elongated, compressed tooth. Scales smooth, and dispersed in rather oblique ranges, especially on the neck, which is capable of expansion. Plates of the head short and broad.

Of this genus the species are eight in number, and of these the individuals are by no means abundant. They are of large size, sometimes measuring from three to four feet in length, and, being thick in proportion, present a somewhat formidable aspect. They are usually characterized by a grayish-blue tint, and occur chiefly in Java and intertropical America. None have been as yet found in Africa or New Holland, but *Xen. Michaelles* inhabits the south of France and Spain.⁵ This species is distinguished by its short conical head, terminated by a prominent rostral plate. It has twenty-seven rows of scales, and 216 + 60 plates.

Genus *HETERODON*. Head not very distinguishable from the general form, which is slightly pentagonal, and almost of equal thickness throughout. Abdomen somewhat angular, and narrower than in *Xenodon*. Tail very short, and furnished beneath with divided plates. Rostral plate al-

Non-venomous
Serpents.

ways prominent, sometimes prolonged into a small upturned trunk. Three species are known.

All the species are natives of the New World. The prevailing colour is red, ringed or spotted by a deeper hue. Their manners are unknown, but it is presumed that they inhabit a dry and sandy soil. We shall here name only the harlequin snake of America (*Het. coccineus*), which inhabits Louisiana and the southern states.¹ The ground colour is a bright yellow, tending more or less to brown upon the back, which is adorned with above twenty broad round or oval spots, of a purplish-red colour, bordered with black. Its brilliant tints are effaced soon after death. "This beautiful snake," says M. Audubon, alluding, we believe, to our present species, "is rather rare in the United States, where I have observed it only in the south. It glides through the grass with ease, and ascends to the tops of bushes, and among the branches of fallen trees, to bask in the sun. Children are fond of catching it on account of its beauty. It feeds principally on insects, such as flies, and small Coleoptera."² This seems the species described by Herrera in his History of the West Indies, as inhabiting Mexico and the Floridas, where it is known by the name of *Madre de Hormigas*, on account of its frequenting the society of ants.

Genus LYCODON. Form usually thin, sometimes extremely slender. Anterior maxillary teeth longer than the others. Vertical and anterior frontal plates small and shortened, the occipitals rather long.

The species inhabit both the Old and New World. The prevailing tint is of an earthy hue, passing more or less into brownish or ochry-yellow, the majority of species being ornamented by a collar of a clearer colour. Several kinds are ringed with black, white, and red. The abdominal plates usually amount to 200, the caudal vary from fifty to a hundred. We know little of the habits of these reptiles, of which above a dozen species have been collected in different parts of the intertropical world.

Genus COLUBER. This genus, as originally established by Linnæus, contained all the Ophidian reptiles with subdivided caudal plates. The venomous kinds were afterwards removed, and the genus itself partitioned into several groups; but even then the genus Coluber properly so called continued to contain a vast amount of species. MM. Boie and Schlegel restricted it still farther; and although it is difficult to apply the distinctive notes of these writers, the genus is natural in itself, when we seek to recognise it rather by the general bearing and physiognomy of the species, than by means of isolated characters.

It contains all those innocuous serpents of considerable size, which hold, as it were, by the form and proportion of their particular parts, a central position among the other Ophidians. Their bodies, less contracted than those of the fresh-water kinds, are yet by no means so slender as those of the arboreal species. Their head is not so lengthened as that of the latter, but is less broad than that of the aquatic sorts. The tail, modified in accordance with the nature of the species, varies in its form, as these resemble or recede from the conterminous groups in their mode of life. It is thus that certain species of the genus Coluber are closely connected with *Tropidonotus*, or even *Holmopsis*, while others are linked with *Herpetodryas*, *Psanmophis*, *Coronella*, or *Xenodon*. The muzzle is usually broad, thick, rounded, rather short, the nostrils lateral, open, and oblong. The head is always laterally angular, from whence results the lateral position of the eyes, of which the pupil is orbicular in form. The body varies in proportional thickness in the different species, but is usually compressed, and slightly

pentagonal. The abdomen is generally broad, convex, rarely angular, and is covered by numerous plates, more closely set together than in other serpents, and sometimes amounting to nearly 300. The tail is almost always cylindrical and pointed, generally of medium length, rarely slender and elongated, occasionally short and conic, its inferior portion furnished with divided plates. 12 sp. are known.

Almost all the countries of the earth, of which the nature of the soil and climate is not altogether opposed to the existence of the Ophidian order, are inhabited by the genus Coluber. Only a single species, however, has been found in Southern Africa, and not one has yet occurred in New Holland. Their habits are what may be termed terrestrial, that is, they rarely enter water of their own accord, although several climb among shrubs and bushes with some celerity in search of prey. Several kinds occur in Europe, and those from intertropical countries measure in some instances from seven to eight feet. They are rarely adorned with brilliant colours, brown being the prevailing hue. Of some the markings are uniform, while others are spotted or longitudinally rayed. Of the European species, one of the best known and most extensively distributed is *Col. Æsculapii*, which sometimes attains to the length of from four to five feet. The colour of the upper parts is olive-brown, beneath yellowish, or marbled with gray, with a paler collar. Abdominal plates 228, caudal seventy-nine.³ We have notes on the history of this species from MM. Host and Lenz. It is described as being extremely active in its movements, climbing trees with facility, but avoiding contact with water. It is oviparous, and feeds on lizards, frogs, and small birds, but takes no nourishment in captivity. When attacked, it defends itself with great determination; but when captured, becomes tame in a few days. In the museum of Vienna, several specimens of this Æsculapian snake are preserved alive; and their manners are so gentle that children make playthings of them, and handle them for hours at pleasure.

The ancient Greeks adored the god of medicine in various places under diverse forms, but frequently in the guise of a serpent, as an emblem of sagacity, and an animal endowed with so many sanatory qualities, that several Hellenic peoples regarded the creature itself as the very Deity. It was especially so with the inhabitants of Epidaurus (a flourishing city of Peloponnesus), who in a sacred grove, the favourite abode of serpents, erected a magnificent temple in honour of these by us abhorred reptiles. The Roman people, when terrified by a great pestilence, which ravaged the capital (in their year 461), sent an embassy to Epidaurus in search of this imaginary god, whom they might have found in sufficient abundance near at hand. They entertained these shmy deities in the island formed by the Tiber, and where we may still see their figure sculptured in marble in the gardens of St Bartholomew.⁴ Chandler tells us, in his Travels, that the environs of Epidaurus still abound in harmless serpents.

The only other species we shall here notice is *Coluber quater-radiatus*, remarkable as being the largest of the Ophidian reptiles of Europe. According to Metaxa (in his *Monograph* of the Serpents of the Environs of Rome), it sometimes attains the length of seven feet. It occurs in Italy, the south of France and Spain, Dalmatia, Hungary, &c. Its prevailing colour is an ochry-yellow passing into brown, and somewhat deeper on the under surface. Two lines of darker brown run along the flanks, and a blackish line passes from the eye to the corner of the mouth. This species, in spite of its great size and formidable aspect, is

Non-venomous
Serpents.

extremely gentle in its manners, and does not attempt to bite even when seized in its native haunts. It is very common in the fields near Tivoli, but is usually found on hill-sides. There is a passage in Pliny¹ which relates that the Boas of Italy sometimes attain to so great a size that the entire body of an infant was found in the interior of one slain during the reign of the Emperor Claudius. The species just noticed is certainly the largest of all the Roman serpents, but its natural attributes in no way favour the reception of this preposterous story.² The largest species of the genus is *Coluber coraus* of Surinam. There are twenty-seven different species described by M. Schlegel.

Genus HERPETODRYAS. This genus was established by the late M. Boié for the reception of certain species of Coluber (*Col. carinatus*, &c.), which combine the aspect and physiognomy of the preceding genus (to which they are closely allied) with the lengthened form and much of the habits of the arboreal serpents. Their colours are usually of a uniform greenish hue, sometimes passing into brown, or occasionally longitudinally rayed. The tail is generally long and slender, a character which, combined with the narrow and very angular abdomen, announces their arboreal disposition. Their manners are wild and distrustful, and they inhabit the warmer regions of both the Old and New World, with the exceptions, so far as yet known, of Africa and New Holland. We shall here name only *Herp. carinatus*, a Brazilian species, also common in Surinam. It is remarkable for having two central rows of dorsal scales, so that the total number of rows forms an equal number, a character unique in the Ophidian order. It varies greatly in its external markings.³ Schlegel describes nineteen species.

Genus PSAMMOPHIS. This little group may also be regarded as a dismemberment from Coluber, and brings us into still closer contact with the genuine tree-serpents. They offer an anomaly in their dentition, in as far as their posterior teeth, and those of the centre, are usually longer than the others, and furrowed. The head is elongated, the vertical plate very narrow. Some have the body thin and long drawn out, while others are more compact like Coluber. The species occur in India, Africa, and America; and *Psam. lacertina* is an European example well known in Dalmatia.⁴ They all prefer sandy soils, and prey chiefly upon Saurian reptiles. Green and brown are the prevailing colours, although several are longitudinally rayed, or have the head adorned by linear figures. Schlegel mentions eight species.

Family IV.—Arboreal or Tree-Serpents.

The members of this family are characteristic of the great forests of the tropical countries of Asia and America. They are rare in Africa, still more so in New Holland, and Europe produces only a few anomalous species. Their form is in general extremely elongated, they pass the greater portion of their time in trees and bushes, and prey both on birds and lizards.

Genus DENDROPHIS. Body compressed; abdomen (and sometimes the tail) angular, and furnished with very broad plates; scales narrow and elongated. Tail very slender. Head lengthened. Eye large, the pupil orbicular. (See Plate IV., fig. 5.)

These reptiles inhabit both the western and eastern world, but are rare in New Holland, and unknown in Europe. They climb trees with great facility, and are extremely quick in their general movements. They are frequently adorned by lively colours. Nearly a dozen species are known to naturalists. Schlegel has ten species.

Genus DRYIOPHIS. Muzzle slender and projecting. General form greatly elongated, the body compressed, the abdomen convex. Eye of moderate size.

Non-venomous
Serpents.

The species of this genus are among the most remarkable of the innocuous serpents, their shape being so extraordinarily lengthened out, that many measure nearly five feet in length, and are yet no thicker than the little finger. Hence their Anglo-American name of coach-whip snakes, of one of which, first described by Catesby, it was absurdly believed by the Indians, "that it will by a jerk of its tail separate a man in two parts."⁵ The tail, of extreme slenderness, always measures half the length of the whole body; and the muzzle is often drawn out in the form of a pointed proboscis. These reptiles inhabit the torrid zone, or the countries near the tropics, in Asia and the two Americas. Although unknown in the continent of Africa, a species (*D. langaha*) occurs in Madagascar. The genus admits of a geographical division,—those of the ancient continent being characterized by grooved maxillary teeth, and the pupil of the eye elongated horizontally, while such as inhabit America have the teeth less developed, and the pupil orbicular. We may briefly notice *Dryiophis nasuta* (the *Passeriki* of Russel),⁶ a remarkable species of a beautiful grass-green colour above, the lower surface paler, and marbled with red. A white or yellow ray extends from behind the eye to the commissure of the lips, and another very distinct one passes along each side of the abdomen and tail. The muzzle is very sharp, and is terminated by a moveable fleshy appendage. (See Plate IV., figs. 7 and 9.) This kind occurs over a great extent of India and the great eastern islands, and is frequent in the environs of Vizagapatam. It lives in trees, and its manners are described as being even ferocious. Its bite, however, is attended by no other bad consequences than the pain of the wound; but the common people deem it dangerous, as directing its attacks chiefly at the eyes of the passers by. There is an Indian whip-snake (probably not of this genus) common in the Concan, where it is described as concealing itself among the foliage of trees, from which it darts at cattle grazing below, generally also aiming at the eye. A bull which was thus wounded at Dazagon tore up the ground with extreme fury, and died in half an hour, foaming at the mouth. This habit of the reptile is truly singular,—for it seems to proceed neither from resentment nor from fear, nor yet from the impulse of appetite, but seems, "more than any other known fact in natural history, to partake of that frightful and mysterious principle of evil, which tempts our own species so often to tyrannize for mere wantonness of power."⁷

The species already named as a native of Madagascar, *Dryiophis langaha*, Schlegel, partakes of those anomalous attributes which characterize so many animal products of that extraordinary island. It measures between two and three feet in length, and is of a beautiful reddish-brown colour above, the under surface being of a deep though lively yellow, spotted with brown, especially beneath the tail; but its most peculiar character is seen in the muzzle, which is prolonged into a fleshy appendage of half an inch in length, covered with small scales, and of variable form, being in some cases sharp-pointed, in others compressed and enlarged, or leaf-shaped. This curious reptile seems to have been first (we believe inaccurately) described by M. Bruguières,⁸ and has since been banded about through various genera.⁹ It is classed by M. Schlegel (we presume after due examination),¹⁰ among the innocuous, that is, the non-venomous kinds,—although the natives of Madagascar

Non-venomous
Serpents.

are said to hold it in great dread, from the belief of its being a highly poisonous species.¹ Schlegel has 7 species. Genus *DIPSAS*. Head thick, broad, obtuse; the body vigorous, but much compressed. Pupil of the eye usually vertical. (Plate V., fig. 7.)

This genus comprises all those tree-serpents which, resembling the Colubers (and so far differing from the two preceding genera) in the bulkier proportion of their parts, are distinguished by their compressed bodies and more slender tails. Both the size and colours differ greatly according to the species, some of which do not measure more than fourteen inches, while others extend to five or six feet. South America and the East Indies are their characteristic countries, although a somewhat anomalous species is found in Egypt and Dalmatia. The genuine *Dipsas* dwell habitually in trees, concealing themselves amid dense foliage, from whence they dart upon their unsuspecting prey. The largest species known to naturalists is *Dip. dendrophila*, a Javanese reptile, which sometimes measures seven feet in length. The ground-colour is a beautiful lustrous black, with steel-blue reflections, paler on the under surface; and the body is encircled by from forty-five to fifty transverse narrow bands of a fine golden yellow.² *Dip. fallax* is, we presume, the sole European species,—if the reptile so named really pertains to our present genus.³ Its habits offer great disparity, at least M. Cantraine found it in Dalmatia in the month of December, creeping slowly among the ruins of an ancient castle. It had previously been found in the Levant by Olivier, and was more recently observed in the Morea by M. Bory St Vincent. Fleischman informs us that it lives under stones, stirs abroad only in the early morning and towards evening, avoids water, and feeds on insects, lizards, and mice. Twenty-five species of this genus are described by M. Schlegel.

Family V.—Fresh-water Serpents.

The members of this group are more or less allied to Coluber in their organization. They inhabit the water, or at least frequently enter into that element, and prefer the banks of rivers and the shores of lakes to situations more remote from moisture. It does not follow that all snakes endowed with analogous instincts and manners belong to this group, because the majority of the Boas, and almost all the Colubers, nearly correspond in their habits of life, and are yet very dissimilar in their structure. In this family there are combined those serpents which, having many mutual relations in their form and physiognomy, constitute a very natural assemblage, though by no means distantly separated from all other subdivisions. It is composed of two genera, of which the first exhibits, with few exceptions, nothing remarkable in its organization,—while the second is characterized by several singular features.

Genus *TROPIDONOTUS*. Head broad, body rather bulky, abdomen broad and convex, tail short.

The majority of this genus inhabit Asia, especially the Indian Archipelago. Southern Africa produces only a single species; Europe two, which occur on both sides of the Mediterranean basin. The same restricted number is found in Japan, and several are native to North America. None is known to inhabit either South America or New Holland. Certain species are widely distributed, while others are confined within narrow limits. They usually occur along the shady, wooded banks of lakes and rivers, where they prey on frogs and fishes. They swim with great dexterity, and are capable of continuing for a length of time beneath the surface. Although they can both creep

and climb with considerable swiftness, they usually prefer to escape from threatened danger by plunging into water. Many species never remove from the close vicinity of that element; others inhabit plains subject to inundation; and a few are found to dwell in moist umbrageous forests, even on the sides and towards the summits of high mountains. Certain species are gregarious; while some are solitary, dwelling in the deserted holes of small quadrupeds. Such as inhabit temperate climates fall into a lethargic state in winter. The whole are oviparous; but the eggs of many, even when newly laid, contain young in a state of considerable advancement. Schlegel describes nineteen species.

The first species we shall notice is *Tropidonotus natrix* (*Coluber natrix*, Linn., *Natrix torquata*, Ray), the best-known and most generally-diffused of European serpents, and one of the few which inhabit the cold and cloudy clime of Britain. We have exhibited its osteology on Plate V., fig. 2. It is subject to great variation of colour, but the prevailing tint is a pale ashy-blue tinged with green, and relieved by a series of black spots or bands. The undersurface is dusky blue, with mottlings of yellowish white. The collar is white or yellow, bordered posteriorly by deep black; and the plates of the head are extremely regular in their form. The length ranges from two and a half to four, or occasionally five feet. The female is always the larger. This reptile has been studied and described by a host of European writers. It is not characterized by any wildness or ferocity, is easily tamed, and rarely bites even when seized. “Il m’est cependant arrivé,” says M. Schlegel, “qu’étant encore très-jeune, et m’étant approché du bord d’un bois, où une société nombreuse de ces serpents s’était établie pour faire leur ponte, un *Tropidonote* d’une taille énorme m’attaqua avec fureur, tandis que plusieurs autres s’échappaient dans les trous dont la terre était percée.”⁴ The ringed snake, as our present species is generally named, prefers to take possession of the subterranean dwelling of a mouse or mole to commencing an excavation for itself. Being fond of warmth and shelter, it often approaches human habitations, and readily lays its eggs in dunghills. Yet it is often met with in the remotest wilds, or in thick umbrageous forests, and sometimes at a height of several thousand feet above the level of the sea. But on the whole it prefers the vicinity of tranquil waters, where it dives frequently in search of fishes, as well as of frogs and other batrachian reptiles. Although it possesses the power of remaining under water for nearly half an hour, it is not organized for a continued abode in that element; and when frequently forced from shore, its swimming powers become exhausted, and it is “found drowned.” It is extremely voracious, and will swallow a great number of frogs at a meal. It hibernates, in cold and temperate countries, from the month of October or November, seeking profounder excavations, where frost can scarcely enter. It leaves its retreat in March or April, according to the region it inhabits, and casts its skin once a month till the end of August. In that month also it lays its eggs, to the number of two dozen or more. As the species pairs in April, it follows that these eggs take five months to be developed in the oviducts, though they are hatched in about three weeks after deposition. Their form is oval, and they measure about an inch and three lines in length. The young, when first visible, measure from six to eight inches. This species abounds over all France and Germany. It does not inhabit the maritime parts of Holland, but is common in Guelderland and the province of Drenthe. It is well known in Italy, Sicily, and Sardinia, as well as in Denmark, Sweden, and Norway, and extends over a great portion of temperate

Serpents.

Asia, as far as Lake Baikal. It is a common species in England, where it occurs in woods and hedges, as well as in marshes. Mr Jenyns informs us, that it is particularly abundant in the fens of Cambridgeshire, where it sometimes attains a great size.¹ We shall merely add, that it is eaten in several continental countries. *Col. viperinus*, another European species, pertains to this genus; as do also a considerable amount of exotic kinds, which we cannot here so much as name.

Genus HOMALOPSIS. Body bulky, head very thick, muzzle short and rounded; eyes and nostrils small, and opening upwards; form usually cylindrical, sometimes slightly compressed; abdomen broad and convex; tail short, conical, robust.

This genus inhabits the great fresh waters of the inter-tropical countries both of Asia and America, although it seems less extended than the preceding, being seldom seen beyond the tropics. A Bengal species occurs also in Java, and a few are found identically the same in both the Americas. The majority attain a considerable size; but though as thick as a man's arm, they rarely exceed the length of four feet. Their heavy inelegant forms, small insidious eyes, and large gaping mouths, confer upon them a peculiar and repelling physiognomy; yet they are quite innocuous, in spite of the malignity of their aspect, a proof that we should never judge from appearance. These are the most truly aquatic of all the fresh-water serpents, passing almost their entire lives submerged, and feeding chiefly on fish. They are endowed with great muscular strength and strong powers of locomotion in their favourite element. Their colours are usually dark and lugubrious,—a schistose gray, brown, olive, or a blackish hue prevailing over the upper surface; while a yellower tint, with large square spots, is frequent on the abdominal region. We are acquainted with few details regarding their habits of life; and the species are rare in collections, probably in consequence of their fish-like activity in the water rendering their capture difficult. They are distributed over a variety of genera by different naturalists; and M. Schlegel describes fourteen species, among which are included *Hom. herpeton* (*Erpeton tentaculatus*, Lac.²), a serpent remarkable for two fleshy appendages covered with scales, which extend from the termination of the muzzle. (See Plate IV., fig. 4.) The abdominal plates are scarcely broader than the other scales, and each is surmounted by a couple of ridges. Its native country is unknown.

Family VI.—Boas.

This family, according to M. Schlegel's views, comprehends the greater number of those species which modern naturalists have comprised under the genera *Boa*, *Python*, and *Acrochordus*. It is one of the most natural of the entire order, and has been too often erroneously separated, merely on the consideration of a few unimportant characters. We here find species, some of them the largest of the Ophidian race, distinguished by a prehensile tail, and a body possessing the power of twisting itself around other bodies with great force and facility. The surface is encompassed by numerous small scales, which advance upon the head and encroach on the abdomen, so that the former part never exhibits the regularly-formed plates of the Colubers, while those of the latter are unusually narrow. The

vertical position of the nostrils and small-sized eyes announce a combination of aquatic with terrestrial habits of life. The first genus, that of *Boa* properly so called, is characterized by simple plates beneath the tail; the second, *Python*, peculiar to the ancient world, exhibits the sub-caudal plates divided, a supernumerary bone on the upper margin of the orbits, and intermaxillary teeth; the third, *Acrochordus*, is destitute of anal hooks, and has the surface entirely covered over by small granular unimbricated scales. All these generic groups have many characters in common, both in habits and organization, and we shall here point out a few of their generalities.

The term *Boa*, according to Pliny,³ is derived from *Bos*, because the young of these reptiles are wont to nourish themselves on cow's milk.⁴ We are farther informed by that credulous author, of the great *Boa* slain in the Vatican, within the abdomen of which was found an entire infant. Linnæus applied the name to all serpents provided with simple sub-caudal plates. It is obvious that his genus, founded on a character of such slight importance, while it excludes the *Pythons*, necessarily brings together several heterogeneous groups. The defect in the modern arrangement of these reptiles arises chiefly from the practice of viewing a single and often subordinate character, and ruling, as it were, the forms of nature in simple accordance with its absence or existence. We thus find the *Pythons* almost always separated from the *Boas*, and placed in the genus *Coluber*, while the *Acrochordi*, estranged from both, comprise two distinct genera, sometimes placed among venomous serpents, sometimes classed with the innocuous kinds. "Nos temps," says M. Schlegel, "fertiles en invasions de toute sorte, ont vu démembrer la famille des Boas en autant de divisions génériques que l'on en compte d'espèces, qui elles-mêmes sont multipliées sans le moindre fondement de vérité. Il n'est pas rare de voir la même espèce distribuée en deux ou trois genres différens, et ces genres placés au hasard parmi d'autres Couleuvres ou parmi les vipères." The opportunities enjoyed by the author just named, of studying the various species, has led him to the belief that these are much less numerous than generally supposed. He thinks that the majority of such as exist in nature are now in some measure known, and that they do not amount to more than fifteen, including *Acrochordus*. Various anomalies exist among the species when compared among each other. Some are spread over a vast tract of territory, while others are confined within narrow limits. They are all, however, inhabitants of countries either situate beneath the equator or near the tropics. They occur in both the Old and New World, but none is found in Europe, North America, or Japan. The South American species are frequent in collections; those of the (so-called) more ancient countries of the earth are rather rare. Some are oviparous, others produce their young alive. The *Boas* usually attain, in truth, to an enormous size, although their actual dimensions have been greatly exaggerated. Thus at the very name of *Boa constrictor* the imagination is filled "with folds voluminous and vast," although the species really so called scarcely ever exceeds ten or twelve feet in length. The largest Ophidian reptiles in the world are *Boa murina* and *Python Schneideri* and *bivittatus*; but it may be greatly doubted whether the first named, which is the most gigantic of all, ever exceeds twenty-five feet in these degenerate days, and we have no sufficient

Non-venomous
Serpents.

⁴ "Quant aux véritables serpents, il n'en est pas qui mâchent réellement, de même qu'il est évident qu'aucun ne peut sucer ou opérer le vide dans la bouche, et que, par conséquent, c'est un préjugé de croire que plusieurs de ces animaux, comme les Boas et les Couleuvres, puissent téter les vaches; outre l'absence des lèvres charnues, le défaut de voile du palais et de l'épiglotte, qui rendraient la succion impossible, il est évident que les crochets acérés et recourbés en arrière, qui garnissent leurs mâchoires et leur palais, s'accrocheraient comme des hameçons aux tétines des mammifères et qu'ils ne pourraient s'en détacher." (*Erp. Gén.* i. 135.)

Non-venomous
Serpents.

reason for supposing that it was ever any larger in former times.¹ The recitals of our travellers have been too often drawn, not from their own observation (by no means accurate at the best), but merely from the popular belief of ignorant and superstitious natives. The Pythons of the Old World seldom exceed from eighteen to twenty feet in length; and we can easily believe that one even of that extent being met by a benighted traveller in some lone-some forest glade, or murky meadow, might be afterwards described as something super-serpentine. Who in early life (how few at any period) ever caught a trout of two pounds or a pike of ten, without at least supposing that the one weighed four, the other fifteen? Yet who fears the innocuous finny race, and how greatly must doubt and dismay increase the seeming dimensions of a huge lugubrious reptile, weaving its way through some "wild wood, dingle or bushy dell," and dimly seen in sombre twilight hours, by snatches of only four or five yards at a time? The same exaggeration prevails regarding both the size of their natural prey, and its mode of capture. The lamented Boié, who made numerous observations on the Pythons of Asiatic countries, states that they particularly attack only the smaller kinds of quadrupeds, although individuals of unusual size sometimes swallow a young pig, or that species of deer called muntjac. But the larger mammiferous animals, and the human race more especially, need entertain no reasonable expectation of attack; and Prince Neuwied confirms this statement of the lamented naturalist of Kiel, so far as concerns the great species of the New World, which prey chiefly on birds and reptiles.

Boas are said to be by no means difficult to tame. M. Dieperink of Paramaribo informed M. Schlegel that he was in the practice of keeping by him several different kinds of live Boas, all of which lived in perfect harmony, both among themselves and with other domestic animals. Professor Reindwardt, however, was witness at Java to a spectacle which proved that these great serpents are not always as merciful as they are strong. A native of the island having brought to the Baron Van Der Capellen a huge Python, and being desirous to make it leave a pannier in which it was contained, the monster rose upon him suddenly, and inflicted a severe wound, at once laying open the fore-arm throughout its entire extent. It may be as well, then, upon the whole, not to allow the serpents of this family to sleep at large in the bed-chambers of any other family where there are small children.

The members of our present group seize their prey suddenly by ambuscade, usually lying in wait for it in the vicinity of water. They fix upon it with their teeth, and then, if of tolerable size or strength, entwine their folds around it, pressing out the breath of life, or even bruising the body, and breaking the bones in pieces. To aid this act of butchery, some of the species are said to keep their tails twisted around a tree, to which they drag their reluctant victim,—making use at the same time of the hard and gnarled trunk to give a still stronger stringency to their dreadful coils, while the faint-hearted prey

Clamores simul horrendos ad sidera tollit.

Non-venomous
Serpents.

When the animal attacked is of smaller size, it is merely *mouthed*, always head foremost, covered with saliva to hasten putrefaction and aid deglutition, and afterwards swallowed at leisure. These gigantic reptiles are endowed with great muscular force, which, however, they rarely exercise in a state of captivity. They seem extremely lethargic when imported into Europe; many of them, if not gentle in their manners, at least cannot be induced to bite by any provocation; their movements are very slow, they rarely eat, and the majority indeed die after a few months' confinement, without having tasted food.

The following curious, and we doubt not accurate, account of the swallowing powers of one of the great Asiatic serpents, has been recorded by Mr Macleod. He calls the species *Boa constrictor*, which, as it was captured in Borneo, it could not be. It belonged, we presume, to the genus Python, and measured sixteen feet in length by about eighteen inches in circumference. We shall make no apology for the size of the ensuing extract, as it so clearly illustrates the peculiar manners and the mode of deglutition of these Boa-like serpents.

"The live stock for his use during the passage, consisting of six goats of the ordinary size, were sent with him on board, five being considered as a fair allowance for as many months. At an early period of the voyage we had an exhibition of his talent in the way of eating, which was publicly performed on the quarter-deck, upon which he was brought. The sliding door (of his cage) being opened, one of the goats was thrust in, and the door of the cage shut. The poor goat, as if instantly aware of all the horrors of its perilous situation, immediately began to utter the most piercing and distressing cries, butting instinctively at the same time with its head towards the serpent, in self-defence. The snake, which at first appeared scarcely to notice the poor animal, soon began to stir a little, and turning his head in the direction of the goat, he at length fixed a deadly and malignant eye on the trembling victim, whose agony and terror seemed to increase; for, previous to the snake seizing his prey, it shook in every limb, but still continuing its unavailing show of attack, by butting at the serpent, which now became sufficiently animated to prepare for the banquet. The first operation was that of darting out his forked tongue, and at the same time rearing a little his head; then suddenly seizing the goat by the fore leg with his mouth, and throwing it down, it was encircled in an instant in his horrid folds. So quick, indeed, and so instantaneous was the act, that it was impossible for the eye to follow the rapid convulsion of his elongated body. It was not a regular *screw-like* turn that was formed, but resembling rather a knot, one part of the body overlaying the other, as if to add weight to the muscular pressure, the more effectually to crush his object. During this time he continued to grasp with his fangs, though it appeared an unnecessary precaution, that part of the animal which he had first seized. The poor goat, in the mean time, continued its feeble and *half-stifled* cries for some minutes, but they soon became more and more faint, and at last it expired. The snake, however, retained it for a considerable time in his grasp after it was apparently motionless. He

¹ Unable as we are either to confirm or contradict, from personal experience, the reported observations of travellers regarding the supposed dimensions of these huge reptiles, we are under the necessity of stating the different opinions which prevail upon the subject, however irreconcilable these may sometimes seem with each other. The following quotation rather favours the idea of their great size and unexampled voracity. "In the Dutch colonies of the East Indies, André Cleyer purchased of the hunters of the country an enormous serpent, in the body of which he found a deer of middle age, altogether entire, with its skin and limbs. In another individual of the same species, also examined by the traveller, a wild he-goat was found, with its horns; and a third had evidently swallowed a porcupine with its quills. He adds, that a pregnant woman also became the prey of a reptile of the same genus in the island of Amboyna; and that this kind is sometimes kept for the purpose of attacking the buffaloes in the kingdom of Aracan, on the frontiers of Bengal. We need hardly be astonished at this, when Prince Maurice of Nassau-Siegen, one of the governors of Brazil, in the seventeenth century, assures us that he himself was an eye-witness of stags, and other equally voluminous mammifera, and even of a Dutch woman" (usually a considerable mammifer), "being devoured in this manner, in that region of South America where he commanded." Griffith's *Animal Kingdom*, ix. 295.

Non-venomous
Serpents.

then slowly and cautiously unfolded himself, till the goat fell dead from his monstrous embrace, when he began to prepare himself for swallowing it. Placing his mouth in front of the dead animal, he commenced by lubricating with his saliva that part of the goat; and then taking its muzzle into his mouth, which had, and indeed always has, the appearance of a raw, lacerated wound, he sucked it in as far as the horns would allow. These protuberances opposed some little difficulty, not so much from their extent, as from their points; however, they also in a very short time disappeared, that is to say, externally; but their progress was still to be traced very distinctly on the outside, threatening every moment to protrude through the skin. The victim had now descended as far as the shoulders; and it was an astonishing sight to observe the extraordinary action of the snake's muscles when stretched to such an unnatural extent,—an extent which must have utterly destroyed all muscular power in any animal that was not, like himself, endowed with very peculiar faculties of expansion and action at the same time. When his head and neck had no other appearance than that of a serpent's skin, stuffed almost to bursting, still the workings of the muscles were evident, and his power of suction, as it is erroneously called, unabated; it was, in fact, the effect of a contractile muscular power, assisted by two rows of strong, hooked teeth. With all this, he must be so formed as to be able to suspend, for a time, his respiration; for it is impossible to conceive that the process of breathing could be carried on while the mouth and throat were so completely stuffed and expanded by the body of the goat, and the lungs themselves (admitting the trachea to be ever so hard) compressed, as they must have been, by its passage downwards.

"The whole operation of completely gorging the goat occupied about two hours and twenty minutes; at the end of which time the tumefaction was confined to the middle part of the body, or stomach, the superior parts, which had been so much distended, having resumed their natural dimensions. He then coiled himself up again, and lay quietly in his usual torpid state for about three weeks or a month, when, his last meal appearing to be completely digested and dissolved, he was presented with another goat, which he killed and devoured with equal facility."¹

As the vessel, which was sailing from Batavia to England, approached the Cape of Good Hope, this gigantic reptile began to droop, as was at first supposed, from the increasing cold. It refused to kill some fowls which were presented, and died before reaching St Helena. On dissection, the coats of the stomach were found to be "excoriated and pierced by worms!" Nothing of either goat remained except a single horn. During a prior captivity of some months at Whidah, in the kingdom of Dahomey, Mr Macleod had enjoyed opportunities of observing snakes "double the size of the one just described." These killed their prey in the same manner; but from their superior bulk were capable of swallowing much larger animals than either goats or sheep. Governor Abson, who had resided for nearly forty years at Fort William, a settlement of the African Company, used to describe some desperate struggles which had taken place between these great serpents and various wild beasts, as well as smaller cattle. A negro herdsman was once seized by the thigh, but the monster, in attempting to entwine itself around him, got en-

Non-venomous
Serpents.

tangled by a tree, and the man being armed with a knife, had presence of mind to inflict several severe gashes on the neck and throat, which enabled him to disengage himself from the dreadful coils which were closing fast around him. But he remained lame for life, in consequence of the wound and heavy pressure inflicted by the jaws.

The natural colours, which are various in this family, disappear speedily after death. Some are brown upon a yellowish ground, others exhibit a uniformly greenish hue, red prevails among certain species, while a few are nearly black. Almost all are more or less spotted; and it has been observed that, unlike the smaller tribes of serpents, these markings continue equally, or rather more distinct, as the individual increases in years. The body of the Boas is thickest at the middle, tapers towards either end, and is always considerably compressed. The abdomen is broad, and slightly convex or keeled. The tail is shaped like the body, but is more slender, not very conical, and usually terminates in a blunted point. It is always prehensile, that is, possesses the power of rolling inwards upon itself, or forming convolutions around other bodies. The scales in general are rather small, and as they encroach considerably on the under surface, it follows that the abdominal plates are narrower than usual. There are sometimes from sixty to seventy ranges of scales, and about two hundred and fifty abdominal plates. The number of these, however, is greater in the Boas of the ancient world than among the American species, which moreover differ in several other respects; while the genus *Acrochordus* is distinguished from all its congeners by the small granular scales which clothe the entire surface, and of which a double series prevails along the median line of the abdomen, forming a kind of projecting ridge or keel.

The head of the Boas is always distinguishable from the trunk, being thick, rather lengthened, conical, depressed, and terminated by a muzzle for the most part elongated, and truncated at the point. The eyes are placed at some distance from the nostrils, and are lateral in the terrestrial species, of which the head is flattened above, and more or less angular on the sides; but the more aquatic kinds have the eyes rather vertical. These organs are always small in our present family, and, excepting *Acrochordus*, have the pupil horizontally elongated. The nostrils are broad, closely approached to the end of the muzzle, and in some are placed upon its summit. They open upwards in the genus just named, and assume a tubular form. All the species are provided with palatine teeth, nearly as much developed as the maxillary ones; but there are no intermaxillary teeth except among the Pythons. The glands of the head are less developed in this family than among the majority of Ophidian reptiles.

Genus BOA. No intermaxillary teeth. Space between the orbits formed solely by the frontals properly so called. Sub-caudal plates simple.² (See Plate IV., figs. 8–11.)

This restricted genus includes the largest of Ophidian reptiles, and although composed chiefly of South American snakes, it also contains three Asiatic species, which, though of much smaller size, cannot be regarded otherwise than as a geographical division.

Boa constrictor, Linn., is a middle-sized species, which rarely exceeds the length of ten or twelve feet.³ It is of a reddish tint, elegantly marked by irregular reticulations of

¹ Macleod's *Voyage of the Alceste*, p. 290.

² This is the prevailing character of these parts, although we find in this, as in many other cases, a difficulty in seizing upon single determinate features of constant application. Thus we sometimes meet with several divided plates in the sub-caudal region of these so-called Boas.

³ The true *B. constrictor* is often confounded with the more gigantic *B. murina*, and its dimensions have in consequence been greatly exaggerated. We doubt if any existing species ever attains to the alleged size of the so-called *B. constrictor*. Mr Swainson, however, who has travelled in South America, and is himself a zealous student of the facts of zoology, both as recorded in books and as existing in nature, states that the young individuals frequent in our menageries are mere pigmies in comparison to the

Non-venomous
Serpents.

brownish black, and other hues, and is subject to a great variety of aspect, so far as colour is concerned. It is, however, well characterized by the small smooth scales which cover both head and body, and of which there are sixty-seven rows. The head is heart-shaped, and the tail short. Abdominal plates 243, caudal fifty-eight. This species is native to the intertropical countries of South America, and not only have its size and voracity been greatly exaggerated, but many traits have been applied to it which truly belong only to the Pythons of the ancient continent. Thus the very name of *Devin*, bestowed upon it by Lacépède, is borrowed from what Bosman relates of the worship accorded by the negroes to certain African reptiles. It is met with in Surinam and Brazil, in woody districts, being sometimes seen suspended from the branch of a tree, sometimes concealed in the hollows of rocks, or beneath an ancient trunk. It is feared by no one, is often killed with a short walking-stick, and is commonly known by the name of *Jiboya*. It feeds on small and middle-sized mammalia, such as mice, rats, agoutis, pacas, and capybaras, as well as on various reptiles. A hunter, however, assured the Prince of Neuwied, that his dog on one occasion would have fallen a victim to a Boa of this species, had he not contrived to shoot it during the combat. The true constrictor does not enter the water. The Brazilians take it by means of gins, and employ its skin for making boots and saddle-cloths. They also use its fat. All engraved representations of this species, having been made from ill-prepared museum specimens, are worse than indifferent.¹

The rat-eating Boa, *B. murina*, Linn. (*B. Anaconda*, Daud.² *B. aquatica*, Neuw.³), is the largest Ophidian reptile of America, and probably the most gigantic of known species. It is distinguished in Brazil by the title of *Cucuruba*, and passes a great portion of its time in the water, either swimming about in various directions, or floating lazily with the current. It dives with great dexterity, can remain for a length of time beneath the surface, and is said to prey on fish as well as quadrupeds. It is tenacious of life, and is killed by the natives either with bow or musket in the water, or with sticks when met with on shore, where its movements are somewhat sluggish. Both its skin and fat are used for various purposes, and its flesh is eaten by the Botocudes. M. Fermin measured one which had attained the length of twenty-three and a half feet; and the Prince of Neuwied was assured by the natives that it is often much longer, although he himself never saw one above twenty feet. This species exhibits less varied markings than the preceding. The general hue of the upper parts is sooty brown, with two rows of orbicular blackish spots along the back. The under surface and sides are of an ochry yellow, the latter marked with a double row of irregular eye-shaped spots, which confound themselves with numerous squarer spots upon the belly. The nostrils are vertical, the eyes also directed upwards. The head is of

an elongated form, with a rounded muzzle. Abdominal plates 250, caudal sixty-six.

Non-venomous
Serpents.

The other species of this genus are *B. cenchria*, *canina* (Plate IV. figs. 8–11), *hortulana* from South America; *B. Dussumieri*, from a small island near the Mauritius; *B. carinata*, from the Moluccas and New Guinea; *B. conica*, from Bengal; and *B. melanura*, from the island of Cuba. Schlegel describes nine species.

Genus PYTHON. Several intermaxillary teeth. Upper portion of the orbit formed by a particular bone incased among the three frontals, and named super-orbital by Cuvier. Sub-caudal plates usually divided. Lips hollowed out in front. Plates of the head larger and more regular than in Boa. (See Plate IV., figs. 1 *b*, 1 *c*, and 3; and Plate V., fig. 5.)

This genus was established by M. Daudin for the reception of the great serpents of the ancient world. Brown, black, and yellow, are their prevailing colours. Certain of the species equal (some say exceed) the Boas of America in size, for example the *Ular-sawa* (*Python bivittatus*, Khul.—*Col. Javanicus*, Shaw). This species is of a yellowish tint, relieved by a pattern of broad alternate brown spots. The top of the head is margined by two rays of the ground colour. The flanks are variously adorned by black and white, and the under surface is marked by deep square spots. There are sixty-three ranges of smooth small scales, 270 abdominal and seventy caudal plates. This great reptile is spread, according to M. Schlegel, over a vast extent of territory, being known to occur from the western coast of Africa, over the whole of intertropical Asia, as far east as China and the island of Java. It is said to attain the length of twenty-five feet, and individuals of twenty feet in length have been seen and described by trustworthy naturalists. A fine specimen lived for some time in Holland, and was observed to be slow in its movements, mild in its temper, and never inclined to bite even when provoked. It was kept in a large box enveloped in woollen cloths, where it lay in continued tranquillity, and suffered itself to be drawn out for frequent exhibition without manifesting any signs of anger or impatience. We suspect that the senses of this, and of other large tropical snakes, are so far benumbed by the change of climate in Europe as to produce stupefaction rather than tameness. The specimen in question was presented with food every eight days, which, however, it often refused for several successive times. It was most easily excited to eat by the sight of a live rabbit, into the head of which it would fix its teeth, and then, placing it within a fold of its body, deprived it almost instantly of life. After the commission of this murder, it was in no hurry to swallow its victim, but sometimes licked it for a while, occasionally taking two or three hours to effect the final deglutition. This is supposed to be the *Pedda-poda* of Dr Russel, called rock-snake by the Anglo-Indians.⁴

We do not happen to know to what extent this or any

adults, "which have been often found to exceed forty feet in length" (*Cabinet Cyclopædia*, vol. cxvi. p. 143). Yet he does not state this as a result of observation, or as connected with his own knowledge as well as belief. A single specimen of such gigantic reptile would be the wonder of Europe, and would make a fortune for its owner. A Dutch friend of Mr Waterton's killed a Boa (he does not say of what species) twenty-two feet long, with a pair of stag's horns in its mouth. It had swallowed the stag, but could not swallow the horns (at which we are not much surprised), and so had to wait in patience with that uncomfortable mouthful till its stomach had digested the body, "and then the horns would drop out." It was in this expectant plight that the Dutchman found it, as he was going in his canoe up the river, and sent a ball through its head (*Wanderings in South America*, third edit. p. 209). The large serpent bagged by Mr Waterton, after "a sharp fray in the den, the rotten sticks flying on all sides, and each party struggling for superiority," measured rather more than fourteen feet in length. It was of the kind called *Conulacanara*, a rare species, and so much thicker in proportion to its length than any other snake of the forest, that an individual of the extent just stated "is as thick as a common Boa of twenty-four." Its jaws are so extensile, that Mr Waterton, after skinning his specimen, could easily get his head into its mouth.

¹ See Scheuchzer, *Biblia Sacra*, pl. 746, fig. 1:—Lacép. *Quadr. Ovip.* ii. pl. 16, fig. 1:—Daudin, *Reptiles*, v. pl. 92, fig. 1. There are various figures of our *B. constrictor* in Seba's *Thesaurus*, and from these Laurenti seems to have composed such species as *Constrictor formosissimus*, *Rex serpentum*, *diviniloquus*, and several others.

² *Reptiles*, v. 161, pl. 63.

³ Numerous nominal species have arisen from the superficial observance of different varieties of this Python. See Russel's *Serpents*, pl. 20, 23, 24, and 29; and Daudin's *Reptiles*, v. pl. 64, fig. 1, and pl. 59, fig. 4.

⁴ *Abbild.* livrais ii. pl. 6, and *Beitr.* p. 226.

Non-venomous
Serpents.

other species of *Python* may have attained in ancient times, but it is probably from some misconceived view of our present species that the marvellous traditions regarding almost immeasurable serpents have been derived. Who has not read of that enormous reptile which spread dismay even through a Roman army? It is thus related by Valerius Maximus, from one of the lost books of Livy, by whom it is said to have been recorded at greater length. "And since we are on the subject of uncommon phenomena, we may here mention the serpent so eloquently and accurately (1) recorded by Livy, who says, that near the river Bagrada in Africa, a snake was seen of so enormous a magnitude as to prevent the army of Attilius Regulus from the use of the river; and after snatching up several soldiers with its enormous mouth, and devouring them, and killing several more by striking and squeezing them by the spine of its tail, was at length destroyed by assailing it with all the force of military engines and showers of stones, after it had withstood the attack of their spears and darts; that it was regarded by the whole army as a more formidable enemy than even Carthage itself; and that the whole adjacent region, being tainted with the pestilential effluvia proceeding from its remains, and the waters with its blood, the Roman army was obliged to move its station: he also adds, that the skin of the monster, measuring 120 feet in length, was sent to Rome as a trophy." The learned Frienshemius, having had the advantage of living a thousand years or two after the historian of the Punic war, has given a still more circumstantial account of this bloody broil in his *Supplementa Livi*. He there informs us, that "it caused so much trouble to Regulus, that he found it necessary to contest the possession of the river with it, by employing the whole force of his army; during which a considerable number of soldiers were lost, while the serpent could neither be vanquished nor wounded, the strong armour of its scales easily repelling the force of all the weapons that were directed against it; upon which recourse was had to battering engines, with which the animal was attacked in the manner of a fortified tower, and was thus at length overpowered. Several discharges were made against it without success, till its back being broken by an immense stone" (we admire detailed accounts of ancient actions), "the formidable monster began to lose its powers, and was yet with difficulty destroyed, after having diffused such a horror among the army, that they confessed they would rather attack Carthage itself than such another monster." Probably such another was not then at hand, and we believe has never been seen since; but the anecdote itself holds out great encouragement to modern travellers. It is, we doubt not, to *Python bivittatus* that Bosman and other writers refer, when they mention the religious veneration with which some great African serpents are regarded by the natives. But we must conclude our imperfect notice of this genus by stating, that of the remaining species, *P. Schneideri* (Plate IV., fig. 3, and Plate V., fig. 5) is found in Malacca, Java, Sumatra, and Amboyna; *P. amethystinus*, in Saparua, a small island opposite Amboyna (a nearly identical kind being found in Timor, Samao, and New Ireland); and *P. Peronii* in New Holland.

Genus *ACROCHORDUS*. Head rounded, eyes extremely small, rather vertical, pupil orbicular, nostrils tubular, nearly terminal, opening forwards or upwards. Tail strongly prehensile, and, in common with the trunk, compressed. Anal hooks wanting. Whole body covered by small scales, and the abdomen furnished with a kind of keel beset with scales. Teeth as in the Boas proper.

The anomalous reptiles of our present genus may be said to combine the characters of the Boas and sea-serpents. Their dentition resembles that of the former, while the

position of the eyes and nostrils, the compact closure of the mouth, compressed form of the body, the existence of the abdominal crest, and absence of anal hooks, assimilate them to the latter. They are, however, easily distinguished by being destitute of poison-fangs. Want of attention to the latter character, and some confused and contradictory data furnished by foreign naturalists, have caused several errors in the arrangement of the species, which are very few in number. They inhabit the intertropical countries of Asia, are extremely aquatic in their propensities, and are externally distinguished by a somewhat sombre colouring,—brown and a yellowish hue being the prevailing tints. The Javanese species, *Acrochordus Javanicus*, is of a deep earthen-brown colour, irregularly marbled. Its form is thick, the head short and obtuse, the tail slender in proportion to the other parts. It attains a total length of eight feet, with the thickness of a man's arm, and was first described by Hornstedt, from a specimen taken in a large pepper-ground near Sangasan in Java.¹ *Ac. fasciatus* is also of a brown colour, but with paler bands upon the sides, the general form much more slender, and the dimensions considerably less.² It is more extended in its distribution than the preceding, being found in Pondicherry, New Guinea, Sumatra, Java, and Timor. It forms (it is said erroneously) the genus *Chersydrus* of Baron Cuvier,—the great French naturalist having been informed by M. Leschenhault that the snake in question was extremely poisonous, and dwelt in the beds of the rivers of Java. The accuracy of the former assertion has been since disproved. No other species are distinctly known.

Venomous
Serpents.

SECOND PRIMARY DIVISION.—VENOMOUS SERPENTS.

Family I.—Colubriform Venomous Serpents.

The poisonous species here assembled, although provided with envenomed fangs, so nearly resemble the Colubers in their general external forms as to be easily mistaken for them by an inexperienced eye. They also partake in some points of the features of the sea-serpents, but are distinguished by wanting the flattened tail; while from the concluding family of venomous serpents properly so called, they are kept apart by the bulkier proportions, thick triangular heads, vertical pupils, and carinated scales, which characterize the species last alluded to. At the same time it must be admitted, that those rigorous and distinct demarcations which so many lovers of nature desire to establish, but which so few can find, occur as seldom here as in other departments of zoology,—several species in each family showing a strong tendency of transition towards another.

The reptiles of our present family have a more slenderly elongated form than those of other poisonous groups. Their trunk is in general a good deal drawn out, sometimes cylindrical, or slightly compressed. Their tail, like that of all poisonous species, is rather short, conical, and rounded at the extremity. Their head, almost always of nearly equal dimensions with the neck, is small, short, and obtuse at the extremity. The eyes are rather small, sometimes vertical, the pupil always orbicular. The nostrils, always lateral and rather open, are pierced in a large plate on each side of the muzzle. The scales are not numerous, of medium size, and always smooth,—except in *Naja hæmachates*, in which they seem surmounted by a keel. The abdomen is constantly convex, and furnished with plates of greater or less extent, according to the species. But what particularly characterizes this family is, that all the genera of which it is composed have the crown of the head covered by nine plates,

¹ Act. Stockh. 1787; and Journ. de Physique, 1788.

² Shaw, Gen. Zool. iii. pl. 130.

Venomous
Serpents.

modelled after the type of those of *Coluber*. The poison apparatus is much less developed than among other venomous kinds; but the fangs, though short, are strong. The species inhabit the warmer countries of both the New and Old World, but do not occur in Europe. They form three generic groups, as after mentioned.

Genus ELAPS. Body slender and cylindrical, of nearly equal size throughout, and usually encompassed by fifteen rows of broad, smooth scales. Head elongated, and not strongly distinguishable from the trunk.

This genus was established by Schneider,¹ and now contains all those slender-bodied venomous kinds, which by their elongated forms remind us of *Tortrix* and *Calamaria*. They attain to no great size, seldom reaching three or four feet in length, and scarcely exceeding a finger's thickness in diameter. Their colours are often bright and beautiful, a combination of red and black being frequent among them. They prefer countries covered by an abundant vegetation, concealing themselves amid the herbs of the meadows, or the softer luxuriance of the forest; and with this circumstance we may connect the fact, that only a single species is found in Africa, all the others occurring in tropical America, New Holland, the Indian Archipelago, and Bengal,—the latter country, however, producing likewise only a solitary instance in *Elaps trimaculatus*. Their agility is by no means great, and they prey chiefly on other reptiles,—birds being probably too active, quadrupeds too large, and fish too aquatic for creatures of slowish movement, small size, and terrestrial habits. We cannot here detail the species, of which eleven are described by M. Schlegel, but must rest satisfied by referring, as examples, to a few figures, such as *E. Corallinus* (*Nova Acta*, x. pl. 4), *E. Surinamensis* (*Seba*, ii. pl. 86, fig. 2), *E. collaris* (*Erpétol. de Java*, pl. 45), *E. trimaculatus* (*Russel, Ind. Serp.* i. pl. 8).

Genus DENDRASPIIS. The only known species of this genus was first described by Professor Traill in Jameson's *Edinburgh Journal*. From his dislike to institute a new genus from a single species, he proposed for it the name of *Elaps Jamesoni*, as it most nearly approached that genus of poisonous reptiles. His specimen was sent to him from South America; but since that, M. Schlegel has received several specimens from Western Africa, of which it is certainly a native. From its narrow abdomen and habit of a tree snake, M. Schlegel suggested to Professor Traill the generic name of *Dendraspis*, which has been adopted, and the specific name remains.

Genus BUNGARUS. Form more robust than that of *Elaps*. Head broad, depressed, rounded terminally, and towards the sides; abdomen convex; tail robust; dorsal line furnished with a row of hexagonal scales larger than the rest; sub-caudal plates simple.

To this genus belong the *Bungarum pama* of Russel (*Ind. Serp.* i. pl. 3), *B. annularis*, Daudin, and the *Geedi Paragoodoo* of the former author, *B. semifasciatus* of Khul and Schlegel. Both species inhabit India, as well as Java and Ceylon. The natives of India, who are said generally to exaggerate the noxious character of their serpents, assert that the bite of the latter produces immediate death, although Dr Russel's experiments go to prove that it is seldom fatal to chickens in less than half an hour, or to dogs in a shorter period than an hour and a half. A *Geedi Paragoodoo* was made to bite a large dog on the thigh, near the groin, where it held fast for more than twenty seconds, but the fangs scarcely penetrated farther than the skin. The dog howled much when first wounded, but on being set at liberty walked about for a time without manifesting any peculiar symptoms. In ten minutes, however, he drew up the wounded leg, continuing to stand on the other three; in a quarter of an hour he crouched, and

Venomous
Serpents.

howled again, and the thigh became paralytic, though the poor creature was still able to raise himself: in twenty-five minutes both thighs were paralytic; and in the course of the second hour he became greatly disordered, grew apparently torpid, lay panting on one side, and died in about two hours, without convulsions. Another dog of smaller size expired in one hour and ten minutes, after being strongly convulsed for some minutes prior to its death.

Genus NAJA. General form robust; body not cylindrical, but thickening in the middle, and tapering towards either end; tail lengthened and conical; abdomen broad and convex; head well distinguished from the trunk; eyes large and lateral; neck capable of inflation.

This genus contains the famous hooded or spectacle-snakes called *cobras de capello* by the Portuguese, the majority having the power of raising the anterior ribs, so as to produce a peculiar disk-like inflation of the neck or upper portion of the body. The species are peculiar to the ancient world,—if New Holland, which produces two, and was unknown to the ancients, may be classed therein. M. Schlegel describes ten different kinds, many of which, however, are arranged in separate genera by other writers, but which that author regards as forming an uninterrupted series, closely connected with each other, and of which the foremost exhibit the announced generic characteristics in great strength and precision, while the others gradually depart from the type, and form a passage to the vipers.

The hooded snake, commonly so called (*Coluber naja* of the older writers, *Naja tripudians* of the recent systematists), is one of the most noted as well as noxious of the Indian reptiles. Its general length is from three to four feet, and the diameter of its body about an inch and a quarter. The inflated portion is marked above by a large conspicuous patch, closely resembling the figure of an old-fashioned pair of spectacles. The usual colour of the upper parts is pale ferruginous brown, the under being of a bluish-white occasionally tinged with yellow. The terminal portion tapers gradually, and ends in a rather slender sharp-pointed extremity. In India this dreaded species is more universally known than any other. It is frequently exhibited as a public show, and being carried about in a covered basket, is made to assume a kind of dancing motion (a modification, we presume, of some natural and instinctive movement) for the amusement of the public. Raising itself up on its lower extremity, and moving its head and body alternately from side to side, the insidious creature seems pleased by keeping time with the measured melody of "flutes and soft recorders." We presume that a love of music is natural to certain serpents; and that this fact was observed of old in Palestine, is probable from the expression of the inspired Psalmist, who compares the ungodly to the deaf adder, which "stoppeth her ears, and refuseth to hear the voice of the charmer." Chateaubriand relates that he was an eyewitness, on the banks of the Genesee, to the fact of a native appeasing the wrath of a rattle-snake (which he even caused to follow him) merely by the music of his flute. The dancing snakes of India are usually, though not universally, deprived of their poison-fangs. "When the music ceases," says Mr Forbes, "the snakes appear motionless; but if not immediately covered up in the basket, the spectators are liable to fatal accidents. Among my drawings is that of a *cobra de capello* which danced for an hour on the table while I painted it, during which I frequently handled it to observe the beauty of the spots, and especially the spectacles on the hood, not doubting but that its venomous fangs had been previously extracted. But the next morning my upper servant, who was a zealous Mussulman, came to me in great haste, and desired I would instantly retire and praise the Almighty for my good fortune. Not understanding his

¹ *Hist. Amphib.* ii. p. 289.

Venomous
Serpents.

meaning, I told him that I had already performed my devotions, and had not so many stated prayers as the followers of his prophet. Mohammed then informed me, that while purchasing some fruit in the bazaar he observed the man who had been with me the preceding evening entertaining the country people with his dancing snakes; they, according to their usual custom, sat on the ground around him, when, either from the music stopping too suddenly, or from some other cause irritating the vicious reptile which I had often handled, it darted at the throat of a young woman, and inflicted a wound of which she died in half an hour.¹ A similar fate had nearly befallen an artist employed by Professor Reinwardt to paint the portrait of a living Naja. It had in some way disengaged its bands, and seemed to have prepared itself to attack the unsuspecting painter the moment he entered his apartment. He there found it supported on its tail, its body raised, its neck dilated, its head advanced, and then giving utterance to some hissing sounds, it threw a quantity of saliva upon the very man who was about to hand it down to posterity, but who fortunately effected an instantaneous retreat before it came to closer quarters. We doubt not the painter loved the picturesque, although that was not the time to gaze with admiration on the fierce intruder.

Dr Russel informs us that he never knew the bite of a hooded snake prove mortal to a dog in much less than half an hour, although it kills chickens in less than half a minute. Now the rattle-snake has been known to kill a dog in less than two minutes. Yet the use of the lunar caustic, which in the hands of the Abbé Fontana proved so efficacious when applied as remedial to the bite of the viper, was found of little or no avail in India as a counteraction to the venom of the *cobra de capello*.² We shall conclude our notices of this species by observing that the Ceylonese jugglers, according to Dr Davy, use it without extracting the fangs, the only means which they employ to avoid its vengeance being courage and agility. It is in fact held in veneration by the natives of that island, who carefully avoid it, offer it no injury, and put it out of doors unhurt when it happens to enter their dwellings.³ The root of *Ophiorhiza mungos* is believed in India to be a specific against the bite of the *cobra de capello*.

Another noted species is the *Naja haje* (*Coluber haje*, Linn.), which plays the same part in the history and superstitions of the African tribes as the preceding does in those of the Asiatic nations. The ancient Egyptians named it *Ouro*, a term which signifies king, and which the Greeks adopted into their language in the word *Ouraios*. It is frequently represented in various Egyptian antiquities, whether as drawn in colours, sculptured on the covers of sarcophagi, or cast in bronze. One of the great creative spirits of the world, called Cneph, Cnophis, or Ammon, in the cosmogony of Egypt, was represented in their symbolical writings under the form of a serpent winding itself around a globe, or placed in the centre of a disk.

The jugglers of modern Egypt, especially of Cairo, use this Naja in their pretended sorceries. These people affect to be descendants of the ancient Psylli, and boast of inheriting from their ancestors the power of subduing and commanding the most poisonous reptiles. The principal feat which they execute consists in making the Naja counterfeit death, or they change it into a rod. This they seem to effect by pressing the neck of the creature between their fingers, so as to produce a kind of catalepsy, which renders it stiff and motionless. This is rather a singular fact when considered in connection with the scriptural narrative, where the rods of the magicians, when thrown down, are con-

verted into serpents.⁴ According to M. Geoffroy, the species is still sufficiently common in Egypt, occurring both in fields and ditches. "Les cultivateurs sont donc exposés à le rencontrer fréquemment; mais quoiqu'ils n'ignorent pas le danger de sa morsure, sa présence ne les empêche nullement de vaquer à leur travaux ordinaires; connaissant bien les habitudes du redoutable reptile, ils savent qu'ils n'auraient à craindre d'être attaqués par lui, que s'ils venaient à commettre l'imprudence de s'en approcher. En effet, tant qu'ils se tiennent à quelque distance, l'haje se contente de les suivre du regard, en élevant sa tête et en prenant l'attitude dans laquelle les fig. 4 et 5 le représentent."⁵ The African Naja attains to about the same size as the Asiatic, and greatly resembles it in general aspect; but its neck is less capable of inflation, and its muzzle more conical. It is usually of a yellowish-brown colour above, varied with numerous black and white spots; the under surface whitish, although some individuals exhibit broad black spots or bands on the abdomen. The Cape Naja is regarded by M. Schlegel merely as a climatic variety of that now mentioned.

The Australian species (*Naja porphyrica*) was first described by Dr Shaw.⁶ It belongs to the genus *Ophcephalus* of Baron Cuvier, and we place it here on the authority of M. Schlegel. According to M. Lesson it is greatly dreaded at Port Jackson, and several convicts are said to have died of its bite in a quarter of an hour. It is common in the sandy brushwood of the shores of Botany Bay. Its movements are full of force and vigour, its agility remarkable, and it defends itself when attacked with great hardihood.⁷ Another New Holland species is *Naja curta*, said to bear resemblance to a viper. It is probably the only colubiform venomous reptile which exhibits a somewhat vertically elongated pupil.

Family II.—Sea-Serpents.

Our present family is placed here on the supposition that all the species which it contains are poisonous. Several naturalists, proceeding on certain data given by Dr Russel, have maintained the contrary opinion; but long-continued researches on the part of M. Schlegel have led to the conclusion that there is really no exception to the rule. Great confusion prevails in the synonymy of the species, chiefly owing to the absence of good figures and accurate comparative descriptions,—even Dr Russel's plates, which are the most numerous, being insufficient to lead to a rigorous determination of the species. The specimens themselves are obtained with great difficulty, and are consequently rare in our collections.

We have not sufficiently precise information on which to settle the geographical boundaries of the marine family of serpents. That species occur in the Persian and Arabian gulfs is by no means improbable; but the fact is inferred rather from some passages in ancient writers than from modern observation; and we know that the authors of antiquity, at least in some instances, mistook certain eel-formed fishes for actual snakes. Schneider, indeed⁸ (whose competence as a *scholar* no naturalist would dare to doubt) has quoted several classical writers to demonstrate a remote knowledge of sea-serpents; but that knowledge seems too superficially and vaguely expressed to be altogether trusted or even understood. Ælian records that "the seas of India produce hydras with flattened tails."⁹

Modern naturalists are believed to be in error who assert their occurrence in the Atlantic Ocean, no proper proof having been yet adduced of any of these species inhabiting it.

Venomous
Serpents.

M. Schlegel characterizes the statement as an "assertion que je puis contredire avec certitude." Believing that there are more things in heaven and earth than are "dreamt of in our philosophy," and desiring to bear in mind the sentiment of the inspired apostle, that "if any man think that he knoweth any thing, he knoweth nothing yet as he ought to know," we shall content ourselves by stating that sea-serpents have not yet been observed in the Atlantic Ocean. M. Schlegel's researches have led him to believe that they are confined "aux mers intertropicales, ou voisines des tropiques, comprises entre le 90^{me} et les 230^{me} degrés de longit. or. du méridien de Ferro."¹ We shall here state the chief of the actual localities. Several species were received by Dr Russel from among the numerous islands called Sunderabunds, which form the delta of the Ganges. The same author likewise obtained many from different points along the coast of Coromandel. Sir Stamford Raffles mentions three species which frequent the coasts of Sumatra.² The Dutch voyagers have observed only a single species on the coast of Java, but they have met with several among the Moluccas, near Timor, Banda, and the shores of New Guinea. Dr Strauss transmitted two species from the Celebes. M. Von Siebold observed them to abound in the China Sea, and met with many in the course of his passage from Java to Japan, from the region of the equator as far north as the 27th degree. Escholtz has incidentally observed,³ that the fishermen of the Philippine Islands capture *Acrochordus fasciatus* in the Bay of Manilla, and that this reptile cannot move upon the land. Now it so happens that the *Acrochordi* correctly so called never inhabit the sea; and it may therefore be inferred that the observer last named had in view, not an *Acrochordus*, but a sea-snake or *Hydrophis*. It is long since Dampier told us of those which he saw along the western shores of New Holland;⁴ as did afterwards Sir Joseph Banks along the eastern coast, from the 20th to the 10th degree of north latitude. Forster, as Schneider has recorded, found *Hyd. pelamys* abundant near Otaheite.

The habits of these reptiles are indicated here and there by different writers. Dr Russel describes their aquatic movements as active and elegant, but they have scarcely any locomotive power on land, and speedily die when either brought ashore or placed in fresh water. He found in the abdomen of a female *Hydrophis* nine perfectly formed young, each of which was enclosed in an egg or envelope, from which (the matured condition) it may be inferred that they are viviparous. It would also seem that their manners are milder than those of the generality of poisonous species. Dr Russel, at least, assures us in regard to *Hyd. gracilis*, that no provocation would induce it to bite any object presented to it. Neither could M. Lesson succeed in his disinterested attempts to make *Hyd. pelamys* wound any poultry, though he kindly put them together alive into a copper bathing tub.⁵ The observations received from M. Von Siebold by M. Schlegel confirm the belief of other naturalists, that these reptiles, though assuredly dangerous from their poisonous qualities, are not of a highly ferocious nature. The former traveller fell in with vast numbers while sailing from Batavia to Japan, all of the small species, elsewhere so frequent and widely spread, known to naturalists by the specific name of *pelamys*. Their movements were by no means rapid, although they glided through the water with grace and activity, raising their heads from time to time above the waves, for the purpose probably of respiration. Their motion is produced and directed by an action of the tail, accompanied by a lateral and undulating movement

of the other parts of the body. They were easily enough entrapped in wooden buckets, and glided through the sailors' hands without attempting to bite them,—the said sailors having probably been previously informed that they were eels. "Le Professeur Reinwardt," says Schlegel, "confirme ce que M. von Siebold rapporte relativement au caractère doux et tranquille de ces animaux."⁶ We cannot, however, help thinking that this alleged sweetness of temper and tranquillity are in some measure inconsistent with the cases of the native woman and Lascar already reported in our introductory observations. The comparatively slow movements also do not accord with what we are elsewhere informed by M. Lesson. "Le 27 Juillet," says that naturalist, "par une journée brûlante, nous fûmes pris de calme sur les côtes de la Nouvelle Guinée. De nombreux serpents marins passèrent le long de la corvette, et un embarcation que le capitaine fit mettre à la mer nous permit de les chasser. Nous atteignîmes après de longues poursuites une Pelamide, dont l'agilité était extrême, et les mouvements de natation des plus rapides."⁷

We owe some interesting observations on the manners of these marine serpents to M. Peron,⁸ although it may be doubted whether that voyager did not occasionally take his notes from too great a distance, especially in reference to size and colour. No other credible author has ever described any of these species as attaining to so great a length as twelve feet; the usual dimensions, we may here observe, varying from two and a half to five feet. However, M. Peron describes those he saw as gliding lightly in great numbers on the surface of the sea, and waging destructive war against a shoal of small herrings, which fled precipitately towards deeper water. The haunts of these snakes are by no means confined to the shallow shores, or even the vicinity of continents or islands, for they are often met with many hundred miles from land. On opening their stomach, our navigator found it filled with small fish, and various marine crustacea; but the reptiles themselves became the frequent prey of sharks, in the interior of which their half-digested remains were often found. It naturally became a subject of surprise, that creatures so light and active should so often fall victims to an enemy of such weight and sluggishness; but after more lengthened observation, a peculiarity in the habits of the former was thought sufficient to account for their capture. These serpents were often seen as if asleep, and floating on the waves, and so profound was their repose, that a large vessel, "with all its bravery on," might pass close by without their being disturbed by its surging prow, its huge furrow, or the loud voices of the garrulous sailors (Frenchmen, of course). M. Peron supposes that it is in this state of lethargy that the lazy sharks swallow them at their leisure. As to the cause of the torpor itself, he naturally enough suggests that it may arise, as among the terrestrial races, from repletion, and the indolence indulged in by all serpents during the digestive process. "Ces reptiles," he adds, "nagent et plongent avec une égale facilité: souvent à l'instant même où nous croyons pouvoir les saisir avec nos filets, ils disparaissent à nos yeux; et, s'enfonçant à de grandes profondeurs sous les flots, ils restaient une demi-heure et plus sans remonter à leur surface, ou ne paraissaient qu'à de très-grandes distances du point où nous les avions vus plonger."⁹

The general ground-colour of the majority of these reptiles is yellowish, varying towards green, blue, or white, and often relieved by blackish rings, or broad lozenge-shaped spots, disposed transversely along the dorsal re-

Venomous
Serpents.

gion. The colours seem less subject to variation than among the other Ophidians, and there is no external difference between the sexes. All the species are included by M. Schlegel in the following genus.

Genus HYDROPHIS. Head small, uniform with the trunk. Nostrils vertical, of an orbicular form, and capable of being closed by a valve. Eye small, pupil orbicular. Fangs but slightly developed, and always followed by several other teeth, solid though slender. Body tapering towards both extremities. Scales lozenge-shaped or hexagonal, not imbricated, covered by a thin epidermis, and surmounted by a tubercle, of which there are two on the median range of the abdomen. The abdominal scales scarcely larger than the others. Tail broad, flattened laterally, and performing the functions of an oar or rudder. Lungs often prolonged into a reservoir of air as far as the commencement of the caudal region.

Of this genus there are seven species, the particular characters of which we cannot here detail, although their general attributes may be made out from the preceding observations. (See Plate V., fig. 4.)

The most common kind is *Hyd. pelamys* of Oken¹ (*Anquid platyura*, Linn.), of a comparatively thickish form, the head much elongated, the median line of the abdomen indicated by a suture formed by two rows of scales. It is of a blackish brown above, beneath yellow; the tail, and sometimes the entire body, varied by these colours. It is the most extensively distributed of the genus, being found wherever any sea-snakes occur. It seems to be the black backed hydus of Shaw (*Hydrus bicolor*, Schneid.); and in India rejoices in the euphonious name of *Nalla Wahlagillee Pam.*² Of general occurrence in the Asiatic seas, it is also common round the coasts of Otaheite, where it is relished as an article of food, and known under the title of *Etoonatoree*.

Family III.—Most Poisonous Serpents.

The species of this family are the most venomous of all, and may, for the most part, be recognised by something especially repulsive and forbidding in their aspect. Their form is rather thick and heavy, their tail short, their head extremely broad, depressed, and somewhat heart-shaped; rarely protected by plates, but usually covered by scales resembling those of the dorsal region; the eyes are small, deeply seated in the sides of the head, and shaded by projecting superciliary plates, the pupil vertical; the upper lip is inflated, and falls over the lengthened fangs; the body is usually beset by scales of a lanceolated form, surmounted by a ridge, except in one or two species of *Trigonocephalus*, in which they are smooth.

Their habits and modes of life likewise present some disparities when compared with those of the preceding groups. Being of a lethargic nature and slow of movement, they seldom wander about in search of prey, but keep themselves coiled up till it approaches closely, and then springing upon it by a sudden straightening of the body, they inflict a fatal wound, which needs no repetition. There seems reason to believe that this mode of attack is peculiar to the present family, the other poisonous kinds pursuing their prey, and *holding on* when they have seized it, while the poisonous serpents properly so called are satisfied by sinking their envenomed fangs into the flesh of their victim. Their gape is very wide, their fangs long and sharp, their poison abundant and in a state of high concentration, and the wound is inflicted suddenly,

with great force. The result is left to nature, and is in consequence both sure and speedy.

Venomous
Serpents.

We have said that the poison-fangs are more developed than among the other Ophidians. They alone occupy the maxillaries, being never followed by any small solid teeth, though these occur along the palate and at the extremity of the lower jaw. The nostrils are in some spacious, in others narrow, and vary also in their position. They are followed in certain species by a deep pit or hollow, scooped in the sides of the muzzle, and connected with a broad cavity in the upper maxillaries. This character (of which, however, we know not the function) seems analogous in some measure to the *larmiers* of ruminating quadrupeds, and has been employed for the distribution of these serpents into several groups. Such as are distinguished by this nasal pit inhabit the forests of tropical countries, and consist of two genera, *Trigonocephalus* and *Crotalus*, of which the former (native both to Asia and America) is chiefly found in moist and sombre woods, or places covered by an abundant vegetation; while the latter (peculiar to the western world) prefers a somewhat drier and more barren soil. Such as possess no nasal excavation are comprized in the genus *Viperus*. They affect a more open, sandy soil, and occur exclusively in the ancient continents and New Holland. We shall briefly survey these different groups, in the order now named.

Genus TRIGONOCEPHALUS. Head, as in other members of the family, heart-shaped or triangular, extremely broad behind, and consequently very distinguishable from the neck. Tail terminated by a conical corneous plate.

The poison apparatus of these reptiles is developed in the highest degree; and as the species sometimes attain a length of five or six feet, they may be regarded as among the most redoubtable of venomous serpents. They all frequent wooded or shady situations, or moist meadows in the immediate vicinity of forest-land. The abdomen is always broad, rather convex, and furnished with plates, which vary, according to the species, from 140 to about 270. The tail is always short, conical, and usually somewhat slender. The sub-caudal plates vary from forty to seventy; and of these some are simple, others divided into two. The body is often marked by large irregular or lozenge-shaped spots upon a brownish or yellowish ground. Some, however, are reddish, others of a greenish hue, and there is frequently a line of deeper hue behind the eye. The species are rare in collections. None occur in Europe or Africa. America and the intertropical countries of Asia produce a large majority. The genus is divisible into two sections, according as the head is covered with scales or with plates.

One of the most noted species of the first section is *Trig. lanceolatus*, a native of the West Indies.³ The general colour is greenish yellow, paler beneath, and variously marked with specks, spots, and bands of brown. A broad brown line, bordered with white, proceeds from the eye towards the mouth. We have a good account of the habits and history of this reptile from Colonel Moreau de Jonnés.⁴ He tells us of one killed by an officer which measured above seven feet and a half in length; and still greater (but perhaps less accurate) measurements are given by Dutertre⁵ and Labat.⁶ In the bodies of such females as were examined, he found some fifty or sixty young ones, which, when the period of their birth arrives, issue forth completely formed, and much inclined to bite. In the adult state they prey chiefly on rats, which, though not indigenous to these islands, are now in all probability as 10,000 to one compared with the native quadrupeds. The snakes in question

have also multiplied prodigiously in St Lucia and Martinique, where from sixty to eighty may be killed during the cutting of a single field of sugar-cane. According to M. Moreau de Jonnès, they people the marshes, the cultivated grounds, the forests, the banks of rivers, and even the summits of the mountains. The observer just named encountered one on the very edge of the crater of that naked mountain which overhangs the town of St Pierre, in Martinique, at an elevation of more than 5000 feet; and he feared it the more from the excessive lassitude under which he himself at that time laboured. His alarm was not without cause, for only a few days before, a fisherman at the foot of the mountain had been attacked by a similar reptile, which issued from its concealment among the basalts of the shore, and no efforts could save his life. These dreaded serpents are sometimes found in holes made by rats or land-crabs. They also enter hen-roosts and poultry-yards, and sometimes creep into dwelling-houses, chiefly, however, the huts of the negroes. But the sugar-plantations are their favourite places of resort. "Je n'ai jamais trouvé," says our author, "de serpent stationnaire, qu'il ne fût dans une position offensive. L'action par laquelle le reptile prend cette position, s'exprimer aux Antilles par le verbe *lover*. Elle consiste à contourner en spirale toute la longueur de son corps, qui forme quatre cercles égaux en diamètre, superposés les uns au dessus des autres, et sous le dernier duquel la queue est placée comme point central d'appui, de resort et de pivot. La tête, qui termine le cercle supérieur, est retirée en arrière. Quand l'animal s'élance sur une proie, il fait effort sur la queue, et déroule subitement les quatre cercles qui semblent se débâter." This species preys on birds as well as quadrupeds, and the former manifest their hatred by vain and clamorous cries whenever they behold their "arch destroyer." It avoids the brilliant equatorial light, and usually dwells in shaded places, seeking what it may devour chiefly towards sunset, or during cloudy weather.¹ The distribution of this species is rather remarkable. It does not extend throughout the whole of the Antilles, nor is it found even in the majority of those islands. "By a chance equally singular, fortunate, and inexplicable, it is confined to the islands of Martinique, St Lucia, and Beconia alone; and there is no proof, as has been pretended, that it is common in the American continent. Nevertheless, a tradition exists among the Indigenes, that it was introduced into Martinique by the Arronages, a horde which inhabited near the mouth of the Orinoco, and which, impelled by sentiments of hatred and vengeance against the Caribs of that island, made them this fatal present, and let loose in their forests this serpent, which was brought over in calabashes. But according to another popular opinion in the same country, the Trigonocephalus is aboriginal of Martinique, and cannot live elsewhere, not even in Guadalupe.

Some, however, think differently, and explain the phenomenon by the existence of the dog-headed serpent, which is believed to be a Boa, and which, common in Dominica and St Vincent, has delivered these islands from the Trigonocephalus."²

Venomous
Serpents.

Of the second section of this genus, comprising such as have the head covered by plates instead of scales, we may here name *Trig. rhodostoma*, which is of a thicker and more vigorous form than the other species. The body tapers towards either end, the tail is short and acuminate, the abdomen broad, and the back prolonged into a well-marked keel. The colour is reddish brown, paler on the back, the sides adorned by broad, deep, triangular spots, the abdomen white. The summit of the head is black, surrounded by a broad streak of pale red, which descends the sides of the neck to combine with the beautiful rose-colour which tinges the lateral parts of the head, and from which it is separated by a black band proceeding from behind the eye. The iris is of a golden yellow. "L'expression sauvage de sa physiognomie," says M. Schlegel, "est, pour ainsi dire, adoucie par la nature et la conformation des plaques écailleuses qui semblent à celles de la plupart des couleuvres, ont la surface unie et luisante."³ This species inhabits the western parts of Java, where it conceals itself in tangled vegetation, and makes its way at times into fields and gardens. It preys chiefly on frogs, and is itself attacked by a species of civet cat which occurs in Java. It is greatly dreaded by the natives on account of its deadly poison; and during M. Khul's residence at Buitenzorg, two labourers bitten by it died in five minutes. Although a viviparous reptile, the foetus is enclosed in a coriaceous envelope, as large as a pigeon's egg. The species is figured by Russel.⁴

The only other example of the genus we need here notice is *Trig. cenchrus*, which inhabits the southern provinces of the United States. Its occipital plates are of small dimensions, and are sometimes even wanting. The ground colour is grayish brown, marked by broad transverse bands of a more coppery hue. The abdomen is yellowish, marked by dark irregular spots. The point of the tail is usually black, and all the parts are minutely speckled by that colour. It is a sluggish, slow-moving reptile, very poisonous, but not given to bite, except in self-defence, when it maintains its position courageously. It has been described by different authors under a great variety of names, and by some under more than one at a time.⁵ It is the *Mohassin* snake of the Anglo-Americans, thus called on account of the resemblance of its colour to the piece of dress so named by the native tribes. It is figured by M. Daudin.⁶

Genus CROTALUS. This dreaded genus contains the rattle-snakes, and is distinguished from the preceding by a more robust form, a thicker head, and a tail either armed

¹ *Monographie*, p. 37.

² Griffith's *Animal Kingdom*, ix. 350.

³ It is both the brown and the black viper of Catesby's *Carolina*, pl. 44 and 45; it is once figured, and at least twice described, by Dr Shaw, as *Col. Cacademon* and *Tsiphone*, *Gen. Zool.* iii. pp. 377 and 406; it is the *Pelas Niger* of Merrem, *Tentamen*, p. 149; and had been previously described by Linnæus as a Boa (*B. Contortrix*, xii. ed. p. 373). M. Schlegel, indeed, supposes that it is also the *Culuber Constrictor* of the great Swedish naturalist. The Boa just named is believed to be identical with the hog-nosed snake of Catesby (*Car.* ii. pl. 56), and may be identical with the preceding nominal species, none of which seem to exceed the size of our common viper; but *Col. Constrictor* of America is usually described as of different habits and much larger dimensions. It is the black snake of Catesby (*Car.* ii. pl. 48). "This," observes that author, "is a large and very long snake, some being six feet in length. They are all over of a shining black, never changing their colour, and are very nimble and beneficial in killing rats, which they pursue with wonderful agility to the roofs and all parts of houses and barns, where rats are able to run, for which service they are preserved by most of the inhabitants. They are bold and furious, leaping at and biting those that attack them, though no harm ensues, *their bite not being venomous*. It is said in Carolina that they will attack and swallow rattle-snakes. It is certain most or all snakes will devour one another, not only of their own, but of other kinds, which I have often seen; one, after a long struggle, swallowing another but little less than itself. They are the most numerous of all snakes." "Many ridiculous frights," says Mr Pennant, "have happened from this innocent reptile. As every one in America is full of the dread of the rattle-snake, they are apt to fly at the sight of any of the serpent kind. This pursues, soon overtakes, and twisting round the legs of the fugitive, soon brings him to the ground; but he happily receives no hurt, but what may result from the fright. All the mischief this species does is to the housewives, for it will skim their milk-pans of the cream, and rob their hen-roosts of all the eggs." (*Arctic Zoology*, Appendix, p. 92.)

⁴ *Indian Serpents*, ii. pl. 21.

Venomous
Serpents.

by a peculiar organ called the rattle, or prolonged into a sharpened point. There are four species, all peculiar to America. These are often confounded, even by systematic writers; and it is by no means easy to apply the general attributes assigned by travellers to the proper species, which no doubt differ from each other.

It seems ascertained, however, that the bite of all these reptiles is extremely dangerous, the slightest prick of their envenomed fangs, in any part of the body well supplied with blood-vessels, being sufficient to kill almost any animal. Laurenti says, that a person bitten by a *Crotalus* experiences a swelling of the entire body, the tongue becomes prodigiously inflamed, an unextinguishable thirst takes place, the edges of the wound become gangrened, and the unfortunate victim dies in frightful agony in five or six minutes. Different experiments made in Carolina by Captain Hall, are related in the Philosophical Transactions. A rattle-snake, four feet long, was fastened to a stake, and being made to bite three dogs, the first died in less than a quarter of a minute; the second, in convulsions, in about two hours; the third in about three hours. Four days after this, another dog was bitten by the same snake, and died in half a minute; and then a second received the murderous fangs, and died in four minutes. A common black snake, about three feet long, and very vigorous, was next procured. The reptiles bit each other,—the black snake dying in eight minutes, the rattle-snake not seeming in any way affected by its wound. Proceeding upon the supposition that “none but itself could be its parallel,” it was then made to inflict a bite on its own body, and this suicidal deceit was followed by the hoped-for consequence,—it died in less than twelve minutes. The story is probably well known to all, though not credited by so many, of a disagreeable kind of an heirloom which once existed in an American family. A man had been bitten through his boots by a rattle-snake, and died. The boots afterwards descended into the successive possession of two other persons, and killed them both,—an envenomed fang having remained sticking in the leather. As usual, we have contradictory accounts of the effects of corresponding causes. We know that an Englishman who was unfortunately bitten by a rattle-snake at Rouen, in 1827, expired in eight hours; yet in the April of that same year, at a meeting of the Academy of Sciences in Paris, Professor Bosc declared that he had seen more than thirty persons who had been bitten by rattle-snakes, not one of whom had died. According to Kalm, even the largest animals, such as horses and oxen, die almost instantly. Dogs longer resist this fatal action. Most animals exhibit an instinctive horror on nearing one of these death-dealing creatures. “I have often,” says M. Bosc, “amused myself by trying to force my horse and dog to approach one of these animals. But they would sooner have allowed themselves to be knocked down upon the spot than have come near them.” Yet Mr Audubon informs us that the mocking-bird of America, so strong and overpowering is the instinct of parental love, does not hesitate to attack the rattle-snake when it approaches too near its nest,—that it will strike it on the head, pick out its eyes, and eventually put it to death.

The so-called *rattle* of these reptiles consists of a series of hollow, vertically flattened, scaly pieces, of which the posterior portion of one fits into the anterior portion of that which follows. They are thus mechanically and somewhat loosely connected together, without being actually joined, so that when shaken they make a rattling or rustling noise, resembling that produced by crumpled parchment. When young there is at first but a single horny portion at the end of the tail, and attached to the last caudal verte-

bra. Another is formed on the renewal of the skin, pushing its predecessor onwards, so that the first joint, which is closed at the end, continues to be the terminal one. M. Bosc is of opinion that an additional joint is formed every year, and that if the parts in question were not so often broken off accidentally, we might thus determine the age of each individual. They are, however, extremely fragile; and M. Palisot de Beauvois informs us, that he frequently found these rattles lying detached, in the course of his travels in the United States.¹ Their amount sometimes exceeds thirty, but usually ranges from one to thirteen. Some say that the noise may be heard at the distance of a hundred feet, while Bosc and others allege that it is scarcely audible beyond some twelve or fifteen paces. We shall now briefly notice the different species, the names of which, as already hinted, have been frequently transposed by naturalists.

Crotalus horridus inhabits South America, and is known to the Portuguese by the name of *Carcavela*. Its muzzle is covered by three or four pairs of plates. The scales, which are lozenge-shaped, and surmounted by a cutting keel, are disposed in twenty-nine ranges. Abdominal plates 145, sub-caudal twenty-five. The colour of the upper parts is yellowish brown, relieved upon the back by a range of broad, lozenge-shaped spots. This species measures from four to six feet in length, and, dwelling in a sultry clime, continues in a state of activity throughout the year. Some singular peculiarities in its manners are narrated by naturalists. For example, M. Palisot de Beauvois states, that during one of his journeys he observed a rattle-snake lying on the path, and approached it as quietly as possible. When he was about to strike it, it sprung its rattle, opened its mouth very widely, and received into its throat five young ones, each as thick as a goose's quill. After ten minutes' time, believing itself to be out of danger, it opened its mouth, and allowed the exit of the young, which, however, re-entered on a fresh alarm. This curious fact has been testified (if not confirmed) by another French gentleman, M. Guillemart.

Crotalus durissus (Plate IV., figs. 6 and 10) is a more northern species than the preceding, and to it we may refer the numerous observations which have been made by travellers and tourists on the rattle-snakes of North America. It seems to inhabit from the southern side of the Great Lakes as far as Mexico and California, extending westwards to the foot of the Rocky Mountains, but not occurring to the north of the river St Lawrence. It has only one or two pair of plates upon the muzzle, and the keel upon the scales is less developed; the eyes are smaller, the tints deeper, the spots frequently assume the form of bands, and the tail is black. Abdominal plates 170, sub-caudal twenty-two. As this species dwells in districts subjected during winter to the influence of rigorous cold, it creeps in autumn into covered places, or, hiding itself beneath masses of sphagnum, falls into a state of lethargic repose. An individual killed by M. Bosc, and which did not measure more than four feet in length, was found to have a hare in its interior. Its usual food consists of rats, squirrels, and other small Rodentia. This serpent, commonly called the striped rattle-snake, is said to traverse rivers, and even lakes, by inflating its body like a bladder. “The largest rattle-snake,” says Catesby, alluding to one or other of these species, “which I ever saw, was about eight feet in length, and weighing between eight and nine pounds. This monster was sliding into the house of Colonel Blake of Carolina, and had certainly taken up his abode there undisturbed, had not the domestic animals alarmed the family with their repeated outcries; the hogs, dogs, and poultry united in their hatred to him, showing the greatest consternation, by erecting their

Venomous
Serpents.

bristles and feathers, and expressing their wrath and indignation, surrounded him, but carefully kept their distance, while he, regardless of their threats, glided slowly along." "It is not uncommon," he adds, "to have them come into houses; a very extraordinary instance of which occurred to myself in the same gentleman's house, in the month of February 1723. The servant, in making the bed in a ground room (but few minutes after I left it), on turning down the sheets, discovered a rattle-snake coiled between the sheets in the middle of the bed." According to M. Audubon, the skin of this species is used in making shoes.¹ Mr Say informs us that it inhabits bare and sterile regions, and is often found in the subterranean dwelling of a marmot, *Arctomys Ludovicianus*.² M. Becker of Darmstadt placed two rabbits in a cage with this species, one of them being white, the other reddish brown. The fierce reptile, which was lying in a spiral form in the centre, sounded its rattle, and raised and extended its head from time to time, but made no attempt to seize its prey, although repeatedly provoked by its keeper so to do. A black rabbit was then introduced, which it bit instantaneously, and the victim was dead in eight minutes.³

Crotalus miliaris is a small species of North America, recognisable by its head clothed with nine well-developed plates. The eyes are large, the general colour a reddish brown, with three ranges of deeper spots. There are twenty-three rows of scales, and the lower plates are, abdominal 131, sub-caudal twenty-six. This snake was observed by Catesby in Carolina, and is described by Mr Say (under the title of *Crot. tergeninus*) as an inhabitant of those lonely sterile plains which stretch between the Mississippi and the Rocky Mountains. It is regarded as more dangerous than the preceding; its small size and peculiar colour prevent its attracting notice, and its rattle is too feeble to be heard at any distance. People are thus apt to tread or even to sit down upon it unawares, and the consequences are as easily imagined as described. It lives on frogs and insects, is by no means timid, but is easily killed by the slightest blow. It was figured long ago both by Seba⁴ and Catesby.⁵

Lastly, *Crotalus mutus* differs from the other species in having the tail terminated by a hardened point instead of rattle. Its head is clothed with scales. The back is keeled, and the scales are surmounted by a tubercular ridge. Abdominal plates 227, sub-caudal forty-nine. This great serpent inhabits Cayenne, Essequibo, Surinam, and other parts of South America. It sometimes measures above ten feet in length, and may be regarded as the most gigantic of all poisonous reptiles. In its mode of life it somewhat resembles *Trigonocephalus* (and is in fact described as a species of that genus by Baron Cuvier⁶). But it is essentially a rattle-snake, though destitute of the particular part from which these species derive their general name. It seems the same as that described under the title of *Curucucu* by Marcgrav.⁷ Its poison has been experimented on by Dr Hering.⁸

Genus VIPERA. Nasal pit wanting. Head usually covered by ridged lanceolated scales. General form thickish, tapering towards each extremity. Tail short and conical.

The species of this genus, greatly restricted since the time of Linnæus, still exhibit a considerable diversity of character when compared among each other. They inhabit either open sandy plains, or desert heaths, where the vegetation is not umbrageous. Hence their abundance in

Africa, and their comparative scarcity in other countries. None occurs in America, a few are found in the drier districts of Asia, three inhabit Europe, and one (of a somewhat anomalous nature) is native to New Holland.

Venomous
Serpents.

The common viper of Great Britain, and of most parts of the Continent (*Vipera berus*, Daudin—*Coluber berus*, Linn.),⁹ is the most poisonous of European reptiles. It rarely exceeds two feet in length. The upper portion of the head is protected by a few plate-like scales, somewhat larger than the others. The usual colour is pale ashy brown above, with a space between the eyes, and a patch on each side of the occiput, deep brown or black. A zigzag band of black (composed in some of confluent spots) extends along the back from the nape to the tail; and there is also a parallel row of small black spots on each side. The abdomen and sub-caudal region are steel-blue, sometimes marbled by a yellowish tint, sometimes uniform, or nearly black. The abdominal plates are about a hundred and forty-five,—the sub-caudal about thirty-five. This species is widely spread over the central and northern parts of Europe, but some uncertainty prevails regarding the so-called common viper of Italy and other southern regions. M. Gisl describes the viper of the environs of Munich as having an upturned snout,¹⁰ which is a character of the aspic; and although Metaxa enumerates *Vipera berus* and its varieties as occurring in the Roman territories,¹¹ others are of opinion that all its alleged localities are doubtful beyond the Alps.¹² It seems, however, to be found in the temperate parts of Siberia, in Russia, Hungary, all Germany, parts of France, Holland, Denmark, Sweden, and, we believe, Norway. Though common in Great Britain, and many of the western isles of Scotland, it is not indigenous in Ireland. Its vertical as well as horizontal range is considerable, for although it affects the low wide heaths of Groningen, Overijssel, and Friesland, it also occurs on the summit of the Inselberg in Thuringia, at an elevation of nearly three thousand feet above the level of the sea. The viper preys chiefly on mice and insects. A specimen, on the tail of which we inadvertently tramped while crossing a moor in Glenmuick, and which our friend Dr Greville struck down with his umbrella, was found on dissection to have a large field-mouse in its abdomen. Schlegel describes ten species.

The bite of this reptile is seldom fatal to animals of moderate size. We have several times seen sporting dogs bitten by vipers on the Scotch moors; and although the cheek might swell, and a heaviness of spirits, and disinclination to distant ranging, usually ensued for a few hours, no perceptible effect could be traced on the following day. A sparrow, however, or even a pigeon, dies in a few minutes after being bitten. Sheep usually escape without any serious consequences. Fontana ascertained, that the hundredth part of a grain of poison was sufficient to kill a sparrow, and that a pigeon required six times that amount. From these data he made a calculation, that it would take nearly three grains to kill a man, and as a viper does not carry above two grains of poison in its vesicles, and does not entirely exhaust that quantity, even after many bites, it was concluded that a human being might receive the bite of five or six vipers without dying in consequence. Now this may be all accurately reasoned in its way, but as physiology is by no means a science of calculation, we would not advise any one to try the experiment. Several facts have been recently adduced to prove, that the bite of this reptile is frequently dangerous, and occasionally fatal. Dr Paulet, in his obser-

¹ *Edinburgh New Phil. Journ.* iii. 21.² *Expedition to the Rocky Mountains*, p. 234 and 236.³ *Isis*, 1828, p. 1132.⁴ *Vip. berus* of Cuvier, and of some other French naturalists, seems to be identical with the aspic, *vipera aspis*,—a species common in France and Switzerland.⁵ *Isis* for 1829, p. 1071.⁶ *Thesaurus*, ii. pl. 95.⁷ *Carolina*, pl. 42.⁸ *Trig. rhombifer*, *Règne Animal*, ii. 90.⁹ *Hist. Schlegel's
Arrangement.

variations on the viper of Fontainebleau, states, that an infant of seven years and a half, which was bitten beneath the internal malleolus of the right foot, died at the end of seventeen hours,—while another infant of only two years, which was bitten in the cheek, took two days to die. Dr Hervez de Chegoni mentions the case of a woman, aged sixty-five years, in good health, and of a sound constitution, who having been bitten in the thigh only once by a single viper, expired under the most deplorable symptoms in thirty-seven hours.

The aspic, *Vipera aspis*, is a species nearly allied to the preceding, of which it is by some regarded as a variety, and of which it seems to assume the place in the south-western countries of Europe, extending as far as the island of Sicily.¹ Its form is more slender, its head larger, its top covered by irregularly-formed scales, and the muzzle is slightly turned up. The aspic is the species which served the experiments of Redi, Charas, and Fontana. It inhabits the dry and rocky countries of Italy, has been observed in Switzerland, and is common in France from the 49th degree of north latitude, spreading into Savoy, the Pyrenees, Spain, and the Mediterranean shores. It is the viper of Fontainebleau, and is also found in the forest of Montmorency; but in Burgundy, and the more northern parts of France, it is replaced by our common viper.

New Holland produces a rare and remarkable species, which some class as generically distinct, under the title of *Acanthophis*. It is of a thickened form, with a slender hard-pointed tail, the upper part of the head protected

by nine plates. The eye is surrounded by plates, of which the superciliary are elevated, and inclined towards the top of the head. It is the *Vipera acanthophis* of M. Schlegel,—*Acanthophis cerastinus*, Lacépède.² (See Plate V., fig. 8.)

A still more remarkable and anomalous species is the famous *Vipera cerastes* of Africa, figured and described by Bruce the traveller,³ and also in the great French work on Egypt.⁴ Its head is very broad, and heart-shaped; its muzzle broad, obtuse, and rounded; its nostrils rather narrow, vertical and terminal; and its scales surmounted by a tubercular ridge. One of the superciliary scales on each side is converted into a projecting horn-like process, curved forwards; and the ancient name *cerastes* is no doubt derived from this peculiar character,—the Greek word *κέρας* signifying horn.

Cornua prætendens immania fronte cerastes,
Dum torquet spinam sibilat ecce vagus.

It seldom much exceeds a foot in length, and inhabits the sandy deserts of the north of Africa. Its description by Bruce has been so often quoted that we shall rest satisfied by the reference already given to the writings of that impugned author.

Very similar to the *Vipera cerastes* of Egypt is the *Vipera nasicornis* of the western coast of Africa, which has two of the scales on its snout elevated above the general surface. It was discovered during Captain Tuckey's voyage.

ORDER IV.—BATRACHIA. BATRACHIAN REPTILES.

We now proceed to the fourth order of the class Reptilia, the BATRACHIA, a name derived from *Batrachos*, a frog, and expressive of a general resemblance which very distinctly marks the majority, although in truth many resemble lizards, and a few have more the appearance of eels or serpents. This tribe is one of the most singular in nature; for, besides the naked body and remarkable sanguineous circulation, they possess another peculiarity, which is regarded by many naturalists as sufficient to constitute them a distinct class rather than an order, viz., the change of form which they undergo in their progress from the young to the adult state.

In this concluding order are ranked all those reptiles which have neither the carapace of the Chelonia nor the scales of the other orders.¹ Their bodies therefore are naked; their head is without any distinct neck or division; their toes are always distinct, and without claws; they have no external organs of reproduction, and usually undergo metamorphoses. This change of form constitutes the Batrachia the principal step in the transition between terrestrial and aquatic vertebrata or fishes, and is one of the most singular phenomena presented by animal life. Bred

¹ A curious link, we perceive, has recently been discovered in South America, between the Batrachia and the Chelonia, which is nothing less than a frog furnished with a carapace and plastron.

Batrachia. after the manner of fishes, from spawn-like ova, they possess for a time the essential characters of the finny race; and yet, on the lapse of a few brief weeks, their pisciform appearance vanishes, and leaving the water, they crawl or leap about upon the earth, or climbing the stems of forest trees, they dwell among the umbrageous branches. In some the transition state, if we may say so, continues permanent, the gills existing simultaneously with feeble lungs, and a tail being combined with short external members. Of the structure of these curious animals more will be said hereafter.

The *ovum* or *egg* of these reptiles is a round mass of transparent nutritive jelly, in the centre of which appears a small black globule. By degrees this shapeless globule exhibits the appearance of a head and tail, and in this state it emerges from its prison, and moves about briskly in the water. It is provided with a long fleshy tail, and a small horny beak, and has no other visible member, except two feathery tufts on the sides of the neck, which float loosely, and without protection, in the surrounding fluid. These, however, are mere temporary organs; for they serve the purpose of respiration only until the proper gills are formed, and then shrink or disappear.¹ The true gills or branchiæ are contained within the body, three or four in number on each side, constructed on a plan similar to those of fishes; the water entering by the mouth, and escaping in some species by two openings, and in others by one only. Retaining their aquatic constitution, the *tadpoles* (as in this intermediate state they are often called) rapidly increase in size and activity for some weeks. In the mean time the legs, of which no trace was at first apparent, have commenced their growth. The hind ones are the first to make their appearance externally, although the anterior pair are as soon developed, and may be seen at an early period folded beneath their transparent covering. The animal at this period wears a very ambiguous appearance, partaking both of the form of the frog and lizard, and swimming as well by the inflection of the tail as by the irregular impulse of the feet.² At this time the beak falls off, and the true jaws, which originally were hid under the skin, appear. The eye, too, which had been seen only through a transparent spot in the tadpole's skin, appears complete and prominent. This interval is also employed in acquiring the faculty of respiring atmospheric air. The animal every now and then rises to the surface and takes a mouthful of air, which is received into the newly formed lungs, and then discharged. When the necessary internal changes are at length completed, the tail, which has now become a useless member, diminishes and disappears. The gills, too, have by this time shrunk, their function being superseded by the lungs, and the animal emerging from the water, begins a new mode of existence as a perfect reptile.

During its aquatic state the tadpole lives principally on vegetable food, but in its perfect form much more upon various insects; and there is a remarkable and corresponding change in its digestive organs, which assume the character of those of a carnivorous creature. Most of the *Batrachia*, we may also remark, are oviparous, whilst not a few of them are ovo-viviparous. It should, moreover,

be observed, that most of the species of this group, during *Batrachia*, their aquatic condition, possess the extraordinary power of suffering the privation of a part, or the whole, of one or more of their members without vital injury, and of afterwards renewing them as if no loss had been endured; a property of which we have already made mention in our summary account of lizards, and to which we may again briefly return in our notice of the aquatic salamander.

We shall now take a nearer view of the vascular and respiratory systems of these animals. The *circulation*, in the tadpole state, is in every respect analogous to that of fishes: the blood is transmitted from a simple bilocular or two-lobed heart to the branchial arches, and, after *aeration* by the water, returns, and is circulated through the system. The transition from this condition to that which the vascular organs present in the perfect reptile state is very striking. Originally three or four branchial trunks pass off from each side of the heart, and terminate in the minute network of the gills; from this network the returning vessels take their origin, one from each of the gills, the first of which goes to the head, and the other two conjoining, convey the blood to the rest of the system, as in fishes. But in addition to these vessels, there are some small undeveloped ones, which effect a communication between the vessels which go to the gills and those which return from them; as also another which, given off from the heart, unites with the aorta, to be distributed to the as yet rudimentary lungs. After the metamorphosis is begun, the branches which connect the arteries of the gills with the returning veins are greatly enlarged, so that a part of the blood flows continuously through them without proceeding to the gills at all, and the proper branchial vessels relatively diminish; and the last-named trunk, which was the smallest of all, becomes the largest, and an increased proportion of blood is sent to the lungs. By a continuance of these changes, the branchial vessels are finally obliterated, and the communicating branches, at first only secondary and irregular, now constitute part of the continuous and permanent system of circulation.

The *respiration* of the *Batrachia*, after they have arrived at their permanent mode of existence, is not less singular than their circulation; and this chiefly in two particulars,—as it regards the lungs, and the function of the skin. If we take a frog, for example,³ and watch its respiration, we cannot readily discover that it breathes at all; for it never opens its mouth to receive air, and there is no motion of the sides to indicate that it respires; and yet, on any sudden alarm, we see the animal blowing itself up, as if by some internal power, though its mouth all the while continues closed. We may perceive, however, that its throat is in frequent motion, as if the frog were economizing its mouthful of air, and transferring it backwards and forwards between its mouth and lungs; and if we direct our attention to the nostrils, we may observe in them a twisting motion at each movement of the jaws; for it is through the nostrils that the frog receives all the air which it breathes. The jaws are never open but for the purpose of eating; and the sides of the mouth form a sort of bellows, of which the nostrils

¹ This change or conversion from external to internal gills is not very satisfactorily described by physiological observers. “Dès le moment où les Batraciens sortent de l'œuf, ces branchies sont apparentes au dehors, elles représentent des espèces de franges ou de panaches colorés situés sur les parties latérales du cou, et attachés sur les bords des fentes qui correspondent à la gorge; elles persistent sous cette forme, dans tous les Batraciens qui conservent leur queue, tant que leurs poumons ne sont pas assez développés pour servir uniquement à la respiration. Dans les Grenouilles et autres genres voisins sans queue, le premier état ne dure que pendant un temps très court. Bientôt l'animal prend une autre forme, celle d'un têtard à ventre énorme confondu avec la tête et avec une longue queue. Les branchies sont alors cachées, et contenues dans une cavité; l'eau arrive dans la bouche par les orifices des narines,” &c. (*Erpétologie Générale*, i. 182.)

² It appears that the great Lord Bacon had not practised his inductive philosophy so far as young frogs are concerned, for in his *Sylva Sylvarum* he makes mention of their being sometimes observed with tails, in such years as have been more than usually pestilential or unhealthy; and he then draws the conclusion that the appearance of such tailed reptiles, “argueth a great disposition to putrefaction in the soil and aire.”

³ See Roget's *Bridge-water Treatise*, ii. 330.

Batrachia. are the inlets; and by their alternate contraction and relaxation, the air is swallowed and forced into the windpipe, so as to inflate the lungs. The tongue also contributes its share in carrying on this function. This organ is remarkable in its connection, being fixed very differently in these from what it is in most other animals. Its root is not situated deep down the throat, but is attached superficially at the fore-part of the lower jaw; it is remarkably long, and instead of inclining forward, is turned backwards, extending down the throat, and so acts as a valve, affecting the entrance and exit of air from the lungs. If the mouth of the frog be forcibly kept open, it is suffocated, because it is deprived of the power of swallowing the required air; and if the nostrils be closed, it in like manner can no longer breathe. Hence the frog and allied genera may be said rather to swallow air than to inhale it. Respiration, again, is not carried on, as in most animals, by the chest, but by the compression of the muscles of the abdomen; and if these are in any way injured or destroyed, the breathing ceases, and the individual speedily dies. Nor is the function of respiration in the *Batrachia* confined to the lungs; for the blood which circulates through the capillaries of the skin is likewise aerated by communication with the atmosphere. This kind of respiration, closely connected with the extraordinary perspiration for which these animals are celebrated, is of such importance to them, that if impeded by covering the skin with oil or other unctuous substance, death will take place almost as soon as if the lungs were removed; and, on the other hand, the animal may be supported by it alone, for a considerable time, if the temperature be not too high,—a physiological fact which, we apprehend, goes a great way to account for the extraordinary power possessed by many of these creatures (to which we shall afterwards allude), of enduring, without detriment, a long protracted burial, enclosed in wood or stone.

The reproductive act in these reptiles, somewhat intermediate between what occurs in terrestrial animals and fishes, is so remarkable that it must not be passed by. We shall borrow our illustration from what occurs in the frog, the genus by much the best known in the order. The embraces of the male occur only once a year, and in spring. As soon as the sun's influence is felt in their wintry resorts, the black spongy knob at the base of the thumb of the male augments in size, and his abdomen swells. On finding his mate, he mounts on her back, extends his arms round her chest, and so locks the fingers of his hands into each other, that, from the peculiar structure, they cannot be separated. The two animals are thus inseparably joined, and so live and swim together for fifteen or twenty days, or even for a month. If, under these circumstances, the thumbs be cut off, the junction is at an end; but if the animal be decapitated, the grasping apparatus still performs its mechanical office. During the period of this long embrace, the spawn, as in fish, escapes in long floating cords or chaplets, of a gelatinous fluid, crowded with the ova, which is bedewed with the milt of the male. When the spawning is completed, the male frog is able to dismount, the fingers speedily regaining their flexibility, and the thumbs their ordinary form. The reproductive power is very great, the ova amounting to from 600 to upwards of 1000. Swammerdam once reckoned 1100 from a single individual, and Montbeillard 1300.

It is remarked that these animals live to a great age, if fortunate enough to escape the attacks of their enemies; an instance will be given in the sequel, of an individual whose history was traced for forty years. Their foes, however, are very numerous. A number of quadrupeds,

birds, reptiles, and fishes, live habitually at their expense. *Batrachia*. Serpents, pikes, vultures, and storks, destroy an immense number of them. Without the intervention of the last-named birds, Egypt, in particular, would swarm with frogs. In several countries, certain species are sought after by man; and they are considered by competent judges as an agreeable and wholesome food. The *Batrachia* have no weapons either of offence or defence. Taken as an order, they are certainly as harmless to man as any tribe of animals; and, as has been well remarked, though the forms of many of the species offend our notions of beauty, and their love-songs have gained them the character of "horrible musicians," there is certainly nothing to justify the aversion and disgust with which they are so usually regarded.

The *Batrachia* generally feed upon the larvæ of aquatic insects, on worms, small mollusca, flies, &c., and always choose a prey which is living and in motion. Dead and motionless animals are rejected by them. To obtain their prey, they often remain fixed in one situation, with wonderful patience, watching till they believe it is within their reach, and then darting at it with great rapidity, they at the same time protrude their lengthened tongue, bedewed all over with a viscid fluid. If we watch a frog when an insect has approached sufficiently near it, we are surprised to observe the insect suddenly disappear without our being able to perceive what has become of it. This arises from the frog having darted its tongue upon its victim with such extreme quickness, and again withdrawn it with the adhering insect, that it is scarcely possible for the eye to follow it in motion. Thus from the nature of their food, so far from being prejudicial, they are very useful in gardens, by extensively destroying those small slugs, &c. which are so detrimental to plants of every kind.

FAMILY RANIDÆ.¹ FROGS IN GENERAL.

All the members of the frog family (corresponding to the great genus *RANA* of Linnæus), have in their perfect state four extremities and no tail. Their head is flat, their muzzle rounded, their mouth very large. In the greater number the tongue is not attached to the deeper part of the throat, but to the edge of the lower jaw, and thence proceeds backwards, and down the throat. Their front feet have only four toes, and their hind five, sometimes exhibiting the rudiments of a sixth.

We cannot better bespeak a favourable consideration for this despised group than in the words of an enthusiastic naturalist. "We shall have considerable difficulty," says the eloquent Lacépède, "in assigning to frogs the place which they should occupy in the minds of our readers, such as it really is in nature; but it is not less true, that if toads had never existed, if we had not before our eye this horrid object of comparison, which caricatures by its resemblance, as it defiles by its approach, the frog would appear to us as agreeable from its conformation, as distinguished by its qualities, and interesting from the phenomena it exhibits at the different periods of its existence. We would behold it as a useful animal, from which we have nothing to fear, whose instinct is harmless, which unites an elegant form with supple and slender limbs, and is adorned with pleasing colours, rendered more vivid from the kind of natural varnish with which the animal is constitutionally provided. And who can regard with pain a being whose form is light, whose movements are nimble, whose attitudes are graceful? Let us not deprive ourselves of an additional source of pleasure;

¹ Although the patronymic termination in *idæ* is not classically correct in cases where the primitive has a feminine termination, we nevertheless follow in this matter the suggestion of Mr Kirby, and the example of Mr Macleay, who regards it as preferable to any other yet devised, as well on account of uniformity, as *euphonia gratia*. See *Hortæ Entomologica*, p. 23.

Batrachia.
Ranidæ.

and, in our peregrinations through the smiling fields, let us not regret to see the banks of rivulets adorned by the colours of these harmless creatures, and animated by their light and lively gambols. Let us contemplate their little manœuvres; observe them in the midst of stilly lakes, the solitude of which they diminish without troubling the repose; see them exhibit, under sheets of water, the most agreeable tints, cleave the bosom of the tranquil stream, and vary its silvery surface with many a circling furrow."

In summer these Ranidæ are usually found in humid places, in grassy meadows, and on the banks of streamlets, into which, when approached, they usually leap and dive. They swim admirably, by means of their webbed hind feet. Frequently at the close of warm rains they spread themselves through the country, and are so numerous as to be crowded and pressed against each other in places where they had never been observed before. To this appearance is owing the popular belief of *rains of frogs*, which undoubtedly is usually a mistake; but raised by a hurricane, and thereby transported to a great distance, such an occurrence is yet, we believe, quite within the range of possibility. As soon as the summer is over, and the weather begins to get cold, these reptiles lose their natural activity, and give over feeding. When the cold becomes more considerable, they protect themselves from its rigour by sinking into the mud in deep water, in the holes of fountains, and even in the earth. The quantities which sometimes thus collect in one place are so considerable, that they have been known to cover the soil to a foot in depth, and thousands may be taken in a few minutes. Hearne informs us, in his voyage to the Icy Sea of North America, that he many times found under the moss frozen frogs, whose legs might be broken without their exhibiting any sign of life, but which resumed their energy with returning warmth.

GENUS RANA, Laurenti, Cuv. *Frogs proper.* This first genus of the Ranidæ has the body slender, the hind feet very long, and more or less webbed; their skin is smooth; their upper jaw is furnished all round with a row of minute sharp teeth, and there is an interrupted transverse range in the middle of the palate. The males have on each side, beneath the ears, a fine membranaceous bag, which they expand with air when they croak. They leap and swim admirably. (See Plate VI., fig. 1.)

The skeleton of the frogs does not present any trace of ribs; and the breast-bone, very large, with collar-bones attached, is merely cartilaginous. The cranium is almost prism shaped, flattened above, and very broad behind, and is less round than in the toads. The vertebrae are ten in number. The muscles have a considerable resemblance in arrangement to those of man, and are very strong, very irritable, and very sensible to the action of galvanism. The muzzle in frogs is somewhat more acute than that of toads; and the nostrils are visible at the summit. Their orbits are large, and are directed upwards; the eye is large and brilliant, and surrounded by a bright golden circle. The lids are three in number, and all horizontal; the upper one is a mere projection of the skin; the lower is more mobile; and the third, which is quite transparent, moves from below upwards, and is most of all in action. We have already dwelt so fully on the habits of the whole group, that little requires to be added in this place. It is, however, a curious circumstance, that these animals, like many other inhabitants of the water, can become habituated to the very high temperatures of thermal springs. Thus Reaumur mentions that he had known one found alive in water about 111° Fahrenheit; and Spallanzani mentions an example of this kind where, in the baths of Pisa, they were exposed to a temperature of 138°.

The power of voice in frogs, commonly called croaking, is exercised by the different species in very different degrees; a remark which is also applicable to the genus *Bufo* in their more limited range of expression. It is more par-

ticularly during the time of rain, and in hot days, in the evening and morning, that they indulge in their harmonious concert. The noise which they make becomes sometimes insupportable. It is principally the males which croak; their voice being stronger in consequence of the two sacs which they possess on the sides of the neck, and which swell out under the effort. As for the female, she has only a slight swelling in her throat, and produces but a feeble note. During the feudal regime in France, when all the castles were surrounded by water, it is said that it was the business of the serfs to attack the frogs, and prevent them from disturbing the morning repose of the lordly inmates.

It is rather remarkable that these creatures should be so much esteemed as delicious food in some countries, and so much despised and even abhorred in others. The ancients appear not to have discovered the nutritive virtues of frogs, nor their value in the science of gastronomy. In the sixteenth century, however, they were served up at the best tables on the continent. In Britain this kind of aliment is held in detestation, whilst in France and other European countries a very great consumption takes place. They are captured in various ways; either with lines, or small nets, or by means of a rake. Sometimes they are pursued at night, and with torches, the light of which attracts them. In Vienna, where they are rather favourites, they are fattened in *froggeries* constructed for the express purpose. Though one species of frog is called par excellence the *edible*, yet several others partake of this distinction. In Germany all parts of these animals are eaten, the skin and offals excepted. In France it is the larder quarters alone which are used. They are dressed like fish, with white sauce, and in wine, or they are fried or even spitted. A foreign species of great size, to be afterwards mentioned (*R. grunniens*), which abounds in the West Indies, is often domesticated there for the use of the table. The flesh is white and delicate; it is fricasseed like fowl; and two frogs make a good dish. Nor is it *frogs proper* alone which are used in this way. The abhorred toads are habitually eaten by the negroes, both in Africa and America; and there seems to be little doubt that even in Paris the thighs of these animals are constantly sold for those of frogs.

We now proceed to a rapid sketch of the most remarkable species.

***R. esculenta*, Linn.** The *edible frog*, *green frog*, or *common frog of France*. The colours of the green frog vary so much, that different individuals might almost be taken for a diversity of species. It is often of a beautiful green colour, spotted with black, with three yellow stripes on the back, and the belly yellowish. This description generally holds good in the environs of Paris. Those in the rivers and ditches of Lombardy have the back of a uniform green colour. Another variety, which has been observed in Holland, has the lips black, round black spots on its sides, and the belly entirely white; in Provence it has a reddish belly; and in the neighbourhood of Beauvois, sombre green, with transverse brownish spots upon the limbs, is found to be the prevailing hue. It varies in size from two to three inches, measured from the snout to the end of the body. It abounds in all dead and still waters, and is pre-eminent for its croaking powers. It is very common in France, Italy, and Germany; but is rare in Britain. It supplies, in the former countries, a very wholesome and agreeable food. It deposits its ova in small bundles, in the pools. This species seldom removes far from the margin of some quiet streamlet, into which it plunges on the least noise. It swims in the same manner as man, with its head above the surface. It may be often seen amusing itself among aquatic plants, darting after insects on the wing, mounting upon the umbrageous leaves, or squatted on the bank, with its snout projecting as if to court the rays of the sun, in which it delights, even during the most scorching days. It is indeed

Batrachia.
Ranidæ.

Batrachia.
Ranidæ. most agile in this kind of weather, and leaps with the greatest liveliness. It feeds solely upon living objects, and will swallow no animal whose motions do not prove it to be in life. Its voracity is so extreme, that it may be captured with almost anything which is made to move, and will dart at a hook when baited with a rose or poppy leaf. With the warmth of autumn the gaiety of the green frog ceases; and as winter becomes severe, it entirely disappears, plunging deep into the mud to secure an asylum from the cold. Here they often crowd together, as if for the purpose of keeping each other warm.

R. temporaria, Linn.; *R. fusca terrestris*, Roes. The common frog of Britain. The red frog of the French. This species, the most common in Britain, and also abundant throughout Europe, has the same elegant and slender form as the preceding, and differs from it merely in its colour, which is often of a russet hue, like that of decayed leaves, varied in front with black spots between its brilliant eyes and upper lip. These spots sometimes assume the form of whiskers passing down the neck. It is of the same size as the preceding, and is met with from early spring-time till towards the close of autumn, leaping in woods and meadows, sheltering itself beneath hedges, and penetrating into cottage-gardens, where it ought to be protected, as waging deadly war with destructive snails and insects. It proves quite as good eating as the green frog, and in France is often placed upon the table. It is by no means so great a croaker as the preceding species; and those accustomed to the latter think it does not croak at all. It is most generally found upon land in the summer season; and while the green frog rarely abandons the immediate neighbourhood of still or gently flowing waters, this species is often found in brushwood, remote from the banks of streams. At the approach of winter it retires into fountains and ponds of pure water, usually, it is alleged, avoiding miry places. Nor does it bury itself in mud like its congener; for numbers of these frogs may be taken during the winter by making holes in the ice. It lays its ova at a later season than the green frog, and the development of its tadpole is slower. Like the preceding, it presents many varieties of colour, which it would be tedious here to name.

Under the appellation of *R. cultripes*, Cuv., may be noted a frog which occurs in the south of France, bespeckled with black spots, its feet extensively webbed, and especially remarkable for having a vestige of a sixth toe, armed with a horny and cutting nail. The spotted frog (*R. punctata*, Daudin) occurs in the neighbourhood of Paris, though not very common. It rarely exceeds an inch in length. Its gray colour is relieved by a number of green spots over the body, and a black spot behind the eye, and it is said to change its colour when alarmed. Its toes are only partially webbed. The folded frog (*R. plicata*, Daudin) is found in the most southern parts of France. It is of the same diminutive size as the last, of a brown colour above, and gray beneath; the fingers quite free, the toes semi-palmated. It is particularly distinguished by having two folds of the skin on each flank; and there are four large brown spots on the chest and arms. Our knowledge of the brawling frog (*R. clamitans*, Bosc) is due to the indefatigable Bosc, who discovered it in the marshes near Charlestown, United States. It is about two inches long, of a dull ash colour, spotted with black, the upper lip green. Its vivacity is extreme, and it is by far the most lively of all known frogs, so that it is extremely difficult to catch it if it once makes its escape. It does not remove far from water, and when hunted, shoots into the stream with a sharp cry. Its continual croak is almost insupportable.

The bull-frog of the Americans, *R. pipiens*, Linn., is one of the largest species of the genus, being three or four inches broad, and six or eight long; and when measured with extended legs, its entire length is about eighteen inch-

es. The hind limbs are long, stout, and deeply palmated. It is of a dull green colour, varied with black, and relieved by a coppery yellow circle which surrounds the tympanum, and marks the situation of the ear. It abounds in Carolina and Virginia, remaining at the entrance of its hole, near some fountain, into which it precipitates itself on the least alarm. Catesby affirms that it utters sounds very much resembling the bellowing of a bull, and with greater force when at the bottom of the water. During the summer evenings, and in dry weather, it makes indeed a most astounding noise. It is exceedingly partial to young ducks and goslings, which it swallows whole, and will proceed to a considerable distance from its home in search of prey. As the voracity of this species is proportioned to its bulk, it is rare to find more than a single pair in each marsh. This frog is very difficult to catch; it is only during the night, and when it removes a little from its haunt, that it is possible to procure an individual. When on level ground it makes leaps of from six to eight feet in length. Baron Cuvier justly remarks, that several species go under the general name of bull-frog in America.

The grunting frog, *R. grunniens*, Daudin, is of the same large dimensions as the preceding, and inhabits the Floridas and the West Indies, where it has been accurately observed by M. Moreau de Jonnés. It is vulgarly designated a toad, because it frequents shady and humid places, and not the vicinity of waters, as the other frogs. In its habits it is nocturnal, and its strength is so great that at a single spring it can clear a wall five feet high. It is very torpid during the dry season, but resumes its vivacity when the rains set in. It is this frog which is often domesticated in the West Indies for the use of the table, and becomes tolerably familiar; the flesh is white and delicate, and two frogs form a very good dish. The argus frog of Shaw, *R. ocellata*, Linn., is often mistaken for the preceding. It inhabits Pennsylvania and Carolina, and was first figured by Seba. It is one of the largest of the genus, equalling if not exceeding the bull-frog in size, and being stronger; it is of a pale reddish-brown colour, striped with chestnut; the feet are unwebbed, and each joint is furnished with a kind of tubercle. The laughing frog, *R. ridibunda*, Gmel., according to Pallas, is common about the Ural and the Caspian Sea. It is of great size, weighing half a pound. It always keeps in the water, and in the evening utters its croakings in a way that resembles a horselaugh. The paradoxical frog, *R. paradoxica*, Linn., the jackie of the French, is remarkable for the great size of its tadpole state in proportion to the adult animal. The loss of its enormous tail, and of the envelopes of its body, induces a great diminution in bulk; its length in the tadpole state being seven or eight inches, while that of the body when transformed is only three. Thus many of the first observers were led to the conclusion that it was the frog which was metamorphosed into the tadpole, or, as they declared, into a fish. This species is green, spotted with brown, and is especially recognised by irregular stripes of a brown colour running along the limbs. The male has a gular sac, and the hind foot is provided with a supplemental toe. It inhabits Guiana. Our readers will bear in mind that in the preceding list we have not attempted more than to give a specimen of the distinctive characters and habits of some of the best-established species. Many more have been described and catalogued in systematic works.

GENUS CERATOPHRIS, Boié, Cuvier. This genus is distinguished by the great size of the head, by the skin being rough, and engrained in whole or in part, and by a membranous or horn-like prominence on each eye-lid. (See Plate VI., fig. 2.) In certain species the tympanum is hid beneath the skin. The species are found in South America and Asia. The horned frog (*C. varius*, Boié, *Rana cornuta*, Seba) is certainly one of the most singular of

Batrachia. the Batrachia, having an aspect exceedingly deformed. This arises not so much from the general shape of the animal, as from the extraordinary structure of the upper eyelids, which are so formed as to resemble a pair of strange sharp-pointed horns, while the width of the mouth exceeds that of its congeners, and equals half the length of its body. Seba, in fact, describes it as having two sharp horns on its head, within which its eyes are situated; and Schneider more accurately, as a pair of acuminate callous processes, of a conical shape, placed upon the eyelids. The colour is grayish yellow, striped with brown. The body is rough, with pointed spines. The head is very large and thick, and the tongue proportionably so. Baron Cuvier assigns five species to this genus, from the works of Seba, Daudin, Spix, and Prince Maximilian. In Mr Gray's catalogue an additional one is furnished by Mr Wagler, the habitat of which is Asia.

GENUS DACTYLETHRA, Cuv. The south of Africa, according to Cuvier, produces a group of Batrachians which resemble the frogs in their teeth, their smooth skin, their pointed toes, those of the hind feet being deeply webbed, and the inner three having their extremity enveloped in a conical nail, which is black; their head is small, and their mouth not very large. The tongue, attached deep in the throat, is fleshy and large; their tympanum not apparent. These numerous distinctive characters have induced the baron to constitute a new genus under the above name, from *δακτυλίζεα*, a *thimble*. The *smooth toad*, *crapaud lisse* of Daudin (*Pipa bufonia* of Merrem), belongs to it.

GENUS HYLÆ, Laurenti; *Calamita*, Schn. The *tree-frogs* of the English,—*Rainettes* of French authors. The Hylæ were first separated from the frogs and toads by Laurenti, and his arrangement is now universally followed. They differ from the other genera in having all the extremities of their toes enlarged, and rounded into a kind of disk or cushion, usually covered with a viscid humour, which enables them to attach themselves firmly to foreign bodies, and to climb trees. (See Plate VI, fig. 3.) Trees, in fact, constitute their abode during the whole of summer, and there they hunt for food. They, however, produce their ova in water, and shelter themselves in the mud during winter. They have a gular pouch, and are good croakers.

The disks with which the toes of the tree-frogs are provided are simply fleshy, and in the form of lentils. Examined with the microscope, they appear like porous sieves, from which a glutinous fluid slowly exudes; they are usually somewhat concave, and are sometimes furnished with a distinct fold. By means of this apparatus the species can attach themselves to smooth surfaces; they can leap from branch to branch, and can traverse twigs when agitated by the wind. They may be regarded as among the most nimble of their kind. They are, however, more tranquil than many, and watch most patiently for prey. In the day time, and especially when the sun's heat is great, they are said to shelter themselves among the thick foliage, putting themselves in motion on the approach of evening, and then sporting with delight. The croaking of these animals is similar to that of the proper frogs, but stronger, though not quite so sharp. It is most frequently heard in wet weather; but on a beautiful summer evening the traveller is sometimes surprised by a vast group of these hoarse musicians, assembled on the tops of the highest trees. They feed on the insect tribes. Late in the season they retire to the water, where they pass the winter in a kind of lethargy, and remain there till the spawning season has elapsed. Some Indian species deposit their eggs on the under side of leaves hanging over water; and General Hardwicke has observed them place their ova on a leaf which stood over a pail of water, so that the young dropt into the fluid beneath. There is not a single species of the tree-frog in the British isles; they occur, however, frequently in the more favoured climes of Europe,

and superabound in warmer regions. The number of ascertained species is not inferior to that of the frogs proper. They are among the most interesting of the race, and many of them are very beautiful.

H. Arborea, Cuv.; *R. Arborea*, Lin. *Common tree-frog*. In beauty of colouring, as well as in elegance of form, and general agility of movement, the tree-frog exceeds every other European species. It is found in France, Germany, and Italy; but more towards the south than north. It avoids dry situations and mountainous forests, and delights in humid woods, in hedges bordering on marshes, and in parks and gardens ornamented with water. Its principal sojourn during the summer months is the upper parts of trees, searching for insects, which it catches with extreme alacrity, stealing softly upon them, as a cat towards a mouse, and seizing them with a sudden spring of frequently more than a yard in height. It often suspends itself by its feet, or by a single foot, or even by its abdomen and drawn-up toes from a twig, or the under portion of a leaf, thus continuing beneath the shade. It is among the smallest of European frogs. Its colour is green above, more or less bright; its belly whitish, and covered with numerous small tubercles; a dark violet-coloured streak runs along the flanks; and the limbs are reddish. The body is smooth above, and rather short and plump; the hind legs are very long and slender. The fore feet have four toes, the hind five, and all of them terminate in dilated flattish tips. The surface of the abdomen is very remarkable, being so granular, adhesive, and elastic, that it enables the animal to adhere almost to anything, even, it is said, to polished glass, at whatever inclination, or in whatever position it is placed. The spawn is deposited towards the end of April, and the perfect animal appears in August, when it ascends the neighbouring trees, and assort with its parents. Being very noisy on the approach of rain, this species is considered as an excellent barometer; and in the German *Ephemerides* there is an account of one which was kept in a state of domestication for seven years, and gave the greatest satisfaction from being peculiarly weather-wise.

The *Zebra hyla*, *H. calamita*, Gray, *Calamita maxima*, Schn., appears to be one of the largest of these slender-bodied frogs, a specimen described by Seba having attained the length of five inches. It is a native of Carolina and Virginia. It is of a rufous-brown colour, striped with chestnut bands; all its feet are webbed, and the toes orbicular. The *Merian hyla*, *H. Meriana*, Gray, *Rana Meriana*, Shaw, first depicted and described by Maria Merian, in her *Surinam*, merits a distinct notice. It is about three times the size of the common hyla; and on each side of the neck has a remarkable protuberance, resembling an obtusely conical inflated pouch; its hind feet are distinctly webbed. It is of a brownish-green colour above, and is variegated with patches of yellow. It is found sometimes on trees, and sometimes in water. Mad. Merian states that they have external ears, and that the balls on their toes facilitate their progress over the soft marshes which they frequent. The *H. tubatrix*, Laurenti, is an American species, and is said by Seba to croak in a melodious manner during very hot weather after the setting of the sun, while in the cold and rainy season it is silent, concealing itself at the bottom of the waters.

H. lateralis, Catesby, has been observed in Carolina, and also, it is said, in Surinam. It is usually found attached underneath the leaves of trees, concealing itself, and lying secure from birds and serpents, its most dangerous foes. They are sometimes found in vast heaps, the bushes and woods being completely covered with them; and their croaking may be heard at the distance of whole leagues. They make prodigious leaps, and hence in the United States are called the crickets of the savannahs, their cry

Batrachia.
Ranidæ.

Batrachia.
Ranidæ

also resembling the noise made by that insect. *H. tinctoria*, Cuv. *R. tinctoria*, Lin. or *Dyung Hyla*, has a singular property assigned it, apparently on good authority. It is said that by its means the American Indians partially change the plumage of their parrots from green to red. With this object in view, they pluck out the green feathers when the bird is young, and rub the wounded skin with the blood of the hyla, after which the feathers spring up of a fine red or yellow colour. It inhabits Surinam and Guiana, requesting the woods nearly the whole year, concealing itself in clefts of trees, and under the bark in cold nights, and resorting to water only for the purpose of reproduction. Cuvier has enumerated, as among the largest and most beautiful, the *H. bicolor* of Daudin and Spix; it is of a celestial blue colour above, and of a rosy tint below. He has catalogued several additional species; and Mr Gray's list is very extensive, including some species from New Holland.

GENUS BUFO. The generic characters of this group, which includes the toads, are, a body thick, short, clumsy, and generally covered with warts and pimples, with a glandular pad behind the ears, from all of which distils a milky fetid humour; there are usually no teeth; the hind feet are frequently short, and hence the species rather crawl than leap; and they are generally found at a considerable distance from water. By Linnæus they were incorporated in the same genus with the frogs, and so close is their resemblance, that that arrangement is still sometimes followed. Toads have in all times and places been regarded as disgusting animals, and sometimes even as objects of horror. They are usually believed to be venomous, and are consequently subjected to proscription and extermination. It will be found, however, on examination, as has been observed by a noted naturalist, that these animals are comparatively harmless, that the study of their organization involves much interest, and that their history presents a crowd of facts equally curious and important. A slight sketch of the structure and habits of these despised animals having already appeared in our general remarks on the order, we shall here allude only to a few distinguishing traits.

The European toads are stated to have only eight vertebrae, and some as few as seven. Though generally described as wanting teeth, yet some species have them on the gums, large and curved. The tongue is not forked, as in most of the frogs; nor do they possess the gular pouches, which give to the frogs their peculiarly resounding voices. The glandular cushion-like body behind the ears, sometimes stated as the most distinct mark of the genus, is considered by Schneider as nothing else than the parotid gland, well known in man as the seat of that disease called the mumps,—with what degree of accuracy we are not prepared to say. The toads, in general, are heavy sluggish animals in comparison with frogs, and sometimes even crawl with difficulty.

The cuticular excretion usually regarded as so offensive is possessed by frogs as well as toads; but is much more abundant in the latter. It is alleged that the toad can at will increase the secretion of this viscous humour, and cause it to distil like dew from all its pores. The most important use, as previously suggested, is probably connected with respiration; the one usually assigned is, that it defends the animal from the heat of the sun and the dryness of the air. This abundant perspiration must, of course, maintain the species at a low temperature; and Adanson states the fact to be so well known, that the negroes in traversing the burning sands of Senegal are in the habit of applying a live creature of this kind to the forehead for the purpose of cooling it. These reptiles have the power of emitting another secretion, which is regarded as a weapon of defence and offence. It is discharged from the lower gut, is shot forth in a small stream, and often occasions apprehensions from its supposed venomous nature. When toads are surprised and

alarmed, instead of seeking safety in flight, they make a dead halt, swell out their body, making it hard and elastic, and distil this humour from its surface in augmented quantities. They also make efforts to bite, without, however, inflicting any injury. The direct application of the fluids proceeding from the common toad to the human skin is innocuous, and the idea that it confers a poisonous quality upon vegetables, fruits, and mushrooms, is entirely groundless.

The process of spawning in the toad is carried on much in the same way as in the frog. In the latter the ova appear imbedded in a glairy continuous mass, which has been compared to a cord or chaplet: in the toad two of these cords appear together, the united length of which would extend to about twenty feet. Ten or twelve days after deposition, the eggs acquire double their volume; the tadpoles issue forth about the twentieth day, and acquire their gills two or three days after.

Though the taste is not likely to become prevalent, there is no doubt that toads have been made familiar pets. Mr Pennant gives a curious account of one having lived in a kind of domestic state for the space of more than forty years, and of having been, in a great degree, reclaimed from its natural shyness and desire of concealment. On the approach of its master, and on the lighting of the candles at night, it left its retreat, and came to demand its regular evening meal. It grew to a very large size, and attracted many curious visitors. It was often brought to table, and fed upon various insects, which it seized with avidity, without being embarrassed by the presence of company. Its favourite retreat was beneath the steps of the house-door; and it had all the appearance of surviving many additional years, when it was attacked and destroyed by a raven.

But the most curious trait in the history of the toad, is its alleged power of being encased and buried for a long period of time without food or respiration, and of reviving again when reintroduced to light and air. Not that the toad is singular among the Batrachia for this faculty, for its congeners are likewise celebrated on account of it. Nor would it appear to be confined to this order, for similar stories are told of serpents, and even of fish, insects, &c. The attention of the French academy was directed to this subject about the year 1771, from its having been stated, that upon pulling down a wall of a mansion belonging to the Duke of Orleans, and which was forty years old, a toad which proved to be alive, was found in it, its hind feet being actually entrapt and imbedded in the mortar. Stimulated by the interest which this story excited, M. Herriault, in presence of the academy, enclosed three toads in as many boxes, surrounding them with a thick coating of plaster, and deposited them in an apartment of the academy. Here they were left untouched for eighteen months, when, on being examined, two of them were found alive, and the third dead. The former were re-enclosed, and on a second examination some months after, were found dead. The animals were completely impacted and imbedded, without leaving any space for surrounding air. Notwithstanding the apparently conclusive nature of these experiments, the possibility of such long endurance was still denied by many,—the more so, as the fact was as inexplicable as extraordinary. Dr Edwards, however, performed somewhat similar experiments in Paris in the year 1817, by shutting up toads effectively in plaster, when he found that they lived for a long period; and additional light was thrown upon the subject by that observer discovering, that when the plaster was made impervious to air, as by sinking the whole mass in water, the toads speedily perished. From this it follows, that owing to the porosity of the plaster, a portion of air still penetrates to the imprisoned toad, sufficient to maintain its vital functions in that low state in which we often see these reptiles during hybernation, or when completely frozen. The importance, under these circumstances, of the cuticular re-

Batrachia
Ranidæ.

Batrachia.
Ranidæ

spiration already mentioned, is obvious. Analogous phenomena are observable in other classes of the animal kingdom. Thus, the reviving powers of the *Rotifer redivivus*, though so astonishing, are now undisputed; and no one doubts Franklin's anecdote of the apparently dead flies, which he took from a fresh-drawn bottle of Madeira, and revived in the sun. Many drowned insects, to all appearance dead, are made to renew their vital powers when sprinkled over with dry warm sand, or pounded plaster; and it appears that in like manner, a certain feeble life, capable under altered circumstances of quick and strong increase, lingers long in many reptiles.

The great majority of the instances of imprisoned toads and frogs is said to have occurred in growing trees, hard wood, coal, and in sandstones and other rocks not of a very dense or impenetrable consistence. The fact has been long and frequently alleged, and the difficulty of accounting for it forms the chief ground of the prevailing scepticism. The wonder produced is forcibly though quaintly expressed in a Latin inscription written in letters of gold, framed with a coat of arms, and hung over a mantle-piece of sandstone, formerly in Chillingham Castle. In this sandstone there was a deep excavation, believed for ages to have been the living tomb of one of these creatures. We give a translation of a part of this document.

Hither, Stagyrile!
If you would see a phenomenon more wonderful than Euripus,
Come hither;
Let seas ebb and flow as they may, and let him be a lunatic
Who despoils the moon of her honours.
Behold here a novelty, such as neither Africa presents to thee.
Nor the Nile with her fabulous sands;
A fire and pure flame
Existing, though shut out from vital air,
From the dark recesses of the cut rock which you see,
The hands of the obstetrical stone-cutter gave light
To a living toad!!

In illustration of this alleged phenomenon, we shall adduce but a single recent instance out of many. On the 25th of July 1832, four men made affidavit, "that they were astonished, on splitting a large block of millstone grit on Stainmore, more than a ton weight, by a living yellow frog springing out of a cavity in the centre of the said solid rock, where it had been as closely imbedded as a watch in its outer case, without any communication with the surface nearer than eight inches. This frog was conveyed to Brough, Westmoreland, and given to Mr Rumney, surgeon, in whose possession it now (Jan. 21, 1833) continues in a healthy living state."

We have already mentioned, that however disgusting may be their qualities in the apprehension of many, toads are eaten greedily by savage tribes, and not seldom, though unwittingly, by the more fastidious inhabitants of the gay and splendid capitals of Europe. We now proceed to allude more particularly to a few of the species.

The common toad (*B. vulgaris*,—*Rana bufo*, Linn.) is of a russet or brownish-gray colour, sometimes olive, and even blackish. It is covered with numerous round tubercles on the back, and with smaller ones beneath. The hind feet are semi-palmated. It is found throughout Europe (most abundantly in its western parts), and is common in this country. It usually sojourns in obscure and sheltered places, and passes the winter in holes which it finds or makes for itself. It spawns in water in March and April; the ova are very small and numerous, suspended in two cords of transparent jelly. The tadpole is blackish, and remarkably small when it loses its tail and acquires its feet. The branchial aperture is on the left side. This toad is long lived, fifteen years being assigned as not unfrequent. Its cry has a distant resem-

blance to the barking of a dog, and during summer it croaks feebly.

Many toads possess a strong disgusting smell. Of this kind are the *rush toad* (*Rana hyla*, Gmel.), of which the colour and size much differ from those of the common toad, the cushions behind its ears being somewhat less. Its hind feet are not at all webbed, and it has a pouch or sac under its throat. Its pace differs from that of most of the toad tribe, as it runs nearly after the manner of a mouse, with the body and limbs somewhat raised. It is chiefly a nocturnal animal. The ova are contained in two cords; and the evolution of the ova is so speedy, that the tadpoles liberate themselves in the space of five or six days. During spring it frequents places overgrown with reeds, and croaks loudly. When handled or irritated it pours forth its cutaneous exudation, and squirts its other fluid to a distance of three or four feet, and thus diffuses an intolerable odour, resembling the smoke of gunpowder, but stronger, and so permanent, that if it fall upon furniture it cannot be got rid of for months. Analogous to, if not identical with the preceding, is *B. calamita* of Laurenti, the *natter-jack* of British Erpetologists,—*mephitic toad* of Dr Shaw. In general appearance it resembles our common toad, but the eyes are more projecting, with the eyelids greatly elevated above the crown, and there is a line of bright yellow along the middle of the back. This reptile was first remarked as British by the late Sir Joseph Banks, in Lincolnshire, and has since been met with on many heaths near London, as well as in Cambridgeshire and Norfolk. Except during the spawning season, it appears to affect dry and sandy districts. It is of much more active habits than the common toad, its pace "being a kind of shuffling run."¹ It never leaps. The *brown toad*, *B. fuscus*, Laurenti, is also distinguished by an offensive discharge; but in addition to the gunpowder-smoke smell, and overpowering it, there is an extremely strong odour of garlick or onions, which produces the same effects upon the eyes as do these vegetables. The whole of the skin of this animal is nearly smooth, and the hind limbs are long and deeply webbed. It leaps well, and prefers the neighbourhood of water. Its ova are deposited in a single cord, which, however, is thicker than the double one of the common toad. The tadpole of this species arrives at a great size before it attains its complete form, so that, according to Roësel, it is considered by the country people as a kind of fish, and is eaten accordingly. The *variable or green toad*, *B. variabilis*, Cuv., *Rana variabilis*, Gmel. and Pallas, *B. viridis* of Schneider and Shaw, is a third species, likewise characterized by a most disagreeable smell, resembling that of the rank and deadly nightshade, but more powerful, and soon contaminating any close apartment. This kind is a native of Germany, the south of France, and other parts of Europe. It derives its specific name from the tints of its colour undergoing striking changes as it sleeps or wakes, or is exposed to sun or shade. It is called the green toad from its spots being of that colour. Pallas's account of it is as follows: The general colour is pale or whitish, becoming in hot sunshine entirely gray; when asleep the spots only appear gray, and when torpid the general hue is flesh-coloured.

The *obstetric toad*, *B. obstetricus* of Laurenti, is a small grayish reptile which inhabits France, and affords an example of a very curious instinct. The process of spawning is not conducted by this species in the water, but on land, and there the male assists the female to get rid of her eggs, which amount to about sixty. These he attaches in small bundles to his thighs by means of an adhesive fluid, and for weeks carries them about with great care. When the young are ready to escape, he seeks some stagnant wa-

Batrachia.
Ranidæ

¹ Jenyns's *British Vertebrate Animals*, 303.

Batrachia.
Ranidæ.

ter, and there deposits them in safety, the tadpole soon issuing forth, and swimming immediately. The *prickly toad*, *B. spinosus* of Daudin, which derives its name from strong projections on its tubercles, seems also to possess a singular peculiarity. It is never met with on the surface of the soil, and is only procured by means of the plough. The country people are persuaded it never leaves its retreat voluntarily; and Daudin suspects that it deposits its ova in the earth, in humid places, near the subterranean sources of water.

Most of the toads of tropical climates are remarkable for their great size. Of this we give an instance in the *marine toad*, *Rana marina*, Gmel., a native of South America, the length of whose body extends to nearly a foot. It is also remarkable for its *post-aural* projections, which are an inch long, and oval shaped. The feet are not webbed; the toes are terminated with round knobs, and furnished with short claws resembling the human nails in miniature. There are many other recorded species of toads proper, on which, however, we cannot dwell; and we now proceed to several genera which have recently been separated from the group.

GENUS BOMBINATOR. This genus differs from the other toads only in having the tympanum, or soft covering of the ear, hid under the skin. **RHINELLA** of Fitzinger (**OXYRHYNCHUS** of Spix) is distinguished by a prolonged muzzle. (See Plate VI., fig. 4.) M. Gay has lately informed us (*Ann. des Sc. Nat. Avril* 1836, p. 224) that in Chili there is a genus allied to *Rhinella*, consisting of several agreeably-coloured species, which are always viviparous. In the same locality he made a similar remark regarding several species of snakes. To these two genera succeed the **OTILOPHA** of Cuvier, which has also an acute snout, and on each side of the head a projecting crest extending to the gland called parotid. In the genus **BREVICEPS** of Merrem (part of Fitzinger's genus **ENGYSTOMA**), neither the tympanum nor parotids are apparent; the body is oval, the head and mouth are remarkably small, and the feet scarcely at all webbed. (See Plate VI., fig. 5.) We shall here introduce a very few species belonging to these genera.

To the genus *Bombinator* belongs *B. bombinus* (*Rana bombina*, Gmel.), which is the smallest and most aquatic of the European toads. It is gray or brown above, blackish blue with orange spots beneath. The hind feet are completely webbed, and nearly as long as those of frogs, so that it leaps nearly as well as they do. It affects morasses. Of the genus *Rhinella*, Spix has depicted and described five species, most of which, according to Cuvier, it is difficult to distinguish from the proper toads. The *mitred toad* of English writers, the *margaritifera* of Gmelin, is usually adduced as a type of the genus *Otilopha*. It is a native of Brazil, and about the size of the common toad; it is rufous brown above and whitish beneath, beset with numerous small tubercles of a bluish or pearly cast, whence the French name *crapaud perlé*; but its principal characteristic is the subtriangular form of its head, the sides of which, beyond each eye, project into an angular protuberance. From the nose likewise an elevated white line runs along each side of the head, over the shoulder, to the sides; the fore feet are unwebbed, the hind are partly so. Genuine specimens of the genus *Breviceps* present animals not a little singular in their forms. Such are the *short-headed* and the *indistinct toad* of British authors, the *Rana breviceps* and *R. systoma* of Schneider. They are oval-shaped like eggs, with scarcely any projecting head; and one of them has actually been called the *headless toad* (*Rana acephala*, Schn.). The *short-headed toad* is a very small animal, about half the size of the common toad; the head is completely blended and incorporated with the thorax, and the surface is rather wrinkled than tuberculous. It is a native of Africa. *R. systoma* comes from the East Indies, and has a thick rounded

body, with a head so lost in the general outline that the mouth is scarcely apparent; the legs, too, are peculiarly short, and appear almost as if imbedded in the wrinkled skin of the sides.

We now advance to the genus *PIPA*, which is universally distinguished from the toads. Its generic characters are the following: The body is flattened horizontally; the head is broad and triangular; the tongue is so adherent that it appears to be wanting (it is often said to be so); the tympanum is hid beneath the skin; the small eyes are placed toward the margin of the lower jaw; the extremities of all the fingers are divided into four small points; and finally, the male has an enormously sized larynx, like a triangular osseous box, which encloses two moveable ossiculi which occasionally close the branchiæ. Of this genus, that well-known and most singular animal commonly called the Surinam toad (*Pipa Surinamensis*, Laurenti,—*Rana pipa* of Linnæus), may be taken as a type. It seems to have been introduced to the notice of naturalists at the close of the seventeenth century, and was first described by the celebrated Ruysch. It is one of the most uncouth and hideous of nature's creatures, and is especially signalized for some of the most extraordinary phenomena regarding the growth of its young which are to be found throughout the range of the animal kingdom. The size of the Surinam toad considerably exceeds that of our common species. The mouth is very wide; the hands are tetradactylous; the fingers long and slender, and each divided at the tip into four distinct processes, all of which, when narrowly inspected with a glass, are found to be again subdivided in nearly a similar manner. The web of the hind feet reaches to the tips of the toes. The male is rather larger than the female, sometimes attaining the length of seven inches. The back is studded with granules, which are somewhat more numerous and larger on the female; the skin round the neck, in both sexes, forms a kind of loose wrinkled collar. The general colour of both is a dark blackish brown. This reptile has been long celebrated for the manner in which its young are perpetuated; and on this account it has become the object of much attention. It was for a time supposed that the ova issued from the deeper seated parts of the back, and were then enclosed in small cells on its surface till they were regularly hatched. Later observations in correcting this mistake have demonstrated a not less peculiar history. The precise truth was first made known by Dr Fermin, who had an opportunity, during his residence at Surinam, to investigate the creature's structure in a more satisfactory manner than had previously been practicable. His account is, that the female *Pipa* spawns at the brink of some stagnant water, and that the male immediately collects and amasses the heap of ova, and after impregnation deposits them with great care on the back of the female, where they are received into cellules which at this period are open for their reception, but speedily close upon them. They are there retained to the time of their second birth, which happens in somewhat less than three months. During this period the cells gradually enlarge, till the young emerge from the back of the parent in a completely formed state. During the time of their concealment, however, they undergo the usual change which is effected upon their congeners, being first hatched from the ova in the form of a tadpole; and then, after gradually acquiring their perfect shape, losing their tail, and so forth, they are extruded from the cellules. This strange process has since been examined and verified by Camper, Spallanzani, Blumenbach, and other naturalists, and is now established as a phenomenon equally true as extraordinary. Fermin found the brood he observed amount to seventy-five, and the period of their extrusion as young *Pipas* occupied five days. When they had made their escape, the female, having rubbed the epidermis from her back on some hard substance, returned to land. This

Batrachia.
Ranidæ.

Batrachia. species lives in the fresh waters of South America, and sometimes in obscure houses in Cayenne and Surinam, where it is called *tedo* and *curucu*. According to Seba and Madame Mérian, the negroes of the colonies use its flesh as food.

Salamandridæ.

Spix has figured another species, *P. cururu* nearly resembling the above, which affects the bottoms of lakes in Brazil. That author assures us that the female does not receive and hatch its young in the alveola on her back. Another kind is preserved in the Paris museum,—a true *Pipa* according to Cuvier, from the Rio Negro. It is quite smooth, and has a narrower head than the common species. The baron names it *Pipa larva*.

FAMILY SALAMANDRIDÆ. NEWTS OR SALAMANDERS.

We have now reached a group of which the name has been celebrated from remote antiquity, and the history encompassed by fables in every age. "It was on the fortunate soil of ancient Greece, in the bosom of a wise and warlike nation, where imagination, favoured by a happy clime, exaggerated even the wonders of creative power, that the reputation of the salamander originated."¹ It was among that fanciful people that an obscure and changeful reptile was as it were consecrated to posterity by a fantastic but immortal name.

But the times of superstitious fiction regarding the once famous salamander are now for ever passed and gone, and it is only to be regretted that they have not carried along with them the ignorant prejudice which still remains respecting a few harmless reptiles. "The daughter of fire," with her "frame of icy crystal," is now nearly forgotten; and for unchanging love and unflinching courage, other and more fitting emblems have been long invented. The ancient story of the salamander enduring fire and extinguishing flame is now recognised only as an idle tale; and scarcely less so its faculty of poisoning vegetables, and its other pernicious powers. These gross errors being swept away, more room is left to investigate whatever is instructive in the history of those once widely abused, but really interesting creatures.

As the salamanders resemble in many respects the foregoing genera of the order, many of the details which have previously been stated equally apply to them. This remark relates also to the extraordinary metamorphoses they undergo, but with some striking variations. We here find examples of a species of reproduction not uncommon among fish, and met with, as already mentioned, among certain lizards. We allude to that mode of birth known under the name of *ovo-viviparous*. The mode we have been hitherto contemplating resembles that of birds in being strictly *oviparous*. The ova or eggs are extruded from the parent, and under the influence of heat the young are in due time hatched. In the salamanders, however, another stage intervenes. When the ova have arrived at the state in which, in the other Batrachia, they are wont to be expelled, in these they are retained for some time after their development has begun. The eggs are, in fact, never laid, but are hatched in the interior of the parents; so that they bring forth living offspring, although originally contained in eggs. These eggs, by a natural process, are deposited in certain bags, which are called *oviducts*. In the salamander there are five of these, each of which contains six, or eight, or more young, and there they are nourished by a peculiar fluid, and do not issue forth till they have undergone their metamorphoses, that is, have acquired their feet and other organs. They are deposited in or near marshes.

In our general remarks on the Batrachia, we traced, in a few words, the changes which take place in the respiratory system of this group. We saw that being first exercised in water, it was for a time precisely analogous to that of fishes; and that terminating on land, it perfectly corresponded with that of land animals. In the salamanders there is this peculiarity,—that while one section of them ere long become terrestrial in their structure and habits, another division continues aquatic for life. But so far as respiration is concerned, the same complete metamorphosis takes place in these latter as in the former; their gills vanish, regular lungs are completed, and yet the aquatic salamander, water-newt, or triton as it is sometimes called, continues a constant inhabitant of the water. The species are in fact habitual inmates of that element, and yet inhale the vital breath of heaven; and in this respect completely correspond to the cetaceous or whale tribes, with whose peculiarities, on a scale so greatly more gigantic, naturalists have been long acquainted. Like them they must regularly come to the surface, inflate their lungs, descend to their weedy homes, and after a time return again for air,—repeating this process as often as their exigencies may require. Peculiar characters distinguish the circulating system of the Cete, as compared with that of other Mammalia; and we have little doubt that parallel features occur among the tritons, although we are not aware that this point has been as yet investigated.

Batrachia.
Salamandridæ

When speaking of toads, we took occasion to make a few remarks on the cuticular secretion, for which they, in common with other Batrachia, are remarkable. The salamanders have on this account been still more celebrated; and there seems no reason to doubt that the fable of their withstanding the effects of fire has originated from this peculiarity. The humour is in them found to possess more concentric virtue, having withal a more offensive odour, and a more acrid taste. Count Lacépède says, that if a drop of it come in contact with the tongue, it produces the sensation of burning; so that it really proves a defence against many animals which would otherwise devour them. It is more especially when they are irritated and alarmed, and particularly if exposed to fire, that they distil the secretion in quantities, and envelope themselves in a damp covering, which, for a brief period, might possibly prevent their being consumed. Hence, then, may have originated the ancient opinion that these animals could live not only on land and in water, but also in fire; and from the slender germ of that same peculiarity has no doubt spread the monstrous statement of Pliny, that these creatures infested the herbage of a country to such a vast extent as even to cause the extinction of entire nations!

Another remarkable peculiarity of the salamanders, more especially of the aquatic kind, which has been successfully elucidated by Spallanzani, is common to them, and in some measure to the tadpole state of the other Batrachia. We allude to that surprising power whereby, when repeatedly deprived of even an important portion of their body, that portion is as frequently renewed. This property is not unknown among some of the lower orders of creation, but in none is it more striking than in these reptiles. Thus, in the triton, the whole limb may be removed, and by and by we find it completely restored, and furnished with perfect bones, muscles, nerves, &c. In other instances an eye has been extracted, and speedily a new and perfect one is found to have supplied its place. These renewals are more complete than such as take place among the true lizards, formerly alluded to.

The salamander group are distinguished by the following peculiarities. They have an elongated body, four feet, and

¹ Griffith's *Animal Kingdom*, ix. 464.

Batrachia. a lengthened tail, which gives them a general resemblance to the lizards. Their head is flat, and the ear entirely hid in the flesh, without any apparent tympanum, there being only a small cartilage over the external aperture. Both jaws are furnished with numerous small teeth, and two similar rows occur upon the palate. The tongue resembles that of frogs, but there is no third eyelid. They have a skeleton with fourteen dorsal vertebræ, and remarkably small rudiments of ribs, but without any osseous sternum; the pelvis is simply suspended from the spine by ligaments. They have four fingers and five toes. As we have already stated, they respire like the preceding genera. The arms of the tadpole are developed before the legs, contrary to what happens in the animals already reviewed.

Salamanders are divided into the terrestrial and aquatic. We commence with the former.

GENUS SALAMANDRA, Laur. Terrestrial salamanders. (See Plate VI., fig. 6.) In their perfect state these reptiles have a round tail; they remain in water only during their tadpole state (which is brief), or while in the act of reproduction. Their ova are inclosed in oviducts.

These salamanders, though not unfrequent in Europe, and in warmer regions, seem never to have been observed in Britain. They take up their abode in damp ground, and amidst brushwood, in ditches and shady places, in subterranean caverns and among old ruins. They are feeble, timid, stupid creatures, which live on worms, snails, flies, and other insects, and apparently on rich mould. They appear almost entirely deaf and dumb, and show no dread either of man, or of other animals stronger than themselves. If thrown into water, they immediately attempt to escape from it. They are capable of enduring most serious mutilation without apparently suffering from it; if, however, they are plunged into vinegar or alcohol, or are sprinkled with salt or tobacco, they are killed in a moment. We may now enumerate a few of the species. The *spotted salamander*, *S. maculosa*, Laur., of the usual length of six or eight inches, sometimes more, is one of the largest, and most widely spread through Europe. It is of a shining black colour, with two bright yellow stripes on its flanks, and of a livid blue colour beneath. It has conspicuous glands (parotids) behind its occiput, and along its sides are rows of tubercles, from whence, when alarmed, a milky humour flows, bitter to the taste, of a strong smell, and injurious to the life of very small animals. Its tail is of a roundish or cylindrical form, tapering to the extremity. It affects humid places, and retires into subterranean holes, under large stones and roots of trees. The brain of this reptile is said to be so small as not to equal the diameter of the spinal marrow, and its perceptive powers are proportionally dull. The *black salamander*, *S. atra*, Laur., is not above half the size of the foregoing; it is black, and devoid of spots above, and of a yellowish hue beneath. It is rare in France, but is found in the Alps, and is abundant in the mountainous regions of Southern Germany. (See Plate VI., fig. 6.) The *funereal salamander* (*S. funebris*) is six or eight feet long, of a deep-brown colour. It was observed by Bory St Vincent in the hottest and dampest parts of Andalusia. This species issued in dozens from their retreats at night, and speedily advanced towards destruction near the bivouac fires, by which they were attracted. Into these they would apparently have themselves advanced, had not the soldiers cast them amid the flames, where they remained for a few moments as if unhurt, thus far supporting their incombustible reputation. We need scarcely add, however, that they very speedily died *roasted*, as any other small animal would have done under a similar predicament.

Among the foreign salamanders a great number inhabit North America; and these are said to be destitute of the occipital glands. Palisot and Bosc have each described a new species. Thunberg has also discovered one in Japan,

to which the natives ascribe medicinal virtues of the most valuable kind. The *spectacled salamander*, *S. perspicillata* of Savi, has only four toes on the hind feet. It is black above, and yellow spotted with black beneath, with a yellow line between the eyes. It is found in the Apennines.

GENUS TRITON, Laur. Aquatic salamanders. We now turn to the aquatic group, commonly called newts, which have a tail always compressed vertically, and pass a great portion of their lives in water. (See Plate VI., fig. 7.) These are the animals experimented on by Spallanzani, and so celebrated for their reproductive powers. Another faculty, scarcely less singular, is that which M. Dufay has recognised them as possessing,—we mean their power of remaining frozen for a length of time in ice without mortal injury. Their ova are fecundated by the milt being mixed with the ambient water, and penetrating with it into the oviducts. After a certain sojourn there, the young issue in long gelatinous cords, from which they do not effect their escape till several days after their extrusion. The branchiæ continue for a longer or shorter period in different species. Few have been accurately observed in Europe, and doubts remain about their specific determination, because they change their colours with their age, and differ according both to sex and season. The crests and other ornaments of the males, also, are only fully developed during spring. If winter surprises them still wearing gills, these parts are then maintained throughout the colder season, and even continue to increase.

The following are species which have been accurately characterized. The *marbled salamander*, *S. marmorata*, Lat. (*Triton Gesneri* of Laurenti), has the skin chagrined, pale green above, spotted with large irregular brown blotches, and brown spotted with white beneath. A red line runs along the back, which in the male forms a kind of crest, marked with black spots. The *crested triton*, *S. cristata*, Lat., has the skin chagrined, brown above spotted with black, and orange beneath similarly spotted; the flanks are spotted with white. The crest of the male is high, acutely serrated, and embroidered with violet during the love season. This is our great water-newt (*T. palustris*, Flem. and Jen.), by no means uncommon in Britain during summer in ponds and ditches, and sometimes found in autumn out of water, in damp and shady situations. M. Bibron, who lately read a paper on these tritons to the London Zoological Society, stated that he had found this and the preceding species indigenous to Britain; and that the distinguishing characteristic consists in this, that in the crested species the upper lip is so largely developed that it overlaps the under one posteriorly when the jaws are closed, a condition never present in the *marmorata*. The *spotted triton*, *S. alpestris*, Bechst., has a chagrined skin, and is slaty and brown coloured above, and orange or red beneath; whilst *S. punctata*, Lat. (*T. punctatus*, Bonap.), has a smooth skin, light brown above, pale reddish beneath, and spotted everywhere with black. The crest is festooned, and its toes somewhat enlarged, but not webbed. This is the common (or smaller) water-newt of Britain. It is subject to considerable variation, and is often found on land. A third British species is the striped eft, *T. vittatus* of Gray. Finally, *T. palmata*, Lat., is brown on the back, black and brown on the head, lighter on the flanks, and spotted with black. The male has three small crests on its back; the toes are dilated and webbed, and the tail terminates in a slender membranaceous fin. North America is rich in aquatic salamanders; but our knowledge of these, as of many European species, is too obscure to admit of their precise classification. Baron Cuvier has well remarked, that a good monograph of this interesting group, with accurate plates, is a great desideratum.

We have now to conclude the present article with a few brief notices of certain very remarkable genera, some of

Batrachia.
Salamandridæ.

Batrachia.
Salamandridæ.

Batrachia. which differ considerably from all the members of the two preceding families, while others are by no means remotely allied to the salamanders. They are all aquatic; and while some lose their gills at so early a period as to have misled observers into the belief that they never at any time possessed these organs, others retain them throughout their lives, even to the last moments of internal lungs,—thus exhibiting, as we observed at the commencement of our treatise, the only truly amphibious animals of the vertebrated kingdom.

Genus Menopoma.

a. No apparent branchiæ.

GENUS MENOPOMA, Harlan; *Abranchus*, ejusd. We have here a form resembling that of the salamanders. The eyes are obvious, the feet well developed, and there is an orifice on each side of the neck. Besides the range of delicate teeth around the jaws, there is a parallel range upon the anterior portion of the palate. The only species known is the great salamander of North America (*S. gigantea*, Barton), called Hellbender in the United States. It measures from fifteen to eighteen inches in length, the colour of a blackish blue, and dwells in the rivers of the interior, and the great lakes.¹ (See Plate VI., fig. 8.)

GENUS AMPHIUMA, Garden. The species of this genus have also an orifice on each side of the neck; but the body is much lengthened, and the legs and feet but slightly developed. Their palatine teeth form two longitudinal rows. *Amph. tridactylum*, Cuv. is distinguished by three toes to all the feet.² Another species, *Amph. didactylum*, (*Amph. means*, Garden and Harlan), has only two toes. The body is long and cylindrical, the head depressed and obtuse; the tail compressed, with a sharpened ridge above, but blunt below. The fore feet are formed like tentacula. The colour is blackish gray above, and pale beneath, without spot or stripe. The observed size varies from six inches to two feet. This species inhabits ponds in the vicinity of New Orleans, and is met with in other parts of the southern states. It is sometimes found deeply sunk in mud, lying concealed like an earthworm, even at the depth of several feet. It is greatly dreaded, though without any reason, by the negroes, who name it the serpent of Congo.

b. Branchiæ apparent and persistent.

GENUS AXOLOTUS. The only known species of this genus, which we may name *Ax. pisciformis* (the specific title bestowed by Shaw), so entirely resembles the larva state of an aquatic salamander, that it is even yet regarded by some as an incompletely reptile. It was so regarded by Baron Cuvier in his contribution to Humboldt's *Voyage*,³ and even in his latest work he yielded rather to the opinion of others than his own conviction. "Ce n'est encore qu'avec doute que je place l'axolote parmi les genres à branchies permanentes, mais tant des témoins assurent qu'il ne les perd pas, qui je m'y vois obligé."⁴ The species in question measures from eight to ten inches in length, and is of a gray colour, spotted with black. It has four toes to the anterior feet, and five to the hinder, and there are three long tufted branchiæ on each side. (See Plate VII., fig. 1.) It inhabits the lake on which the town of Mexico stands, and is naturally subjected at times to a low temperature. The specimens brought home by Mr Bullock were from an elevation of 8000 feet. That collector informed us that at certain seasons they stock the markets, and are eaten in great quantities by the peasants. Sir Everard Home has published an account of their anatomical structure. He is

decidedly of opinion that they are not larvæ, but completed reptiles.⁵

GENUS MENOBRANCHUS, Harlan; *Necturus*, Rafinesque. Here there are only four toes to each foot. (See Plate VII., fig. 2.) There is a single range of teeth on the intermaxillaries, and another, parallel, but more extended, on the maxillaries. The best-known species is *M. lateralis* (*Triton lateralis*, Say), a large reptile which sometimes attains the length of two or three feet, and inhabits the great lakes of North America.⁶

GENUS PROTEUS, Laurenti. Distinguished by having three toes to the anterior feet, and only two to the hinder. The only known species is *P. anguinus* (*Siren anguina*, Schneid.), an animal resembling an eel with legs, of a pale rose or flesh colour, and measuring from ten to twelve inches in length, with a diameter seldom exceeding half an inch. The muzzle is depressed and elongated: both jaws are furnished with teeth, and the tongue is free in front, but not very moveable. The eye is excessively small, and covered over by a kind of tegument. The ears are also covered over more substantially, as among the salamanders. Besides the internal lungs, there are three feathered gills or branchiæ on each side of the posterior portion of the head. The skeleton resembles that of the salamanders, except that there are many more vertebræ, and fewer rudiments of ribs. The osteology of the head, however, is entirely different, and approximates that of the siren. The heart, composed of a single ventricle and auricle, is placed between the fore legs, and the lungs have the form of simple slender tubes, terminated by a vesicular dilatation. This truly remarkable reptile is found occasionally in a noted and romantic lake called Zirknitz (the Lugea Palus of the ancients), about six German miles from Labac, in the duchy of Carniola. From this lake, as extraordinary as its slimy inhabitant, the waters retire during the summer season by numerous subterranean outlets, leaving the ground fit for pasture and the cultivation of millet. In the month of October they return again with great force, springing out of the subterranean passages from a vast depth, till the lake is amply filled. It is situated in a hollow or valley, surrounded by rocky and wooded hills, in which are great caverns, and is supplied by rivulets running into it from the adjoining mountain regions. According to M. Schreibers, to whom we owe the first correct account of the proteus,⁷ its proper locality is Lake Sittich, one of several which communicate with that already named. Its more characteristic abode is probably among the subterranean canals which are known to connect together those peculiar lakes of Carniola. All its characters, in fact, present the aspect of a subterranean animal. It has a pale, bleached, ghost-like aspect, and its small, opaque, skin-covered eyes bear but small resemblance to the brilliant visual organs of other reptiles.

We come, finally, to the genus **SIREN**, Linn., in which the posterior legs are entirely wanting, and the anterior pair furnished with four toes. We have it in our power to state several particulars in the history and structure of a species of this genus from personal observation,—a mode of acquiring knowledge which, however desirable, has by no means been granted us in regard to the majority of the groups discussed in this exposition of the reptile race. We never, like Colonel Bory St Vincent, tossed a salamander into the fire,—we never, like Mr Waterton, rode on the back of an alligator,—we never waded waist deep, with Mr Audubon, among hundreds of these huge reptiles,—we never sailed, like Wordsworth's Highland boy, in a turtle's

Batrachia.
Genus
Siren.

shell,—and our practical experience, even of green fat, is far from extensive ;—but we have watched a siren from the far west ; and as the history of the species in question cannot fail to throw light on the nature and attributes of others to which it is related, and as it is in itself a very extraordinary and interesting reptile, we shall make no apology for the length of the following observations.

The Gardenian siren (*Siren lacertina*, Linn.), so named in remembrance of Dr Garden, by whom it seems to have been first observed, in its general form and aspect bears a great resemblance to an eel, but is at once to be distinguished from a fish by its anterior arms. The fine specimen long preserved alive by Dr Patrick Neill of Edinburgh was originally transmitted by Dr Farmer of Charlestown, South Carolina, to Dr Munro. It measured one foot five inches in length, and about four inches in circumference. (See Plate VII., fig. 3.) Its colour was deep blackish-brown, rather paler beneath, where it was partially tinged with a bluish hue, and marked all over with numerous small, irregular, pale, ashy-brown spots, not very perceptible except on a rather close inspection. The muzzle was blunt, depressed, sub-rounded or slightly square, and considerably narrower than the hinder portion of the head. The nostrils, which are inconspicuous, are placed near the anterior angle of the upper jaw. The head is broad and flat. The eyes are dim, of an obscure blue, and there is no very obvious distinction of colour between the iris and pupil, both appearing as if seen through a semi-transparent membrane. The gills consist of three fleshy peduncles, which increase in size from the first to the last. They are beautifully branched from beneath and along their lateral and terminal edges, and these little branches are divided and subdivided into still more minute ramifications. This elegant fringe-work forms the true gills, the central and fleshy stalks serving merely as their support. Beneath, and rather in advance of these bodies, are three vertical clefts, through which the water is ejected backwards from the interior of the mouth upon the gills, though with a much more languid and less perceptible action than in fishes. These clefts or branchial perforations are sustained and kept in separation by four arches, which Garden, Ellis, and Camper appear to have mistaken for gills, although both Linnæus and John Hunter took a more accurate view of the matter.¹

The general surface of this siren is very smooth and shining ; and if there are any scales, as some have said, they are not apparent to the naked eye. Towards the tail its form becomes thin and compressed, and that part is margined for several inches both above and below, as well as around its terminal point, by a narrow membrane or fin, which no doubt greatly aids its movements through the water.

The earliest notice of this singular reptile appears to have been communicated by Dr Garden to Linnæus through the medium of Mr Ellis in the year 1765. He described the simultaneous existence of lungs and gills, and concluded that it was a perfect animal, chiefly because there did not exist in Carolina any species of salamander, or other aquatic creature, of equal size, of which it could be regarded as the larva. It was in consequence of the information received regarding this species that Linnæus, though with hesitation, founded his order of *Amphibia meantes*, of which the most peculiar character consisted in there being “branchiæ et pulmones simul.” The great Swedish naturalist appears to have been particularly interested by the peculiarities of the siren ; for in his reply to Mr Ellis, acknowledging receipt of Dr Garden’s “very rare two-footed animal with gills and lungs,” he observes that nothing had ever

exercised his thoughts so much, nor was there anything he so greatly desired to know, as the real nature of so extraordinary a creature.

Although Ellis and Hunter wisely regarded the siren as a perfect animal, the propriety of this opinion was by no means universally admitted. Pallas, not perceiving that such metamorphoses as he supposed were undated impossible by the absence of any germ of the hinder extremities, even in the skeleton, still insisted that the siren was nothing more than the larva of a four-footed salamander.² A similar opinion was maintained by Hermann,³ Lacépède,⁴ and Schneider.⁵ About twenty years after the original discovery of the animal, Camper (in 1785) examined a specimen in the British Museum, the condition of which was so bad that he was unable to detect the lungs ; whereupon he took up and promulgated an entirely new view, according to which, without reference to the existence of feet, he declared that the siren was a fish. Gmelin, of course, immediately classed it with the eels, and it thus became the *Muraena siren* of his edition of the *Systema Naturæ* ! Whatever may be thought of Dr Garden’s skill as an anatomist, Camper’s conclusion was certainly somewhat precipitate, in the face of so great an authority as that of John Hunter.

In the year 1800, Baron Cuvier received a young siren from M. de Beauvois. The great French anatomist, whose splendid labours have thrown such a flood of light on so many obscure subjects of zoological science, was not likely to lose the opportunity of settling this still disputed point. In his first observations,⁶ and in an after and more ample memoir,⁷ he has, we think, successfully shown that both the proteus and siren are perfect, that is, completed animals, belonging to different genera of Batrachian reptiles, but quite distinct from either lizards or salamanders in any of their progressive stages. Yet the opposite opinion (so tenacious is error) does not continue without adherents. In an elaborate essay by two Italian authors, Sig. Configliachi and Rusconi, in which the siren is incidentally mentioned, these naturalists infer from analogy, that as the canal of the nostrils is not so perforated as to open into the interior of the mouth, so it must be incapable of respiring atmospheric air, and would speedily die if removed from its liquid element.⁸

Now, the value of the living siren observed by Dr Neill for six or seven successive seasons, consisted in this,—that it demonstrated *de facto*, what had been previously a matter of mere logical inference on the part of the anatomist. During the long period of its confinement no change whatever took place, either in its general aspect, or in the form or structure of the feet and gills. Had it been a larva, it would assuredly have lost these last-named organs during the time of observation. But the most curious result regarding this specimen was obtained accidentally, and happily illustrates the very point on which it was most desirable to obtain information. It is thus related by Dr Neill : “Although I certainly would not have made the experiment of the fragility of the siren, by throwing it on the ground, and although I would have hesitated to keep the animal out of the water for several hours, while I knew that respectable naturalists doubted if it would live more than a few minutes out of that element, yet it so happened that the creature on one occasion made of its own accord an experiment (if it may be so called) illustrative of both points. The water-box itself (in which the siren dwelt) was ten inches deep : it was placed on a plant trellis or shelf, close by the lower end of the sloping roof-sash of the green-house, and thus stood nearly three feet from the ground. At that pe-

ried the box happened to leak; and the gardener therefore filled it up with water between seven and eight o'clock in the evening, at which time the siren was seen safely lodged in the box. The door of the green-house was locked as usual over night, and before it was opened in the morning, the siren, to the great surprise of the gardener, was found lying on a footpath which passes round the exterior of the green-house. I was speedily apprized of the circumstance, and on examining the spot, we could most distinctly trace, by a shining glaze, derived from its skin, the passage of the animal through an edging of heath (*Erica herbacea*), and across a narrow flower-border, to a hole which he had scooped out under the brick-wall of the green-house, in escaping from within. The foundation of this wall, it may be remarked, had intentionally been made shallow, or near to the surface, for the purpose of permitting the roots of some shrubs, planted in the conservatory style within, to penetrate to the exterior border. We possess no data for fixing with certainty the number of hours during which the animal had been out of the water. The box, as already mentioned, being leaky, was filled near to the brim between seven and eight in the evening; it seems likely that this filling up had disturbed the animal, and that it had been enabled partly to crawl and partly to glide over the margin, while the water yet stood high, or early in the night; for the water had subsided five or six inches before morning. The escape of so much water had formed, of the soil below, a kind of sludge, probably somewhat analogous in character to the 'stiff clay' of its native swamps, in which it is said sometimes to burrow; and this must have greatly facilitated the first underground operations of the siren. Still, however, as the excavation made was not less than eight inches in depth, and nearly three feet in length, for the ascending aperture on the outside sloped at an angle of about 30°, it seems reasonable to conclude that the siren must have been several hours hard at work in forming so extensive a tunnel for itself. In further proof of its exertions, it may be observed, that a considerable part of the dark-coloured epidermis, or covering of minute indistinct scales, was worn off its snout, and the skin of the upper part of the back was in different places ruffled. The morning was very cold, and the mercury in a register-thermometer kept in the green-house had been as low as 33° Fahrenheit at one period of the preceding night. The animal was observed about seven A. M. lying doubled, or with the body bent round, but not coiled, on the footpath. He was exceedingly benumbed, being just able to show signs of life when lifted by the gardener. Considering the evidence of long-continued active exertions during the night, it seems reasonable to ascribe his almost torpid state when found, to the freezing cold which he had encountered when he had made his way fairly to the outside. When first restored to the watery element, the animal breathed hard, rushing to the surface, and opening his mouth with a wide gape to inhale air. He soon

after sunk down, and let several strings of air-bubbles escape. The branchiæ were doubtless to a certain degree dried, and thus obstructed; and it evidently took some time before they could freely perform their accustomed office. When, however, I again examined him several hours afterwards, he seemed perfectly contented to remain wholly under water; and on being touched, appeared as lively and as well as ever. The decorticated portions of the back and snout showed us the colour of the true skin below, which was of a pale leaden hue."¹

During the first year and a half of the siren's captivity at Canonmills, his box (filled with moss and water) was placed in a green-house, which merely excluded the severity of winter. He was very sluggish all this time, exhibited few signs of appetite, and from October to May entirely declined food. In the spring of 1827 he was placed in a hot-house intended for the culture of tropical plants, where the temperature was generally about 65°. He there became much more lively, and soon began his song, which, unlike the delusive voice of the ancient sirens, differed little from the croaking of a frog. He then devoured small earthworms with some avidity, and continued the practice without any lengthened intermission till his death in October 1831, after a captivity of nearly six years and a half, during which long period no structural change took place, nor was the slightest tendency to any such change discernible. The death of this reptile was occasioned, we doubt not, as Dr Neill supposes, by the drying up of the fimbriæ of the branchial apparatus, consequent on its having again escaped from its watery reservoir.²

We observed that the siren breathed air rather through the mouth than the nose, and expelled it in the same manner when put into the water, from which it may be inferred, that the nasal organ is in a rudimentary state (in the proteus it is said not to exist at all), so far at least as concerns the act of respiration. The eyes of the siren are dim and motionless; and we did not perceive that an increase of light caused any appearance of contraction or other change. Yet the sight must be tolerably acute, as in pressing a fly downwards under water with the point of a hair pencil, on the side of the vessel in which the reptile lay, it made a catch at the insect almost the moment it touched the surface, and immediately snapped it in two.³

Besides the species to which the preceding history and observations apply, two others are known to naturalists as inhabitants of the southern states of North America,—viz., the *Siren striata* of Le Conte, and the *Siren intermedia* of that author.⁴

(J. W.)

[N.B.—We are requested by the author of the article PHYSICAL GEOGRAPHY to state here, that he had been led to assert, on what he considered the best authority, that there were no serpents in Borneo (art. 405); but he has since learned from the Rev. Mr Horsburgh, resident in that island, that serpents are there abundant.—ED.]

REPTON, HUMPHRY, an eminent landscape-gardener, was born at Bury St Edmund's in 1752, and was educated for the mercantile profession. A course of bad success soon occurred to determine his ultimate calling. He was set up as a general merchant; but in no long time he met with losses which discouraged him. In 1783, he became confidential secretary to Mr Windham, secretary to the lord-lieutenant of Ireland; but a disgust at politics sent him back almost immediately to his country-house near Aylesham, in Norfolk. No less unfortunate was his connection in 1784 with Palmer, the introducer of the mail-coach system. He was obliged to take a small house at Hare Street in Essex, and to try some new means of livelihood. It was at this time that Repton began his successful career as a landscape-gardener. His good taste and elegant acquirements procured him constant employment. The works which he continued to publish on the subjects of his calling increased his reputation. At the time of his death, in 1818, there was scarcely a county in England which did not contain beautiful examples of his skill. Among the publications of Repton are the following:—*Sketches and Hints on Landscape-Gardening*, 4to, 1794; *Observations on Landscape-Gardening*, 4to, 1803; *Observations on the Changes in Landscape-Gardening*, 8vo, 1806; and a treatise *On the Introduction of Indian Architecture and Gardening*, fol. 1808. These works, accompanied by a memoir of the author, were reprinted in a collected form in 1840 by the late Mr Loudon.

REPUBLIC. See GOVERNMENT.

REQUENA, a town of Spain, in the province of New Castile, department and 64 miles S.E. of Cuenca. It occupies an elevated position among wild, rocky, pine-covered mountains, but has an extensive view over a rich plain. It is commanded by a castle, and has some traces of the walls that anciently encircled it and made it a place of great strength. The streets are straight, and the houses well built. The chief edifices are three churches and two former convents, the one now the town-hall, the other the barracks. In the principal square is a fountain. The inhabitants are chiefly employed in farming, and weaving of silks; also in dye-works, distilleries, flour-mills, and other manufactories. Some trade is carried on with Valencia and Castile in agricultural produce and manufactured goods. Pop. 10,404.

REQUISTA, a village of France, in the department of

Aveyron, arrondissement and 20 miles S. of Rodez. It has some trade in cheese, butter, and yarn. Pop. 4380.

RESHT, or RESHD, a town of Persia, capital of the province of Ghilan, stands in the midst of a wood, near the coast of the Caspian, 150 miles N.W. of Teheran. The streets are for the most part well paved, and the houses built in a superior manner. Large bazaars, partially open and partially roofed in, form the principal buildings in the town. Resht is the most unhealthy place in Ghilan, a province which is proverbial in Persia for its insalubrity. The chief manufacture of the town is silk-weaving; and the trade is very active, being carried on with Astrakhan, through the port of Enzillee on the Caspian, about 18 miles off; and by land with the principal towns of Persia. Near the port is a Russian colony of fishermen. Pop. about 60,000.

RESIN, or ROSIN, is the name commonly applied in commerce to the colophony, or solid residuum, obtained by distilling common turpentine, which consists of from 10 to 25 per cent. of the essential oil called spirit of turpentine, and the remainder of the brittle, brown transparent rosin, the composition of which is of a complicated nature, the following products being all obtained from this substance:—*Terebene, colophene, resinem, retinapha* or *toluole, retinyle* or *cumole, retinole, naphthalin, metanaphthalin*, besides others less known. All these substances are combinations in different proportions of hydrogen and carbon, and are called chemically *hydro-carbons*. Of late a valuable compound, resembling in most respects a vegetable oil, has been manufactured from rosin, and is now extensively manufactured both in Europe and America. It is about the colour of rape-oil, and is largely used in adulterating the common vegetable oils.

This rosin-oil is a combination of the retinapha $C^{14}H^8$ retinyle $C^{16}H^{12}$ retinole $C^{32}H^{16}$ and the metanaphthalin $C^{40}H^{16}$ and is separated from the other constituents by distillation. Several attempts have been made from time to time to use the gas which is formed by the decomposition of rosin-oil in the place of the coal-gas in ordinary use. The most extensive attempt of the kind was made at Southport in Lancashire, which formerly was lighted with rosin gas. The expense of its production in a neighbourhood where coal is plentiful has, however, led to its use being abandoned.

Resina
||
Resistance
of Fluids.

Rosin is completely soluble in alkaline leys, and is consequently available in the manufacture of the commoner kinds of soap, and is for this purpose very extensively employed. It is also used for a variety of purposes in the arts and manufactures, and in the composition of various pharmaceutical preparations, such as plasters and ointments, but is employed internally only in horse medicines.

Many plants of the nat. ord. *Conifera* yield turpentine and rosin abundantly; but so plentiful is the supply yielded by two species (*Pinus Tæda*, Lambert, and *P. palustris*, Lambert), which are amongst the commonest forest trees of the United States, that nearly all the turpentine used in this country is imported from America. The quantity received in the various ports of this kingdom in 1858 was 12,043 tons. It is imported in barrels, each containing about 2½ cwt., and is in colour and consistency much like honey.

There are other resins besides that procured from turpentine: they are usually termed gums or gum-resins. The following are the best known and most useful:—

Copal—Which is supposed to be yielded by some species of the genus *Hymenæa*, large tropical trees of the nat. ord. *Leguminosæ*. There are two kinds in commerce,—the Indian, which is received from Bombay in irregular-shaped fragments of a straw colour, and transparent when in thin pieces; the other is from Sierra Leone and other parts of Western Africa. This kind is in much larger lumps, varying in size from a hen's egg to that of a man's fist, and is imported in very large quantities. It is less valuable than the Indian variety, being coarser and less translucent: both are used exclusively in the manufacture of varnishes. There is a Brazilian species, but it is not well known. *Mastic* is the produce of *Pistacia lentiscus* (Linn.) It is brought chiefly from Mogadore and other North African ports. Two kinds occur in commerce; the better sort is in small roundish tears of a yellowish colour, slightly translucent. It is picked from the mastic bushes. The other sort is in irregular masses which have fallen from the branches to the earth, and are consequently mixed with many impurities. Both are used in the manufacture of the fine varnish used for varnishing pints, maps, and drawings.

Several other resins are used in small quantities in medicines, but are not of much importance. The imports of gum-resins in 1858 were:—*Copal* (also called *gum animæ*) 8900 cwt.; mastic, 1100 cwt.; olibanum, 120 cwt.; assafoetida, 1316 cwt.; guaiacum, 73 cwt.; benzoin, 104 cwt.; ammoniacum, 126 cwt.; euphorbium, 27 cwt. The less known ones were entered as gums unenumerated consequently their separate quantities are unknown. (T. C. A.)

RESINA, a town of the kingdom of Naples, in the province, on the shore of the bay, and 6 miles S.E. of Naples. It is built on the streams of lava and volcanic alluvium beneath which Herculaneum lies buried 70 feet deep. Numerous villas and country seats of the aristocracy of Naples stand in the vicinity; the chief of them is La Favorita, belonging to the Duke of Salerno. Resina is the most convenient place from which to begin the ascent of Vesuvius. Pop. 11,000.

RESISTANCE OF FLUIDS. *Resistance*, or *Resisting Force*, denotes in general any power which acts in an opposite direction to another, so as to destroy or diminish its effect. (See MECHANICS, HYDRODYNAMICS, and PNEUMATICS.) Of all the resistances of bodies to each other, there is undoubtedly none of greater importance than the resistance or re-action of fluids. It is here that we must look for a theory of naval architecture; for the impulse of the air, which is our moving power, must be modified so as to produce every motion we want by the form and disposition of our sails; and the resistance of the water, which is the force to be overcome, must also be modified to our purpose, in order that the ship may not drive like a log to leeward, but, on the contrary, may ply to wind-

Resistance
of Fluids.

ward; that she may answer her helm briskly, and be easy in all her motions on the surface of the ocean. The impulse of wind and water makes these elements ready and indefatigable servants in a thousand shapes for driving our machines, and we should lose much of their service did we remain ignorant of the laws of their action; they would sometimes become terrible masters if we did not fall upon methods of eluding or softening their attacks. We cannot read the accounts of the naval exertions of Phœnicia, Carthage, and of Rome,—exertions which have hardly been surpassed by anything of modern date,—without believing that the ancients possessed much practical and experimental knowledge of this subject. It was not perhaps possessed by them in a strict and systematic form, as it is now taught by our mathematicians; but the master-builders, in their dockyards, did undoubtedly exercise their genius in making those circumstances of form and dimension which were, *in fact*, accompanied with the desirable properties of a ship, and thus frame to themselves maxims of naval architecture in the same manner as we do now. The ancients had not made any great progress in the physico-mathematical sciences, which consist chiefly in the application of analysis to the phenomena of nature; and in this branch, in particular, they could make none, because they had not the means of investigation. A knowledge of the motions and actions of fluids is accessible only to those who are familiarly acquainted with the fluxionary mathematics; and without this key there is no admittance. Even when possessed of this guide, our progress has been very slow, hesitating, and devious; and we have not yet been able to establish any set of doctrines which are susceptible of an easy and confident application to the arts of life. If we have advanced farther than the ancients, it is because we have come after them, and have profited by their labours, and even by their mistakes.

Sir Isaac Newton was the first who attempted to make the motions and actions of fluids the subject of mathematical discussion. He had invented the method of fluxions long before he engaged in his physical researches, and he proceeded in these *sua mathesi faciem præferente*. Yet even with this guide he was often obliged to grope his way, and to try various bye-paths, in the hope of obtaining a legitimate theory. Having exerted all his powers in establishing a theory of the lunar motions, he was obliged to rest contented with an approximation instead of a perfect solution of the problem which ascertains the motions of three bodies mutually acting on each other. This convinced him that it was in vain to expect an accurate investigation of the motions and actions of fluids, where millions of unseen particles combine their influence. He therefore endeavoured to find some particular case of the problem which would admit of an accurate determination, and at the same time furnish circumstances of analogy or resemblance sufficiently numerous for giving the limits of those other cases that did not admit of this accurate investigation. Newton figured to himself a hypothetical collection of matter possessing the characteristic property of fluidity, viz., the *quæquaversum* propagation of pressure, and the most perfect intermobility of parts, and forming a physical whole or aggregate, whose parts were connected by mechanical forces determined both in degree and in direction, so that the determination of certain important circumstances of the motion of the parts might be rendered susceptible of precise investigation. And he concluded that the laws which he should discover in these motions must have a great analogy with the laws of the motions of real fluids; and from this hypothesis he deduced a series of propositions which form the basis of almost all the theories of the impulse and resistance of fluids which have been offered to the public since his time. It must be acknowledged that the results of this theory agree but ill with experiment, and

Retford. that, in the way in which it has been prosecuted by subsequent mathematicians, it proceeds on principles or assumptions which are not only gratuitous, but even false. But with all its imperfections, it still furnishes (as was expected by its illustrious author) many propositions of immense practical use, they being the limits to which the real phenomena of the impulse and resistance of fluids really approximate; so that when the law by which the phenomena deviate from the theory is once determined by a well-chosen series of experiments, this hypothetical theory becomes almost as valuable as a true one. It continues to be the groundwork of all our practical knowledge of the subject.

We know by experience that force must be applied to a body in order that it may move through a fluid, such as air or water; and that a body projected with any velocity is gradually retarded in its motion, and generally brought to rest. Analogy leads us to imagine that there is a force acting in the opposite direction, or opposing the motion, and that this force resides in or is exerted by the fluid; and the phenomena resemble those which accompany the known resistance of active beings, such as animals; therefore we give to this supposed force the metaphorical name of *resistance*. We also know that a fluid in motion will hurry a solid body along with the stream, and that force is required to maintain it in its place. A similar analogy makes us suppose that the fluid exerts force, in the same manner as when an active being impels the body before him; therefore we call this the *Impulsion of a Fluid*. And as our knowledge of nature teaches us that the mutual actions of bodies are in every case equal and opposite, and that the observed change of motion is only the indication and measure of the changing force, the forces are the same, whether we call them impulsions or resistances, when the relative motions are the same, and therefore depend entirely on these relative motions. The force, therefore, which is necessary for keeping a body immovable in a stream of water flowing with a certain velocity, is the same with what is required for moving this body with this velocity through stagnant water. A body in motion appears to be resisted by a stagnant fluid, because it is a law of nature that force must be employed in order to put any body in motion. Now the body cannot move forward without putting the contiguous fluid in motion, and force must be employed for producing this motion. In like manner, a quiescent body is impelled by a stream of fluid, because the motion of the contiguous fluid is diminished by this solid obstacle; the resistance, therefore, or impulse, no way differs from the ordinary communications of motion among solid bodies. Experiments on this subject have been made by Sir Isaac Newton, D. Bernoulli, Du Buat, Sir Charles Knowles, Euler, D'Alembert, S'Gravesende, Coulomb, Hutton, and Vince. A detailed account of the theories of those authors will be found in the article HYDRODYNAMICS, ii., c. 3.

RETFORD, EAST, a market-town, municipal and parliamentary borough of England, in Nottinghamshire, on the right bank of the Idle, here crossed by a bridge leading to West Retford, 33 miles N.N.E. of Nottingham, and 138 N.N.W. of London. It is well built and paved; and has a large, irregular market-place, with a pillar in the centre, occupying the site of a more ancient cross. West Retford is a smaller and more modern town; and South Retford is a name given to an enlargement of the town towards the south that has recently been made. The parish church of East Retford is a large edifice, of various dates and in various styles, surmounted by a lofty square tower; that of West Retford is smaller, but very elegant. In a suburb of the town called Moorgate stands a Gothic chapel of ease; and the other places of worship belong to Independents, Baptists, Wesleyans, and other dissenters. The town-hall is a handsome structure. A free grammar school, national and infant schools, a literary and scientific

institution, with a library, are founded for the instruction of the town; while an hospital, alms-houses, and various other establishments form the charitable institutions. Few manufactories of any kind exist here: the town is supported chiefly by retail trade with the surrounding country, the principal articles of commerce being coal, corn, hops, and dairy produce. Weekly markets and annual fairs are held here. The borough is governed by a mayor, three other aldermen, and twelve councillors; and returns two members to Parliament. Pop. (1851) of the municipal borough, 2943; of the parliamentary borough, 46,054.

RÉTHEL, a town of France, capital of an arrondissement in the department of Ardennes, on a steep slope on the right bank of the Aisne, 22 miles S.W. of Mézières. Its broad, straight streets are lined with houses generally ill built, and frequently only of wood. A large market-house, several churches, a theatre, and prisons, are the chief buildings of the town. The principal church is a remarkable building, formed by the union of two placed side by side; and it is decorated with bas-reliefs and other sculptures. Three ancient gates of the town still remain. Réthel has a college, agricultural society, chamber of manufactures, and court of law. It is a busy place, manufacturing leather, woollen cloth, and other articles, in which there is also an active trade. Pop. (1856), 7214.

RETICLE. See MICROMETER.

RETICULATION. Among the devices which man has invented for securing to himself the "dominion over the fish of the sea and over the fowl of the air," the net is conspicuous. Netting therefore becomes an art of some importance; and among the varieties of it, fishing-net making is the most important. Fishing-nets are simple but ingenious contrivances, admirably adapted to their use; for when wet they are easily dried, when torn easily mended. They offer little resistance when drawn out of the water, whereby the labour of hauling them is greatly diminished; the risk of their being overthrown or carried away by tides, currents, or storms is lessened; and the more shy fish are not so easily scared away as they otherwise would be by toils more densely wrought. The sand, the mud, the young fry and spawn, the small insects and other animals inhabiting the waters, find a free passage through the meshes, and thus much wanton destruction of animal life is prevented, whilst a larger abundance and a more regular supply of fish is obtained than by any other mode. Netting differs from weaving in this, that where the threads or cords cross each other they are tied into hard knots, so that each mesh is incapable of enlargement or diminution. The forms of nets vary according to the manner in which they are intended to act, and this is either by entangling the fish in their complicated folds, as in the *trammel*; receiving them into pockets, as in the *trawl*; suspending them by the body in the meshes, as in the *mackerel-net*; imprisoning them within their labyrinth-like *chambers*, as in the *stake-net*; or drawing them to shore, as in the *seine*. The parts of a net are the *head* or upper margin, along which the corks are strung upon a rope called the *head-rope*; the *foot* is the opposite or lower margin, which carries the *foot-rope*, on which in many cases leaden plummets are made fast. The *meshes* are the squares composing the net. The width of a net is expressed by the term *over*, as a *day-net* is three fathoms long and one *over* or wide. The *lever* is the first row of a net. There are also *accrued*, *false meshes*, or *quarterings*, which are loops inserted in any given row, by which the number of meshes is increased. To *bread* or *breathe* a net is to make a net. *Dead* netting is a piece without either *accrued* or *stole* (stolen) meshes, which last means that a mesh is taken away by netting into two meshes of the preceding row at once, thereby diminishing the net at any part. With respect to the tools used in netting, the *needle* is the instrument used for holding and netting the

Reticulation.

material to be netted; it is made with an *eye* E, a *tongue* T, and a *fork* F (fig. 1). The twine is wound on it by being passed alternately between the *fork* and round the *tongue*, so that the turns of the string lie parallel to the length of the *needle*, and are kept on by the *tongue* and *fork*. A short *needle*, about 4 inches long, should be set apart for *mending*. A *spool* or *mesh-pin* is a piece of wood on which the *loops* are formed, as in fig. 2; or it may be formed flat, as in fig. 3; the circumference of the *spool* determining the size of the *loops*. Each *loop* contains two sides of the square mesh; therefore, supposing that it be required to make a mesh 1 inch square,—that is, measuring 1 inch from knot to knot,—a *spool* 2 inches in circumference must be used. Large meshes may be formed by giving the twine two or more turns round the *spool*, as occasion may require, or the *spool* may be made flat, and of a sufficient width, having a portion cut away to admit the finger and thumb to grasp it conveniently (fig. 3). A pair of *round-pointed scissors*, so as to be carried conveniently in the pocket, and a *knife*, are likewise useful. To *return on your work* is when, in *breeding* a cylindrical net, you stop at any given point, turn your work and net back again, instead of going on round and round, as in forming the *regard* of the *hoop* net, which is a slit made in that engine, through which the fisherman introduces his hand to extract the fish caught therein, when he goes to *look* (*regarder*, French) what success he has had. *Taught*, tight; the twine is pulled *taught* when a knot is made. 2. The method of making the loop or stitch in netting can be taught, but it is not easy to describe it in writing. 3. The same may be said of *making accrues*. 4. The *bend-knot* is constantly required for uniting two ends of twine together, and it is made as shown in fig. 4, in which A and B are to be joined. 5. The art of *mending* is of great importance; for if the fisherman cannot mend an occasional rent, he will soon be obliged to have a new net. The amateur netter and game-keeper often neglects this part of the art of reticulation, and a bungling confusion of threads, drawn together anyhow, serving rather to increase the mischief, is substituted for a neat and efficient repair. In order to explain the method to be pursued, we will suppose that a net (fig. 5) has an injury in the middle of the space indicated

Fig. 1. Fig. 2. Fig. 3.

Fig. 4.

Fig. 5.

by the dotted lines. We must begin by *cutting* the net,—that is, the hole must be enlarged, not only by removing that portion which is actually torn, but by cutting into the sound parts. The parts to be cut away are marked by the transverse lines *b, a, a, a*; *c, b, a, a, a, d*, below the knots of the original net. It will be observed that, whereas at *a, a, a*,

Reticulation.

c, a, a, a, d, two sides of the meshes are cut, *one* only is removed at *bb*. In performing this manœuvre, the workman must have the net hung before him in its proper position,—viz., in the order in which the rows were netted, as in fig. 5. This requires attention, because if either of the sides *c* or *d* were uppermost, the mischief would be increased when he came to cut away according to the above instructions. The next thing to be done is to unpick the knots of the old meshes, *a, a, a, a, a, a*; but the lateral knots *c, d* must *not* be unpicked, for that would destroy the adjoining sound meshes; for the same reason, only *one* side of the meshes *b b* is cut. We must suppose, then, that the meshes represented by the dotted lines are entirely removed; the next thing to be done is to replace them. It is evident that this cannot be properly accomplished unless the inserted meshes resemble as accurately as possible those that have been removed. A practised hand will effect this without a spool; but some skilful workmen think that it is less troublesome, and that the required regularity of the meshes is better insured if a spool be used suitable to the meshes of the old net. Having filled a *small* needle with twine, make fast the end above the knot at K (fig. 5), hold the spool and needle in the usual way, and take up the loops L, M, N, as in common netting; when at N, lay aside the spool, and make the side NO. This is done by means of the *bend-knot*, the angle P being the *bend* or loop of the knot. The second row is now to be netted in the same way as the first, and so on with the rest, the single side at the end of each row being managed as at NO, and leading down to the row beneath. We have supposed the workman to have begun and ended this first row, netting from left to right; to work back the second row, he has simply to get on the other side of his net, or to turn the latter over, as may be most convenient, and thus to net on as usual from left to right, changing at the end of each row either the position of his net or of his own person. We shall next suppose that the required number of rows save one is completed; we must insert a *junction* row between the row QRST, and that of the old net VWXY. This is done without a spool, by making the side TV fast at V with a *bend-knot* round the loop of the old net at V; then the side VS, with a *bend-knot* at S, round the loop of the new piece at S: then the sides SW, WR, RX, XQ, QY, in the same manner. Care must be taken that these sides be of the same length as the sides of the other meshes. At the beginning K and the end Y of your work, leave ends *e, e* to prevent the knot slipping. In fig. 5 three rows have been removed; and it will be seen that those loops which have only *one* side removed are diagonally opposite to each other; and thus it is when an *uneven* number of rows is to be cut away; but when an *even* number is removed, those loops of which only one side is cut are at opposite angles of the orifice, but on the same side of the square. 6. *Oblong and square netting*.—If it be required to have a net with meshes setting in squares with their sides accurately at right angles with each other, like the squares in a sash-window frame, the following method is to be pursued. Net one loop for the first row, draw the spool out and net two loops for the second row, the additional loop being obtained by taking up that one loop which formed the first row twice, or, as it is technically termed, *by setting in a false mesh*. The second row will thus consist of two loops. Remove the spool, begin the third row, which is to consist of three loops, the additional one being gained as before. Continue thus adding a loop at the *end* of each row until you have made your half square as large as you require, the two *selvages* on each side of the netting forming two sides of the square; then, before you begin to form the other two sides of the square, net one row of *dead* netting,—i.e., do not increase or diminish anywhere; but at the *end* of the following rows set in a *stole* mesh,—i.e., take up

Reticulation.

Reticulation.

the last two loops of the row together. The net will at last be reduced to one loop again, and will, when stretched out, form a complete square, and all the meshes will stand square with each other. But supposing you want the net to be longer than it is wide, and yet the meshes composing it to be square, as in the other, you are to proceed as follows:—Form half a square as before, the length of one side of which will determine the width of the oblong to be made. When this is done, you must set in a *false mesh* at the end of one row, and a *stole* mesh at the end of the other row. Continue thus adding and diminishing *alternately*, until your oblong is of the required length, and this is ascertained by measuring the long side of the netting from the corner to the last knot. Finish off by taking two loops up at once at the end of each row. In the *oblong* you need not net a row of plain loops before you begin to finish off, as was done in the *square net*. Oblong and square nets, when worked as now directed, will when finished appear in the shape of a lozenge, and so will all the meshes of which they are composed; but when stretched out with the sides at right angles, each to the other, the whole net will assume its proper shape. It adds to the finished appearance of the net if, on making the last loop of the net, the spool be withdrawn before the knot is *taught*, and then draw the twine up; the last loop is thus as it were *absorbed*, instead of remaining there to spoil the neatness of the work. The single loop, too, with which the net was begun may have its knot sufficiently loosened to enable the workman to tighten up the loop and make it *vanish*, as he did at the other end. A little practice will make this clear. Many net-makers consider it a great saving both of time and twine to make their *hay-nets*, and the like, after this manner; besides which, the *selvage* thus formed along each side of the net affords sufficient strength without any additional cord to border it. 7. *How to net a round or cylindrical net without having to join*.—Net any given number of loops, and when you come to the end of the row, instead of turning the net over to net a second, keep the spool in the last loop, and with the needle pick up the *first* loop of the row just finished, and net into it in the usual manner, and thus the row will be united. Continue to take up each loop on your right hand in succession, as in ordinary netting, and thus go on netting round and round until you have obtained the required length. The rows will resemble the turns of a spiral spring descending from the top to the bottom. 8. *How to make a bag-net from a square*.—Net a piece of *dead netting* containing any given number of loops in the row, observing always an *odd* number, as 3, 5, 7, 9, 11, according to the proposed size of the bag; net double the number of rows that there are loops in the row save one, as 5, 9, 13, 17, 21. This done, draw the foundation string,—viz., the string on which you netted the *lever*, and fix it in the middle of your square, then net round and round it. The corner loops must be carefully worked for the first few rounds to make them set even. It is always in the workman's power to increase the circumference of the bag as he proceeds from the bottom to the mouth, by setting in *false meshes*. In doing this, however, he must observe regularity, and take care to insert his *quarterings* at equal distances, else the net will be lop-sided and distorted. 9. *Of joining two nets together*.—Apply one net on the other, supposing each to contain the same number of meshes in the rows to be united, and that the meshes are of the same size; then, with a spool a full quarter less in size than that on which the nets were *breaded*, net one row along the margins to be joined, taking up two loops on the needle,—i.e., one mesh of each net together; or if the object be to join the first with the last row of the same net, the two rows must be accurately placed one upon the other, by folding the net over on itself; then proceed as before. Sea-nets, such as those for herrings and mackerel, which

are made in *rands* or breadths, are joined rand to rand lengthways, or along the *selvages*. The former are composed of three breadths, each thirty-two yards long by fifty loops deep, on a spool three inches in circumference. At the close of each year the lowest rand, which goes deepest into the sea, is removed, and a new one joined on at the top of the net; so that the rand which was uppermost now becomes second, and that which was second is now the lowest. This latter is removed at the end of the next season, when the same rule is observed in replacing it, and so on every year; thus the whole of the original net is renewed every three years. This operation is called by net-makers giving the net a *new jacket*. Another mode of joining, and when performed carefully it is the neatest, is by uniting the two nets, or the two margins of one net, in the same way as the last row of the new piece is joined to the meshes of the old net in *mending*. The first-made side of the *inserted* or *joining work* must be twice as long as the rest, as also the last side of the suture; for they in fact are equivalent to *two* sides of a mesh.

The following description of specific nets will serve to furnish examples of the foregoing rules, and of the mode of *mounting* nets, which yet remains to be noticed:—The *casting-net* is netted round and round (see No. 7 in this article); the number of the loops for the *lever* vary, as well as their size, according as it is intended for *gudgeons*, &c., or *minnows*; in either case, it would be a great loss of labour if the whole net were made on one spool so small as it is necessary the lower part of the net should be. Spools, therefore, of different circumferences are used, diminishing gradually from the largest for the top, to the smallest for the *tuck*. The following will form a good-sized net for *gudgeons* and larger fish:—Fill the needle with double twine; net four rounds with a spool two inches and a half circumference on a *lever* of thirty-six loops; then use single twine, and in the fifth row set in twelve *false meshes*; net two rounds *dead netting*, and then set in *false meshes* in the same line with the others, having taken care to set in the *quarterings* of the fifth row to as to divide the circle into equal parts. Net two feet down on the first spool, then one foot down on each of seven other spools, each spool being an eighth of an inch less than the preceding one. Continue to set in *quarterings* in their proper places, and at the commencement of the *eighth* foot set in four additional *false meshes* equidistantly between the *original quarterings*, and continue putting in the *accrues* until you have netted a foot and a half more, having taken to your *eighth* spool at the beginning of the *ninth* foot; then net four rows *dead netting* in *double twine*; take your *ninth* spool, and net two feet six inches of *dead netting* for the *tuck*, the last two rounds in *double twine*. Have a stout line with leaden bullets threaded on it, and sew this line, with running stitches, through each mesh, along the lowest row of the net, the interval between each *lead* being two inches. This weighted margin is then turned upwards and inwards, and made fast to the *double twine-work* above the *tuck*, at about every foot of the circumference, by means of ratlines three inches long. The *lead-line* should be about a foot less in length than the row of the *tuck* to which it is sewn. The *leads* are made fast to the line by being tied at each end to prevent slipping and the holes should be bored as near the size of the line as possible. The *trammel* consists of three separate layers of nettings, and derives its name from its conformation (*trois mailles*, French), because it ensnares by *threefold meshes*. The three parts consist of two *out-wallings* and the *lint*; this latter is suspended loosely between the two former, it being made twice their length and twice their depth. The two *out-wallings* are of the same size. The length and depth of this net vary according to the service it is intended to perform, either in fishing or fowling; the same may be said of the

Reticulation.

size of the meshes; those of the *out-wallings*, however, are generally five times larger from knot to knot than those of the *lint*. All the parts should be netted *four square* (as *oblong* and *square* netting is sometimes called, see No. 6 in this article), the *lint* in twine as fine as may be consistent with the required strength, and the *out-wallings* with much stouter material in proportion. These, when finished, are to be *mounted*. Fix each of the four corners of one *out-wallings* to four pegs driven into the ground, which should be cleared of rubbish, &c. The *out-wallings* is to be stretched tight. Pass all round the *lint*, through each mesh, a stout line of twine as thick as that of which the *out-wallings* are made. This line, and likewise the *lint* at its four corners, is made fast to the four pegs; the former is drawn tight from peg to peg; but the latter, being longer and wider, hangs loosely. The meshes of the *lint* should be as equally distributed along the line as possible. Over the *lint* is applied the other *out-wallings*, the four corners of which are to be fastened to the four pegs. If the net is intended for fishing, a stout cord must be threaded with round flat corks two inches diameter, and half an inch thick, more or less. This cord is to be fixed along the *head* of the net by means of pieces of twine whipped two or three times round, and embracing the line of the *lint*, the margins of each *out-wallings*, and the cord itself. The twine is tied into a firm knot at those points where the cord meets the angles of the *out-wallings*' meshes. The floats are placed about six inches apart, and are pierced so as to embrace the *head-rope* firmly. This last is made fast down *each side* of the net, at the angles of the meshes of the *out-wallings*; but it has here no floats; it is extended along the bottom of the net, where it is called the *foot-rope*, and is weighted with small plates of lead rolled and beaten round it with a hammer, as a tag is fixed round a boot-lace, at about every three inches. The cord that thus surrounds the net must be bent into a loop at each end of the top of the net, for to these is to be made fast a *draw-rope* when the net is *shot*. Some net-makers also tie the three layers of net together at each angle of the meshes of the *out-wallings* throughout the area of the net, to give additional strength, and to prevent the *lint* getting *huddled* together at the bottom when suspended in the water or drawn along the ground. This net acts thus:—The fish or fowl passes through the large mesh of the *out-wallings*, strikes against the *lint*, which, hanging loosely, yields, and protrudes through the corresponding mesh of the other *out-wallings*, and thus forms a *cæcum*, into which the animal falls, and is entangled. The *hoop-net* consists of two parts; the *body*, and the *valve*, *funnel*, or *gullet*, which are united in the manner hereafter to be described. Begin with the *body* at its lower or pointed end, and work up to its entrance, thus: Net thirty-seven loops round on a spool four inches circumference, one row. Take a spool two inches circumference, and net twenty rows of *dead* netting. In the next row set in five *false meshes* equidistantly, then twenty rows of *dead* netting, then a row with five *false meshes*; repeat this manoeuvre; then net thirty-six rows of *dead* netting, and the next row in *double twine*; thus you have an upper and a lower row, as shown in fig. 5, the dotted lines representing the lower row. Cut off the thread which has worked the *upper* row, leaving an end; empty your needle, and wind on it the thread that proceeds from the *lower* row, and work on with the single twine as follows, taking care, however, to pick up only the loops of the *lower* row as you go round. Net on the same spool fourteen rows of *dead* netting, then at equal distances in the circumference of the fifteenth row set in eight *stole* meshes, then net two rows of *dead* netting, in the next row eight *stole* meshes in a line with the others; repeat this action three times more. After you have for the fifth time set in your *stole* meshes, net a row of plain netting; lay aside the two-inch spool, and take

a twelve-inch and net one row. The *valve* is now finished, and must be reflected inwards to gain its right position. You now take your needle, charged with single twine, and join on to that end which was left at the upper row where the valve issued from the *body* of the engine; with the two-inch spool net eleven rows of *dead* netting. In the next row set in five *false meshes* at equal distances each from the other, and continue to set in these at every third row eleven times in the same line. This done, make seven rows of *dead* netting, then one row on a four-inch spool in *double twine*. Through this last row a plant stick is passed, about six feet long, and bent into a *bow* (BBB, fig. 6); a

Reticulation.

Fig 6

piece of cord keeps the extremities in place, answering to the string of the archer's bow; the lower meshes of the net's mouth are strung on this cord. A weight is generally attached to the *bow* at its extremities, somewhere towards BB. Four hoops are lashed round the net at HHHH, to prevent its collapsing; these are larger as they proceed from the point to the mouth, and are made of *st* *cher* wood than the bow, the smallest being about one *in* *three* inches diameter, and the largest two feet.

Some *hoop-nets* have more than one *valve*. In that case the hoops must always be placed at the entrance of the *valves*, and many netters make a row of *double twine* at those parts, to give additional strength where there is most strain on the netting. The large loops at the bottom of the *funnel* are tied together in *fascies* of equal number of loops, to four lines, and these are made fast to another line which is threaded through the last row of meshes belonging to the point of the *body*, and which, being drawn tight, closes up the entrance at that part. All the lines are then tied to a support at P, and thus the net is kept extended. The principle of this engine is analogous to that of the common mouse-trap. When there is only one valve (as in fig. 6, V), the fisherman withdraws the fish by loosing the line that closes the body of the net at P; but when there are more valves than one, he makes a *regard* in the *body* between each hoop. A *regard* is thus made: Net round and round, and when arrived at the part wherein you wish to put a *regard*, *return on your work*; and when you again come to the place where you altered your mode of netting, return again; and thus continue until you have made the *regard* of sufficient length, then work round and round as before.

A *tunnel* for partridges is made like the hoop-net, but without valves.

The *trawl* is a very large and rapacious net, and much discussion has been held as to whether it should be permitted. It appears, however, that under proper restrictions it is not detrimental to the fisheries. This net is composed of two separate pieces, called the *upper* and the *lower leaf*; the meshes are about two inches square. For the *under leaf* or *blade*, net 160 loops in *double twine*, two rows; then with single twine net a plain row; in the next, set in a *stole* mesh at about the sixth mesh from the beginning, and another at about the sixth mesh from the end of the row; net three rows of *dead* netting, then set in *stole* meshes as before; repeat this once again, afterwards go on setting in

Reticulation.

stole meshes less frequently,—i.e., leave five rows of dead netting between, until the width of the *blade* is reduced to thirty-six meshes, then net about five feet for the *hose* or *ail* H (fig. 7). The *wings* are now to be set on to this *leaf*. For this purpose, you must begin working at the other extremity, or top of the *leaf*, as at T or t; net fifty-six loops and stop; return on your work; net again to the end of your row (the third), and here, quite at the extremity, set in a *false mesh*; but when, in the course of netting row after row, you come to the *false meshes*, do *not* take them up, but let them *hang*, as is shown at B and B of the *wings* W and W. At the commencement of every row which alternates with those to which you add a *false mesh*, at about three loops from the beginning, set in a *stole mesh*: thus the *false meshes* will always be on one side, and the *stole meshes* on the other side of the *wing*, which will thus be diminished at last to eighteen meshes. When this is effected, net two rows in *double twine*, not adding or diminishing. Thus one *wing* is done; net the other in the same way, and take care that the one is exactly the same as the other. The *under leaf* being now finished, we pass on to the structure of the *upper blade* (fig. 8). Net 180 loops in *double twine*, two rows; then with single twine forty rows of *dead netting*; diminish evenly and gradually from 188 to 160 meshes, taking notice that this reduction must be made before you come to a level with the *double rows* whence the *wings* rose in the other *blade*. Diminish from 160 to 36, as you did when working down the *lower leaf*, making the *hose* as before. The *blades* being now finished, must be joined together down their sides, as the sides of a sack are; and a rope, acting as a binding along the seams, is sewn on, in the same way as the *head-rope* of the *trammel*. Round the top of the *upper blade* a rope is strung through the meshes, and carried round the *bosom* BBB (fig. 7), being sewn to, and not threaded through, the *hanging false loops* of the *wings* W, W. The two *blades* are then sewn together at certain parts to form *pockets*, in the direction of A, A, A, A, A, A; o, o, o, o, o, o, being the orifices of the pockets. At L, L loops of rope are bent, to which lines are hitched for hauling the net out of the sea into the boat. The two *blades* or *leaves* must be *exactly* of the same length; for, when joined, the top row of the *wings* must be even with the top row of the back of the net or *upper blade*, and the *hose* should meet no less accurately at the bottom. When the *trawl* is in the sea, a long beam of about thirty feet in length, and seven inches in circumference, is lashed to the top of the net, keeping the *wings* and back extended from point to point. This beam is let into irons, called *trawl-heads*, at each extremity, which

Fig. 7.

Fig. 8.

serve to sink it. A heavy rope, usually made of old netting, tightly twisted and bound round with strong twine, is lashed along the bosom of the net. Thus *mounted*, the engine is lowered into the sea, being *trailed* or *trawled* along the bottom by means of a rope attached to the boat's mast, and communicating with each end of the *beam* by a *bridle*. The *bosom* touches the ground, and the *upper blade* and *beam* floats over it; the *bosom's* rope disturbs the fish at the bottom; they are, however, stopped from escaping by striking against the *upper blade*, which extends over the *bosom*, so they swim down the *trawl* to the *hose*; but this is tied up, so they next attempt to return towards the mouth of the net; but in their way they fall into the pockets, which only open inwards towards the *hose*, and thus are secured. A *day-net* is used for catching larks from 14th September to 14th November; after that, until 25th February, the *trammel*. The reason of this is, that during the latter division of the season the weather usually is cloudy, and the *doring-glass* of the *day-net* cannot act. The structure of this net is very simple, and is represented in fig. 9. The thread

Fig. 9.

should be very fine, as also that used for the *trammels*; the meshes three-quarters of an inch from knot to knot; two pieces of *oblong* netting, measuring three fathoms by one, are extended to their full width, by being lashed to light staves of the required length, one at each end. These two leaves are to be laid on the ground exactly opposite each other, so accurately that when they are drawn over, the two margins *m, m* shall touch each other. Each leaf is to be staked down with pegs at the lower corners, at G, G, G, G. Lines *Bg* and *Bg* are to be stretched from the top of the stakes B, B, and fastened firmly to the ground by the pegs *g, g*. Other lines are to be stretched from the head of the stakes *b* and *b*, in the direction of *bC, bC*, and fixed to the ground by a peg C and C. Other lines F and F are to proceed from the head of each stake *b, b*, and are to be joined at H to the *main line*, which draws the leaves over; F, F should each be at least a fathom long. In the centre D is to be placed the *doring-glass*, whence proceeds a line E. The fowler retires to his ambuscade, and with his left hand he plays the *doring-glass* with the line E, and holds the *main line* H in his right; when the birds are seen playing around the glass, and within reach of the net, he pulls the leaves over with a quick jerk, and thus secures them. The *doring-glass* is thus made:—Take a piece of wood (AC, fig. 10) nine inches long and one and a half thick, cut out in the shape of an arch, and the edges at the top bevelled off so as to make it a six-sided figure. This bow is to be painted red, and covered with pieces of looking-glass along the sides and at each end; a wooden peg B, six inches long and three-fourths of an inch in circumference

Fig. 10.

Reticulation.

Retimo.

a little pointed at the end, with a hole at I, through which the line E (fig. 9) is threaded, must be fixed to the under surface of the arch, at the centre. Take another piece of wood six inches thick and one foot long (fig. 11), sharpened at the end in order to fix it in the ground; cut out a mortise in it two inches high, and one inch and three-fourths deep; bore a hole at N and O, large enough to receive the peg B (fig. 10). This device is made to act by winding up the string round the peg several turns, and then pulling it; then letting it wind itself up again, and then jerking it again; thus making the glass revolve briskly, as children do their toy wind-mills.

Fig. 11.

The various nets above described may be modified, altered, and combined, as occasion requires. It would be endless to enter into these minutiae, or to give a catalogue of the different nets used, with the technical name for each in different parts of the kingdom. We shall therefore conclude with a few *general observations*. 1. In all cases use twine as fine as circumstances will permit, and make the meshes as large as is consistent with the object in view; for the nets will be thereby more easily dried, lighter, and more efficient. 2. In filling the needle *double*, draw the twine from separate balls. 3. Take great care to dry the nets thoroughly, and hang them up away from walls, where rats and mice cannot get at them. 4. Mend them immediately. 5. Keep them well tanned, or immersed in *Kyan's Patent* as often as may be necessary; but never use tar and oil. This mixture has been proved to be inefficient as a preservative, and to be so offensive to the fish as to drive many away from the nets thus prepared, and to impart an unpleasant flavour to those that are caught in them. 6. If you wish to *dye* the nets green, russet, yellow, &c., for fowling or other purposes, send them to the nearest dyer or tanner, as the cheapest and best mode of treatment. Machines have at various times been invented for making nets. Jacquard, the inventor of the celebrated weaving apparatus which gives his name to the loom to which it is attached, was the first to construct a machine of this kind. He was prompted thereto by seeing an advertisement offering a reward for such a machine, and although he had not previously directed his attention to mechanical invention, he succeeded without much difficulty. Napoleon I., who was attentive to every display of talent likely to be turned to account in his contest with Great Britain, no sooner heard of the invention than he sent to Lyons and ordered Jacquard to be brought to Paris. This was done; and no sooner did the emperor see him than he exclaimed, as coarsely as profanely, "Are you the man that pretends to do what God Almighty cannot—tie a knot in a stretched string?" The net-making machine did not produce much fruit, but it served to develop the latent mechanical genius of the inventor. Other machines intended to effect a similar object have not met with much favour. Nor need we be surprised at this when it is considered that the demand for nets is for the most part met by those who use them, and fishermen and others have a good deal of leisure which cannot be better employed than in mending and making the machines on which they depend for subsistence. Gardeners, school-boys, and even females also amuse themselves profitably in netting; and a very easy exertion is sufficient to supply the quantity of net required. The meshes of the healds of looms, through which the warp passes, are sometimes made by a net-making machine. Lace-net is manufactured by machinery, as described in the article

LACE.
(C. B.) (C. T.)
RETIMO, or RETTIMO (anc. *Ruthymna*), a sea-port town of the island of Crete, on the N. coast, 38 miles W. of Candia. It has a citadel, a harbour (now so choked up as

to be very shallow), and a considerable trade in oil and soap. Pop. 6000.

Retz.

RETZ, JEAN FRANÇOIS PAUL DE GONDI, *Cardinal de*, a celebrated politician, was born of a rich and powerful house at Montmirail in 1614. In accordance with the wish of his father, he entered the church; but his youthful conduct was glaringly inconsistent with his profession. A passion for the daring and the romantic was his ruling motive. He gloried in fighting duels and carrying on love-intrigues. He was especially ambitious to become the leader of a popular faction, and the declared foe of tyrants. It is true that he frequently settled down to his studies; but at those times his attention was chiefly engrossed with the deeds of Catiline, and other great conspirators of antiquity. So fierce, indeed, did his revolutionary enthusiasm become, that he entered into a plot for assassinating Cardinal Richelieu. "It would have been an act," said he, in justification of himself, "which ancient Rome would have admired." Gondi, however, soon saw occasion to lay aside his wayward impetuosity, and to adopt a new mode of gratifying his romantic love of effect. The fiery politician now subsided into the meek-eyed churchman. He became addicted to religious duties and religious company. He advocated the doctrines of the church, and on one occasion was the means of converting a Protestant gentleman. His appointment in 1643 to be coadjutor to his uncle the Archbishop of Paris only increased his ecclesiastical zeal. He began to be a great stickler for the forms and observances of the church. All the mere outward duties of his office were performed with astonishing thoroughness. He even plunged himself into debt, in order that he might practise Christian liberality to the utmost. It was not until the civil broils of the Fronde had broken out in 1648 that he ceased to play the part of a religious devotee. Gondi was then induced by his love of political excitement, and his desire of becoming a popular leader, to mingle in the contest. Dexterous, eloquent, generous-hearted, and free from all mercenary motives, he soon became the most influential man among the Frondeurs. There was no one who was more successful in advancing the interests of the party, and at the same time in providing for his own safety. As long as the rebellion appeared successful, he managed to moderate and check the wayward and discordant impulses of his accomplices. When it was clear that it would effect nothing, he came out of it, in 1651, with a cardinal's hat. It was not long, however, before De Retz was subjected to a severe course of punishment on account of his political career. In 1652 Cardinal Mazarin threw him into prison. He escaped indeed in 1654; but the persecuting influence of his adversary followed him wherever he went. For seven years he wandered about the Continent beset with poverty and danger. Not until Mazarin had died, in 1661, was he able to effect his reconciliation with Louis XIV., and to return to France. The remainder of De Retz's career presents a striking contrast with the former part. Misfortune had now stripped away all his romantic love of effect, and had allowed the other qualities of his fine disposition to come into play. No longer fond of public activity, he resigned the see of Paris, and devoted himself to the peaceful pursuits of private life. His first act was to sell his estates. With one part of the proceeds he paid his immense debts, and with the other part he assisted his friends and relieved the poor. He then sat down to write his *Mémoires*, and to recall and criticise with impartial spirit the noisy and eventful scenes of his bygone days. Thus did he live an honourable, benevolent, and eloquent old man, till death closed his career on the 24th of August 1679. The *Mémoires* of De Retz are characterized by Voltaire as "written with an air of grandeur, an impetuosity of genius, and an inequality which are the image of his conduct." The best edition is that in 4 vols. 8vo, Am-

Reuchlin. sterdam, 1731. An English translation, by P. Davall, was published in 4 vols. 12mo, London, 1774.

REUCHLIN, or CAPNIO (a Greek equivalent), JOHANN, a scholar illustrious for his services in the revival of letters and liberation of thought in the fifteenth and following centuries, was born at Pforzheim 28th December 1455. It is stated, on the authority of an ancient chronicle, that his father George was a common messenger; at all events, he was of the humblest ranks of life. A younger brother, Dionysius, who afterwards rose to some distinction, and a sister, Elizabeth, completed the family. At school his sweetness of voice and natural talent for music were remarked, and he was placed in the choir of the chapel of the margrave, who, pleased with his talents, his progress in grammar, and the sweetness of his disposition, sent him to Paris in 1473 with his son Frederic, afterwards bishop of Utrecht. Here he perfected himself in Latin, and applied himself to Greek under Hermonymus of Sparta, the second teacher of Greek in Paris, Georgius Tiphemas having been the first. He also profited by the instructions of Johannes à Lapide, Tardivus, and Robert Gaguin, supporting himself partly by copying parts of Greek authors for richer students. At the end of 1474 he went to Basle, where, while teaching Latin and Greek, he improved his knowledge of the latter under Andronicus Contoblacas. Here also, or previously at Paris, he came under the influence of Wessel (*Lux Mundi*) who encouraged him in his Greek studies and initiated him in the elements of Hebrew. At Basle he had access to the valuable Greek manuscripts brought thither at the time of the council by the Cardinal de Ragusio. His simpler method of instruction, and the freer exercise of thought and speculation with which he familiarized his pupils in expounding the original text of Aristotle, attracted many, and also brought him much envy and enmity. Having remained at Basle four years, he went to Orleans to study the civil and canon law, and while there taught Latin and Greek with great reputation. He continued these studies in 1480 at Poitiers, and in 1481, having received there the highest degree in law, he returned to his native country, fixing his residence at Tübingen, a town recommended to him by the society of learned men connected with the new university founded by Eberhard *im Bart* ("the Bearded"), and by the well-known enlightenment of that prince. Here he practised as advocate with great prosperity, and married. Having been taken into Eberhard's confidence, he accompanied him to Rome in 1482, where the regard and esteem he conciliated by his learning, his purer Latin, and eloquence, confirmed him in Eberhard's favour, who till his death, 24th February 1496, continued to employ him in diplomatic business. More important for Reuchlin himself was his intercourse at Rome and Florence, during his two visits to Italy in 1482 and 1489 with Chalcondylas, Marsilius Ficinus, Politianus, and Pico di Mirandola, for from that intercourse his studies and speculations received an entirely new direction.

On his return to Germany in 1482 he remained at Stuttgart with Eberhard. In 1484 he was nominated assessor of the supreme court, and during the life of Eberhard was engaged in many missions which need not be enumerated here. Being employed at the court of the Emperor Frederick III., he so gained the esteem of that potentate as to be ennobled, and presented by him with a valuable Hebrew MS. of the Bible, now preserved in the library of Durlach. From the emperor's Jewish physician, Jakob Jehiel Loanz, he received further instruction in Hebrew. On the death of Eberhard a revolution took place in the court of Würtemberg. Eberhard the younger, who succeeded, dismissed his predecessor's counsellors, and a previous adviser of his own, Holzinger, who had been, at Reuchlin's suggestion, thrown into prison, was restored to favour. Reuchlin, who

had everything to fear, fled, first to Worms, and then, on the invitation of his warm friend Johann von Dalberg, Bishop of Worms, to Heidelberg. Here his life seems to have been one of pleasant labour in the most congenial society. He did much for the university: arranged and increased its library, wrote a *Manual of Civil Law* for the Bursa or law college, made various translations of Greek books, wrote an epitome of universal history, and procured the erection in 1498 of a Greek chair, to which his brother Dionysius was called from Tübingen. He also wrote a comedy entitled *Sergius*, aimed at Holzinger, and satirizing the dissolute lives of the monks, but was dissuaded by Dalberg from having it acted, and substituted another, *Scenica Progymnasmata*, an imitation of *Patelin*. Another visit to Rome in 1498, in the cause of Philip the elector-palatine, who had been excommunicated by the Pope for the detention of some monastic revenues, he turned to advantage by availing himself of the instructions in Hebrew of Obadiah Sphorno, a learned Jew, who exacted, however, a heavy price for his lessons. His meeting with Argyropulus, then teaching Greek at Rome, and astonishing him by expounding a passage of Thucydides, is well known. He returned, having succeeded in his mission, and brought with him many manuscripts and printed works. While in Rome a counter revolution had taken place in Würtemberg; Eberhard had been deposed, and a council appointed till the majority of Ulric. Reuchlin, therefore, returned to Stuttgart, resolved to devote himself entirely to learning. He was again, however, pressed into public business, being appointed (1501) judge of the Swabian League (renewed in 1500), an office he filled for eleven years. With the duties of this office, and the toils of his profession, he contrived to unite laborious study, the fruit of which appeared in 1506 in his great work *Linguae Hebraicae Rudimenta*, a work important for that time not only in a philological point of view, but as rendering possible that free study of the original Scriptures on which the religious emancipation that was shortly to follow could only have securely founded itself. Besides this work, he put forth many Latin translations of small Greek works; and by his extensive correspondence exerted great influence in directing the studies of earnest scholars. It is clear also, from an inspection of this correspondence, that, while by no means a profound or systematic thinker, or advocate of formulas, his sound discernment of the true end, and proper methods of education, contributed powerfully to its elevation in Germany, and its liberation from an oppressive pedantry. It may be remarked here also, that these letters are of the highest value for the literary history of a period which, in regard to the subsequent revolution, may be called the period of causes, and which has been too exclusively studied from fixed dogmatic stand-points. While to Luther, as chief, is due the positive Reformation, by proclaiming a return to Scripture and free thought as the basis of a purer Christianity, yet previous to Luther's outburst there had long been going on round Reuchlin, as a centre, a quiet movement of free intelligence which could not fail, in spite of its merely negative and unreligious character, to come at last into open collision with the dominant ignorance and superstition. Only an occasion was wanting; and this occurred in 1509. Johann Pfefferkorn, a converted (or rather apostate) Jew of Cologne, and protégé of the Dominicans there, who had already distinguished himself by writing against his former faith, procured, with the assistance of the monks, an order from the Emperor Maximilian that the Jews should give up to be burnt all their books hostile to Christianity. Finding the execution of this order very difficult, partly on account of the restriction stated, partly from the rarity of zeal like his own, he petitioned for a new mandate, removing the restriction, and ordering the destruction of all Jewish books but the Bible. The

Reuchlin.

Reuchlin. emperor named a commission to consider the question, of whom Reuchlin was one. He accordingly forwarded his *Opinion* to the Elector of Mentz in August 1510. In this able document, which, with the one presently to be mentioned, will be found in Von der Hardt's *Histor. Liter. Reformationis*, the reasoning is almost entirely based on the mischievous results to christian learning and zeal of the proposed destruction, but there are indications of a sound doctrine concerning liberty of conscience, and true perception of the real nature of religion, which cannot be propagated by violence, that must have appeared very strange to the monks of Cologne. The *Opinion* getting abroad by treachery, Pfefferkorn published a virulent personal reply, entitled *Handspiegel* ("Mirror"), to which Reuchlin returned an *Augenspiegel* ("Spectacles"). Frightened at the violent measures the Cologne were taking against this book and the author, he was yet unable to concede the essence of his position, and accordingly the *Klare Verstantnis in Teutsch*, which he published in 1512 by way of sedative, was as offensive as his two previous tracts. His enemies selected Judaizing propositions from it, and published them. Reuchlin replied in a *Defensio contra Calumniatores Colonienses*. In 1513, the emperor having imposed silence on both parties, the Dominicans called forth Hochstraten, a Dutch inquisitor, who took charge of the affair as a heresy. We need not follow his proceedings, remarkable only for irregularity and failure. On appeal to Rome in 1516, the Pope (Leo X.) appointed a commission, which by a majority decided in favour of Reuchlin; but Hochstraten, by means, it was said, of bribery, procured from the Pope a *mandatum de supersedendo* putting off a settlement of the business at his pleasure. In the meantime the literary warfare raged in Germany: a confederacy of Reuchlinists, the most active of whom were Ulrich von Hutten and Willibald Pirckheimer, was formed; and on the other side, Ortunus Gratius, a Dominican and professor at Cologne, published, under Pfefferkorn's name, many libels against Reuchlin, while Hochstraten sought, among other modes of attack, to find heresy in Reuchlin's cabalistic writings. All these libels and epigrams have perished, but the *Epistolæ Obscurorum Virorum*, which astounded the combatants on both sides in 1516 (part second, 1517), remains an unsurpassed masterpiece of the cruellest and most truthful satire. The laughers, and they are the most of the world, were now all on one side, and the laugh could only be redoubled by the *Lamentationes Obscurorum Virorum*, which appeared in 1517 as an answer. To answer a laugh is, in any way, a hopeless thing, but to answer it by a lamentation is a desperate thing. In the war between Franz von Sickingen and Duke Ulrich of Wurtemberg, Reuchlin was obliged to leave Stuttgart, and retired, by the invitation of Duke William of Bavaria, to Ingoldstadt, November 1519. While there, his process was settled by the intervention of Sickingen, who sent an embassy to Cologne, threatening that, unless they paid Reuchlin his expenses, and made him compensation and apology, he would make war on the city. The conditions were, after some attempts at compromise, complied with. At Ingoldstadt he received a pension of 200 gold crowns annually from the duke; and lectured on Hebrew and Greek to a great concourse of students. He returned in 1521 to Stuttgart, on account of the plague appearing in Ingoldstadt, and was immediately invited by the university of Tubingen to teach there. He removed thither, and began his labours, but falling ill, returned to Stuttgart, where he died of jaundice, December 21, 1521. Erasmus, a cold and timid friend when Reuchlin was alive, wrote the dialogue entitled *Apotheosis Capnionis*, and introduced him into heaven.

Reuchlin was in his age regarded with singular admiration and affection by scholars of all countries; and Germany still regards him, as well she may, as the patriarch of her

erudition. Of his cabalistic philosophy a full account, and a rather one-sided one, will be found in the fourth volume of Brucker's *Histor. Crit. Philos.* He derived it partly from Mirandola, and partly from his study of the forged cabalistic books of the Jews. A full list of Reuchlin's works will be found in the supplement to Jocher's *Lexikon*. His library has been mostly incorporated in that of Carlsruhe. A portrait of him exists in the university of Glessen. (W. H. C.)

REUS, a town of Spain, Catalonia, in the province and 9 miles W. of Tarragona, stands at the foot of a chain of hills in a fertile plain, about 4 miles from the sea. It is a bustling, flourishing town, forming a striking contrast to the decaying grandeur of its neighbour city Tarragona. One portion, however, is as old as 1151; the rest was built about six centuries later. This modern town is regularly laid out, with broad streets and squares; cold in winter, and exposed during the summer to the rays of a glaring sun, from which the more ancient town is sheltered by its narrow and crooked lanes. The houses are generally well built: many of the public squares are adorned with fountains; and the largest of them, which is the chief place of resort for the people, is surrounded with wide colonnades. The large Tuscan town-house, with its spacious halls enriched with paintings and statues, is one of the chief buildings; the plain Gothic parish church lifts high its hexagonal tower; the college and schools are accommodated in the splendid buildings of a former Franciscan convent; a Carmelite convent has likewise given place to the hospital, to which belongs the theatre of the town; and there is also an orphan asylum, and a large new prison. Silk, cotton, and linen are the chief produce of the industry of Reus; dyeing, bleaching, tanning, distilling, and other operations are also carried on. The prosperity of the citizens is attested by their many fine villas scattered round the town. The trade too is very considerable; the weekly markets determine the prices of various articles throughout Spain. There is a railway from this place to Tarragona; and a canal connecting Reus with the port of Salou, which is very exposed, and safe only in summer. By this port the produce of the country and of the manufactures in the town is exported abroad; while in return there is much importation of flour, timber, hides, live-stock, &c. During the peninsular war Reus tamely submitted to the French in 1808, and in consequence was much impoverished by their exactions under Macdonald. Pop. 28,034.

REUSS, the name of two principalities in Germany, among the smallest of the states of the German Confederation, but which form the remains of a country that was anciently much more extensive. The country, bounded by Bohemia, Bavaria, and Thuringia, seemed to the German kings to be from its position and natural character, so defended as not to require the protection of a margrave, but was to be governed by officers of the crown; and accordingly divided into five bailiwicks (*Vogteien*), viz.,—Weida, Plauen, Gera, Greiz, and Hof. Of these, Weida and Gera belonged in the twelfth century to Henry the Rich, a prince probably descended from the ancient families of Luxemburg, Schwartzburg, and Gleisberg, who afterwards obtained possession of the other three bailiwicks. His four sons, dividing the land among them, founded the lines of Plauen, Greiz, Weida, and Gera. The three last became extinct in 1236, 1532, and 1550 respectively; from the first are descended the present princes of Reuss, from Henry II., second son of Henry the Rich. The family did not at this time bear the name of Reuss, but this title was introduced in the next generation. The son of Henry II. left two sons, who were surnamed, from the nationality of their mothers, Henry the Bohemian and Henry the Russian (*Russe* or *Reusse*). From the Bohemian descended a line of lords (*Herren*) of Plauen, which became extinct in 1572; their possessions being lost in various

Reuss. ways to the surrounding states, till the last of them was sold in 1569 by the last of the family to the Elector of Saxony. But the other family, with the name of Reuss and a part of the original territory, was more durable. It was, and still is, a peculiarity in this family, that all its members, in honour, it is said, of the Emperor Henry IV., who first elevated the original Henry the Rich, bear the name of Henry, and were distinguished at first by surnames, or by the titles of Elder, Middle, and Younger; afterwards by numbers, with the necessary provision that after reaching C. in the elder branch, and at the end of each century in the younger, they begin again with I. The two lines at present existing are derived from two of the sons of Henry the Peaceful, who died in 1535. Both branches were raised in 1673 to the rank of counts of the empire and to that of princes,—the elder or Reuss-Greiz line in 1778, and the younger or Reuss-Schleiz in 1806. The younger line was subdivided in 1666 into the branches of Gera, Schleiz, and Lobenstein; the first became extinct in 1802, and its possessions were governed in common by the others, till in 1848 the last prince of Reuss-Lobenstein, Henry LXXII, abdicated in favour of the Prince of Reuss-Schleiz; so that there now exist only the two principalities. The country consists of two parts, separated from each other,—the more northerly bounded N. by Prussia, S. by part of Saxe Weimar, E. and W. by the two parts of Saxe Altenburg; the more southerly lying between Saxony and Bavaria on the S., and parts of Schwartzburg, Prussia, and Saxe Weimar on the N. The former and the western portion of the latter form the principality of Reuss-Schleiz, the remainder that of Reuss-Greiz. The area and population of the two countries are:—

	Sq. miles.	Pop. (1855.)
Reuss-Greiz.....	144	35,159
Reuss-Schleiz.....	447	80,203
Total.....	591	115,362

A considerable part of the principalities is mountainous, being occupied by branches of the Erzgebirge and Frankensteinwald. This part of the country is for the most part well wooded; but there are also valleys and small plains. The principal rivers that water the country are the Saale and its affluent the Elster, both flowing in general from S. to N. Though in some parts light and sandy, yet the greater part of the soil is fertile, and yields in both principalities the ordinary productions of Germany. The climate is temperate. Among the mineral riches of the land are to be numbered iron, salt, building-stone, slate, potters' and porcelain clay, and alum. Farming is largely carried on. Corn is produced in Reuss-Greiz below, and in Reuss-Schleiz above the demands of the inhabitants. In both there are also raised potatoes, pulse, flax, and hops. Of the former, the most important produce is timber, especially pines and firs; the latter derives much of its wealth from the rearing of cattle; and contained in 1849, 2074 horses, 29,677 horned cattle, 33,419 sheep, 5046 goats, and 14,963 pigs. The principal manufactures in both are those of woollen and cotton fabrics; the larger principality manufactures also tobacco, beer, brandy, pottery, and other articles. There are exported manufactured articles, iron, timber, butter, and cattle. In both principalities the government is in the hands of a prince, limited in each by a separate diet. The highest law tribunal is the upper court of appeal at Jena, beneath which there are courts at Greiz, Gera, and other places. The princes and the great majority of their subjects are of the Lutheran religion. Education is well provided for by numerous elementary schools, two Latin schools, a gymnasium, and three normal seminaries; the university of Jena is considered the national one. The military force of Reuss-Greiz is 609, that of Reuss-Schleiz 260; total, 869. The annual public revenue of the former amounts to about L.8400, of the latter L.38,000; the expenditure L.37,000.

REUTLINGEN, a town of Württemberg, capital of the Reutlingen circle of Schwarzwald, at the foot of the Swabian Alp, on the Echatz, the water of which flows through the town, 6 miles E. of Tübingen, and 20 S. of Stuttgart. It is a stately old town, walled and moated, in an exquisitely beautiful position, with the long line of steep hills, the dark, dense pine forests, green meadows, and rich, waving fields of corn, all combining to enhance the picturesqueness of the scenery, a fine view of which is obtained from the lofty isolated hill Achalm, close at hand. The Protestant church of St Mary is considered the finest ecclesiastical building in Württemberg; it is of elegant proportions, and contains some curious ancient ornaments. A large, handsome town-hall, and a Franciscan convent, now occupied by government offices, are among the other edifices of the town. There are here too several schools and a public library; manufactures of woollen cloth, cotton, leather, hats, &c.; and a considerable trade in these, as well as in the produce of the country. Reutlingen formerly belonged to the counts of Achalm, the ruins of whose castle, on the hill of that name, are still to be seen. Pop. (1855) 12,367.

REVEL, or **REVAL** (Esth. *Talline*, Russ. *Kolyvan*), a seaport of European Russia, capital of the government of Esthonia, on a bay of the same name, on the S. coast of the Gulf of Finland, 200 miles W.S.W. of St Petersburg. It consists of an upper and a lower town; the former, on a steep rocky eminence, contains the cathedral and castle, and is encircled with walls and towers. This is the best quarter, and in it are most of the houses of the nobility. In the lower town the streets are narrow and irregular, but many of the houses are well built of brick. Revel has also two suburbs. The cathedral is an edifice of an incongruous architectural character, with a lofty and elegant tower, and contains many interesting tombs. In the same part of the town stands the hall of the nobility, where the Diets of Esthonia used to assemble. The church of St Olai, recently rebuilt, after a conflagration in 1820, contains many relics, including the archives and library, of a much higher antiquity, the original having been built in 1329. It is the cathedral church of the lower town, and is in the early Gothic style, with beautiful lancet windows. St Nicholas is another large church, with a massive square tower, and contains many antique monuments and works of art. The oldest church in the town, however, is the Esthonian, which is mentioned as early as 1284. A modernized town-house, the admiralty, and several guild-halls for the various corporations, the chief being that of the Black Heads (*Schwarzen Haupter*), a once famous club of merchants for the defence of the city, are among the public buildings. For education there is a gymnasium, founded by Gustavus Adolphus, and various other schools; also public libraries, a theatre, hospital, &c. The imperial palace of Catherine, founded by Peter the Great, and bequeathed by him to Revel, is a favourite resort of the townsfolk during the summer. The manufactures of the place include leather, cotton goods, hosiery, hats, earthenware, mirrors, &c. The trade, though still considerable, both by sea and land, has within the last twenty years greatly fallen off, being transferred to St Petersburg and Riga, or even to Pernau and Libau. Revel was once one of the most flourishing of the Hanse towns. It has large and excellent harbours for merchantmen and men-of-war, the latter occupied by a division of the Russian Baltic fleet. On the island Nargen, at the entrance of the harbour, stands a lighthouse. Revel was founded about 1218 by Valdemar II. of Denmark; and afterwards, along with Esthonia, it belonged to Sweden, Brandenburg, and the Teutonic knights, and to Peter the Great. Pop. (1855) 27,905.

REVEL, a town of France, department of Haute-Garonne, 29 miles E.S.E. of Toulouse, on a hill overlooking a beautiful and fertile country. It has manufactures of linen and cotton cloth, hosiery, hats, leather, tiles, &c. Pop. 5960.

Revelation, Book of. REVELATION, BOOK OF. The following topics in relation to this book demand examination:—1. The person by whom it was written. 2. Its canonical authority, genuineness, and authenticity. 3. The time and place at which it was written. 4. Its unity. 5. The class of writings to which it belongs. 6. The object for which it was originally written. 7. Its contents.

1. *The Person by whom it was Written.*—The author styles himself John, but not an apostle (i. 4, 9; xxii. 8). Hence some have attributed the book to another John, usually designated the presbyter. The chief argument for believing that there was another John besides the apostle exists in a passage from Papias of Hierapolis, preserved in Eusebius (*Hist. Eccles.* iii. 39). In this fragment several of the apostles, among whom is John, are mentioned; while immediately after, the presbyter John is specified along with Aristion. In addition to Papias, Dionysius of Alexandria (Euseb. *Hist. Eccles.* vii. 25), Eusebius himself (*Hist. Eccles.* iii. 39), and Jerome (*Catal. Scriptor. Ecclesiast.*), allude to the presbyter. We must therefore believe with Lücke, Bleek, Credner, Neander, Hitzig, and indeed all the ablest critics who have had occasion to speak of this point, that there were two Johns,—one the apostle, the other the presbyter. It has been much debated which of the two wrote the book before us. On the Continent the prevailing current of opinion, if not in favour of the presbyter, is at least against the apostle. In England the latter is still regarded as the writer, more perhaps by a kind of traditional belief than as the result of enlightened examination.

The arguments against assigning the authorship to the apostle John are the following:—The apocalyptic writer calls himself John, while the evangelist never does so. The language of the book is entirely different from that of the fourth Gospel and the three Epistles of John the apostle. It is characterized by strong Hebraisms and ruggednesses, by negligences of expression and grammatical inaccuracies; while it exhibits the absence of pure Greek words and of the apostle's favourite expressions. The style is besides unlike that which appears in the Gospel and Epistles. It is alleged likewise that the doctrinal aspect of the Apocalypse is different from that of the apostle's acknowledged writings. Such are the arguments advanced by De Wette. They are chiefly based on the investigations of Ewald and Lücke. It will be observed, however, that they are all *internal*, and do no more than prepare the way for proving that John the presbyter was the writer. Let us glance at the *external* evidence adduced for the same purpose.

In the third century Dionysius of Alexandria ascribed the book to John the presbyter, not to John the apostle (Euseb. *Hist. Eccles.* vii. 32). The testimony of this writer has been so often and so much insisted on that it is unnecessary to give it here. However, there is no *direct* evidence in favour of the opinion that John the presbyter wrote the Apocalypse. Many internal considerations have been adduced to show that *John the apostle was not* the author; but no *direct* argument has been advanced to prove that John the presbyter was the writer. Others think that a disciple of John undertook to write on a subject which he had received from the apostle; and Hitzig has lately written a treatise to prove that the writer is John Mark, the same from whom the second Gospel proceeded. His arguments are mainly based on parallelisms of language and construction (*Ueber Johannes Marcus und seine Schriften, oder welcher Johannes hat die Offenbarung verfasst?* Zurich, 8vo, 1843.)

Justin Martyr is the earliest writer who attributes it to John the apostle (*Dial. cum Tryph.*) Tertullian, Clement of Alexandria, and Origen ascribe it to the apostle. The internal evidence in favour of John the apostle, urged by De Wette, Lücke, Ewald, and Credner, at considerable length, bears mainly upon the language of the writing,

characterized as it is by strong Hebraisms, deficient as it also is in purely Greek idioms, and contrary as are some of the Gospel statements to those of the Epistles. Some have attempted to turn aside the force of those arguments by resorting to the hypothesis, that the book was originally written in Hebrew, and then translated into Greek. This, however, is contradicted by the most decisive internal evidence, and is in itself highly improbable. One circumstance to be taken into account is, that the nature of the gospel is widely different from that of the Apocalypse. The latter is a prophetic book—a poetical composition—while the former is a simple record in prose of the discourses of Jesus in the days of his flesh. It is apparent too, that John in the Apocalypse imitates the manner of Ezekiel and Daniel. The New Testament prophet conforms to the diction and symbolic features of the former seers. “If the question should be urged, why John chose these models? the obvious answer is, that he conformed to the taste of the times in which he lived. The numerous apocryphal works of an apocalyptic nature which were composed nearly at the same time with the Apocalypse, such as the book of Enoch, the ascension of Isaiah, the Testament of the twelve patriarchs, many of the sibylline oracles, the fourth book of Ezra, the Pastor of Hermas, and many others which are lost,—all testify to the taste and feelings of the times when, or near which, the Apocalypse was written. If this method of writing was more grateful to the time in which John lived, it is a good reason for his preferring it. (Stuart, in the *Bibliotheca Sacra*, pp. 353, 354.) In view of the whole question, we are disposed to abide by the ancient opinion, that John the apostle wrote the Apocalypse. Ecclesiastical tradition clearly favours this view; while the internal grounds so carefully drawn out and earnestly urged by recent German critics, do not appear sufficiently strong to overturn it. When such grounds are soberly examined, after being divested of all the extravagance with which they are associated; when the nature of the subjects discussed is seen to be such as the fourth Gospel does not present; an impartial critic will probably rest in the opinion, that both writings proceeded from the same author.

The entire question of authorship, so much debated in Germany, is more curious than profitable. The book may not have been written by an apostle, and yet be equal in authority to any acknowledged production of an apostle.

2. *Its Canonical Authority, Authenticity, and Genuineness.*—We shall first of all consider the external testimonies adverse to its canonicity.

The Alogi or Antimontanists in the second century, ascribed all John's writings, including the Apocalypse, to Cerinthus, as Epiphanius relates. It is obvious that no weight can be attached to these assertions. Caius of Rome, from opposition to Montanism, ventured to make the same statement, as we learn from Eusebius (*Hist. Eccles.* iii. 28). The 85th of the “Apostolic Canons,” which are supposed to belong to the fourth century, does not mention the Apocalypse among the apostolic writings. In the “Constitutions” also, which probably originated in Syria and the adjacent regions, there is no notice of the book. Chrysostom, Theodoret, Theodore of Mopsuestia, the theologians of Nisibis, Junilius, Cyril, Gregory of Nazianzen, Euthalius, all probably agreed in rejecting the Apocalypse. At the time of the Reformation the controversy respecting the Apocalypse was revived. Erasmus speaks suspiciously concerning it, while Luther expresses himself very vehemently against it. With Semler a new opposition to it began. That distinguished critic was unfavourable to its authenticity. He was followed by Oeder, Merkel, Michaëlis, Heinrichs, Bretschneider, Ewald, De Wette, Schott, Bleek, Lücke, Neander, Credner, E. Reuss, Hitzig, Tinius, &c. It should, however, be distinctly observed that most of these recent critics go no farther than to deny that John

Revelation, the apostle was the writer; which may certainly be done without imputing its indirectly apostolic authority. They do not exclude it from the canon as a divinely-inspired writing; although in attacking its direct apostolicity, some may imagine that they ruin its canonical credit.

We shall now allude to the evidence in favour of its canonicity. The earliest witness for it is Papias, as we learn from Andreas and Arethas of Cappadocia, in their preface to Commentaries on the Apocalypse. (Havernick's *Lucubrationis Criticæ ad Apoc. spectantes*, Regiom. 1842, 8vo, No. 1, p. 4, sq.) Melito, Bishop of Sardis, one of the seven apocalyptic churches, wrote a work exclusively on this book. Jerome, in his catalogue of illustrious men, explicitly distinguishes two works, one respecting the devil, the other relative to the Apocalypse. Theophilus, Bishop of Antioch (Euseb. iv. 24), in his book against Hermogenes, drew many proofs and arguments from the Revelation; so also Apollonius of Ephesus, according to the same ecclesiastical historian (v. 18). The testimony of Irenæus is most important, because he was in early life acquainted with Polycarp, who was John's disciple, and because he resided in Asia Minor, where John himself abode during the latter part of his life. In one place he says, "It was seen no long time ago, but almost in our age, towards the end of Domitian's reign;" while he frequently quotes it elsewhere as the *Revelation of John, the disciple of the Lord*. To these may be added the testimony of the martyrs at Lyons, of Nepos (Euseb. vii. 23), Methodius of Tyre, Didymus of Alexandria, Cyprian, Lactantius, Augustine, Athanasius, Basil the Great, Epiphanius of Cyprus, Jerome, Ephrem the Syrian, Rufinus the presbyter, Isidore of Pelusium, Hilary of Poictou, Cyril of Alexandria, Arethas and Andreas of Cappadocia, the Synod of Hippo (A.D. 393, canon 36), the Synod of Toledo (A.D. 633), the third council of Carthage (A.D. 397), Victorin of Pettaw in Pannonia, Dionysius the Areopagite, Sulpicius Severus, Joh. Damascenus, Œcumenius, Amphilochius, Novatus and his followers, the Manichees, the Donatists, the Arians, the latter Arnobius, Rhaban Maurus, Isidore of Spain, Commodian, and others. At the period of the Reformation Flacius strenuously upheld the authority of the Apocalypse, and since his day able defenders of it have not been wanting. Twells, C. F. Schmid, J. F. Reuss, Knittel, Storr, Luderwald, Hartwig, Kleuker, Herder, Donker Curtius, Hanlein, Bertholdt, Eichhorn, Hug, Feilmoser, Kolthoff, Olshausen, J. P. Lange (Tholuck's *Lit. Anzeig.* 1838), Dannemann, Havernick (*Evangel. Kirchenzeit.* 1834, and *Lucub. Criticæ*), Guerike, Schnitzer (*Allgem. Literaturzeit.* 1841), Zeller (*Deutsche Jahrb.* 1841), and others. Thus the general tenor of the external evidence is clearly in favour of the canonical authority, while internal circumstances amply confirm it. The style, language, and manner of the book, cannot be mistaken. In dignity and sublimity it is equal to any of the New Testament writings, if not superior to them all. The variety and force of the images impress the mind of every reader with conceptions of a divine origin. Surely no uninspired man could have written in such a strain.

3. *The Time and Place at which it was Written.*—In ascertaining these points there is considerable difficulty. The prevalent opinion is, that the book was written A.D. 96 or 97, at Patmos or Ephesus, after Domitian's death,—i.e., under Nerva. So Mill, Le Clerc, Basnage, Lardner, Woodhouse, and others suppose. In view of all the circumstances of the case, which cannot here be fully entered into, we are inclined to believe that it was written at Patmos in the time of Nero, A.D. 67 or 68, a date fixed upon long ago by Sir Isaac Newton.

4. *Unity of the Book.*—A few writers have thought that the Apocalypse was written at different times by the same author, as Grotius, Hammond, and Bleek; or by different authors, as Vogel. Such dismemberment is now aban-

doned. Even De Wette allows that no reasonable doubts can be entertained of its unity.

5. *The Class of Writings to which it belongs.*—Pareus seems to have been the first who started the idea of its being a dramatic poem. The same opinion was also expressed by Hartwig. But the genius of Eichhorn wrought out the suggestion into a theory pervaded by great symmetry and beauty. Hence the opinion that it forms a regular dramatic poem is associated with his name alone. As this theory, however, is now abandoned by all expositors, it needs no refutation.

6. *The Object for which it was originally Written.*—The books of the New Testament, like those of the Old, were designed to promote the instruction of God's people in all ages. They were adapted to teach, exhort, and reprove all mankind. They do not belong to the class of ephemeral writings that have long since fulfilled the purpose for which they were originally composed. Their object was not merely a local or partial one. So of the Apocalypse. It is suited to all. "Blessed is he that readeth, and they that hear the words of this prophecy." But this general characteristic is perfectly consistent with the fact, that it arose out of specific circumstances, and was primarily meant to subserve a definite end. When first written, it was destined to suit the peculiar circumstances of the early Christians.

7. *Its Contents.*—The body of the work is contained in chaps. iv.—xxii. 6, and is almost entirely a series of symbolic representations. To this is prefixed a prologue (i.—iv.) A brief epilogue is subjoined (xxii. 6–21). After the prologue or introduction, which is peculiarly fitted to admonish and console amid suffering, we come to the body of the work itself, commencing with the fourth chapter. This may be appropriately divided into three parts,—(1.) iv.—xi.; (2.) xii.—xix.; (3.) xx.—xxii. 5.

By far the greater number of works on the Apocalypse are of no value, the authors having failed to perceive the primary purpose of the apostle. We shall only mention a few. The best book on the literature of the Apocalypse is that of Lücke, published in 1832. It is both copious and excellent. In addition to it may be mentioned the *Introductions* of Michaelis, Haenlein, Eichhorn, Bertholdt, Hug, Feilmoser, De Wette, Credner, Schott, Guerike; and the *Introduction* of Samuel Davidson, London, 1848. Bleek's *Beiträge zur Kritik der Offenbarung Johannis* (in the *Zeitschrift* of Schleiermacher, De Wette, and Lücke, ii. 252 sq.); Kleuker, *Ueber Ursprung und Zweck der Offenbar. Johannis*; Steudel, *Ueber die richtige Auffassung der Apocalypse* (in Bengel's *N. Archim.* iv. 2); the treatises of Kolthoff, Lange, and Dannemann, already referred to; Knittel's *Beiträge zur Kritik über Johannis Offenbarung*; Vogel's *Commentatio de Apoc. Johannis*, pt. i. vii.; Neander's *History of the Planting and Training of the Christian Church*; Olshausen's *Proof of the Genuineness of the Writings of the New Testament* (translated by Fosdick, Andover, 1838); Lardner's *Credibility of the Gospel History*, vols. i. and iii. 4to edition; Havernick, in the *Evangelische Kirchenzeitung*, and *Lucubrationes*, already quoted.

The principal commentaries on the Apocalypse are those of Pareus, Grotius, Vitranga, Eichhorn, Heinrichs, Scholz, Ewald, Tinus, Bossuet, Alcasar, Hentenius, Salmeron, Herrenschneider, Hagen, and Hengstenberg's *Revelations of St John Expounded for those who Search the Scriptures*. Of English works, Lowman's *Commentary* has been highly esteemed, though his scheme is wrong. Mede's *Clavis*, and the *Commentary* attached to it, have had great influence on subsequent writers; Faber's *Sacred Calendar of Prophecy* is able and ingenious, but radically wrong; Sir Isaac Newton's *Observations on the Apocalypse*, and Bishop Newton's *Remarks*, are generally incorrect. Cunningham has written various treatises illustrative of the

Revelat on,
Book of.

Apocalypse, but his lucubrations are dark and doubtful. Woodhouse's *Commentary* is prevaed by commendable diligence and sobriety, though he has greatly deviated from the right mode of interpretation. We specially recommend Hammond and Lee (*Six Sermons on the Study of the Holy Scriptures*, London, 1830, 8vo). English apocalyptic literature has of late years greatly accumulated; and we can only mention the following:—*Horæ Apocalypticæ*, London, 1848; Moses Stuart, *A Commentary on the Apocalypse*, third edition, London, 1854, a voluminous and exhaustive treatise; Albert Barnes, *A Commentary on the Book of Revelation*, 1851, published both in America and London; Desprez, *The Apocalypse fulfilled in the Consummation of the Mosac Economy, and the coming of the Son of Man, an Answer to the "Apocalyptic Sketches" and "The End,"* by Dr Cumming, second edition, London, 1855.

REVELATION. See THEOLOGY.

REVEREND, a title of respect given to ecclesiastics. In England, bishops are *right reverend*, and archbishops *most reverend*. In France, before the Revolution, the bishops, archbishops, and abbots were all alike *most reverend*. In Scotland, the clergy individually are *reverend*, a synod is *very reverend*, and the General Assembly is *venerable*.

REVERSION, in the law of England, has two significations; the one of which is, an estate left, which continues during a particular state in being; and the other is the returning of the land, after the particular estate is ended; and it is further said to be an interest in lands when the possession of it fails, or where the estate, which was for a time parted with, returns to the granters or their heirs. But according to the usual definition of a reversion, it is the residue of an estate left in the granter, after a particular estate granted away ceases, continuing in the granter of such an estate.

The difference between a remainder and a reversion consists in this, that the remainder may belong to any man except the granter; whereas the reversion returns to him who conveyed the lands.

REVERSION, in annuities. See ANNUITIES.

REVIEW, the name ordinarily employed by literary usage to designate that species of periodical publication containing a collection of critical essays. The first review, properly so called, was the *Journal des Savans*, commenced at Paris on the 30th May 1665. The most noted modern French journals of this class are the *Revue Française* and *Des Deux Mondes*. The French "revues" are conducted on a different plan from the English. With the former the form of a *review* is not preserved, tales, poetry, &c., being admitted indiscriminately; and the name of the contributor must be attached. The first publication of this kind in England was the *Monthly Review*, begun in 1749. However, it was reserved for the *Edinburgh Review*, commenced in 1802, and the *Quarterly*, in 1809, to inaugurate a new era in criticism. Since the beginning almost of the present century the review has been the favourite organ of all sects and parties for disseminating their peculiar views on religion, politics, or literature. For the most part, the leading reviews appear quarterly, although the tendency seems to be increasing of having monthly, or in some cases weekly reviews. A good specimen of the latter species of journal is to be had in the *Saturday Review* (1856). The prevailing period, however, of publishing the review is quarterly; and all the principal organs of that class published at the present day, viz., the *Edinburgh* (1802), *Quarterly* (1809), *North American* (1815), *Westminster* (1824), *Southern American* (1828), *Calcutta* (1843), *North British* (1844), *British Quarterly* (1844), *National* (1855), *Bentley's* (1859), and a number of others, are of this description. In England the management of a review is placed in the hands of an editor, the publisher being alone responsible in

all monetary affairs connected with the publication. The Revolution articles are for the most part anonymous; and the reviewer confines himself, although not very strictly, to the production of a review or general essay on some work or works, placed at the head of his article, which he either notices in detail, or which serve to indicate the general character of his subject. The pay of writers in reviews is various, depending on the means of the review, and likewise on the rules adopted by the editor. In Germany reviews have taken even a deeper root than in England; and the *Göttinger Gelehrte Anzeige* which is the oldest publication of the kind, still maintains a high character.

REVOLUTION of 1688. See BRITAIN.

REVOLVER. See GUN-MAKING.

REWA CAUNTA, a division of India, Guzerat, in the presidency of Bombay, lying between N. Lat. 21. 23. and 23. 33., E. Long. 73. 3. and 74. 18, and bounded on the N. by Myhee Caunta, E. by the small states of Banswarra, Dohud, Jabooah, Allee, and Akrauna, S. by the British collectorate of Candeish and the district of Wusravee, and W. by the collectorates of Kaira and Sura. It comprises the following states:—

Name.	Square Miles.	Population.	Revenue.	Annual amount of Subsidy, Tribute, or other Payment.	Military Resources.
			L.	L.	
Barreah	870	64,380	5765	1200	211
Loonawarra ...	500	37,000	4000	1920	150
Oodepoor	1059	78,366	7400	1050	438
Rajpeepla.....	1650	122,100	20,397	6000	384
Soauth	425	31,450	2000	700	140
Mewasi chiefs.	375	27,750	...	6761	..
Total...	4879	361,046	...	17,631	.

Barreah is tributary to the British, whose protection it enjoys; Loonawarra is protected by the British, and tributary to Scindia and the Guicowar; Soauth is protected by the British, and tributary to Scindia; the others in like manner tributary to the Guicowar.

REWAH, or BAGHELKUND, an independent state of India, bounded on the N. by the British districts of Allahabad and Mirzapore, E. by the latter and the native state Korea, S. by the British districts of Sohagepoor and Saugor and Nerbudda, and W. by that of Saugor and Nerbudda and by Bundelcund, lying between N. Lat. 23. 20. and 25. 10., E. Long. 80. 40. and 82. 52; length, from E. to W., about 140 miles; breadth, 120; area, 9827 square miles. A considerable part of the country, its western and north-western portion, is occupied with hills, rising in three successive terraces from the level of the plain. The first of these averages from 500 to 530 feet high, the second from 900 to 1200 feet, and the third attains a still greater height. Sandstone, limestone, schist, and quartz are the principal geological constituents of the hills. Most of Rewah belongs to the valley of the Son, an affluent of the Ganges, which flows through the country in an irregular course generally towards the N. and E., receiving from the left the Mahanuddee, and various smaller streams from both sides. The north-western portion is very well cultivated, and produces large crops; wheat, barley, and peas being chiefly raised. Cattle and sheep are kept in large numbers. Much of the surface, however, is unfit for cultivation, and a great part is occupied by wood, which furnishes timber to the British districts in the valley of the Ganges. The inhabitants are Rajpoots, and of the Brahminical religion; they are governed by a rajah, who is bound by treaty, since 1813, to receive a permanent British agent. His revenue is estimated at L.200,000, and his military force exceeds 8000 men. Pop. 1,200,000.

Reynolds. The capital is a town of the same name, on the Beher, an affluent of the Tons, which flows into the Ganges, 131 miles S.W. of Allahabad. The town is inclosed by two lofty and thick walls, flanked with towers, and the large ruinous palace of the rajah by a third of similar construction. It is a mean and poor-looking place, with a population of 7000.

REYNOLDS, SIR JOSHUA, a celebrated English painter, was born at Plympton, a small town in Devonshire, on the 16th July 1723. His father was minister of the parish, and also master of the grammar school; and being a man of learning and philanthropy, he was beloved and respected by all to whom he was known. Such a man, it will naturally be supposed, was assiduous in the cultivation of the minds of his children, amongst whom his son Joshua shone conspicuous, by displaying at a very early period a superiority of genius and the rudiments of a correct taste. At an early age he grew passionately fond of painting, and, by the perusal of Richardson's theory of that art, was determined to make it his profession through life. At his own earnest request, therefore, he was removed to London; and about the year 1742 became a pupil to Hudson, a Devonshire man, who was the most eminent painter of his day, although very little real ability was implied in that distinction, and was preceptor to several who afterwards excelled in the art. One of the first advices which he gave to Reynolds was to copy carefully Guercino's drawings. This was done with such skill that many of the copies are said to be now preserved in the cabinets of the curious as the originals of that very great master.

About the year 1749 Reynolds went to Italy under the auspices and in the company of Lord (then Commodore) Keppel, who was appointed to the command of the British squadron in the Mediterranean. In this garden of the world, this magical seat of the arts, he failed not to visit the schools of the great masters, to study the productions of different ages, and to contemplate with unwearied attention the various beauties which are characteristic of each. His labour here, as has been observed of another painter, was "the labour of love, not the task of the hireling;" and how much he profited by it is known to all Europe.

Having remained about two years in Italy, and studied the language as well as the arts of the country with great success, he returned to England, improved by travel and refined by education. On the road to London from the port where he landed, he accidentally found in the inn where he lodged Johnson's *Life of Savage*; and was so taken with the charms of composition and the masterly delineation of character displayed in that performance, that, having begun to read it whilst leaning with his arm on the chimney-piece, he continued in that attitude, insensible of pain, till he was hardly able to raise his hand to his head. The admiration of the work naturally led him to seek the acquaintance of its author, who continued one of his most sincere admirers and warmest friends till 1784, when they were separated by death.

The first thing that distinguished him after his return

to his native country was a full-length portrait of Commodore Keppel, which in the polite circles was spoken of in terms of the highest encomium, and testified to what a degree of eminence he had arrived in his profession. This was followed by a portrait of Lord Edgumbe and a few others, which at once introduced him to the first business in portrait-painting; and that branch of the art he cultivated with such success as will for ever establish his fame with all descriptions of refined society. Having painted some of the first-rate beauties of the age, the polite world flocked to see the graces and the charms of his pencil; and he soon became the most fashionable painter, not only in England, but in all Europe. He has indeed preserved the resemblance of so many illustrious characters that we feel the less regret for his having left behind him so few historical paintings; though what he has done in that way shows him to have been qualified to excel in both departments.¹ The only landscape, perhaps, which he ever painted, except those beautiful and chaste ones which compose the backgrounds of many of his portraits, is a "View on the Thames from Richmond," which in 1784 was exhibited by the Society for Promoting Painting and Design in Liverpool.

In 1764 Reynolds had the merit of being the first promoter of that club which, having long existed without a name, became at last distinguished by the appellation of the *Literary Club*. Upon the foundation of the Royal Academy of Painting, Sculpture, and Architecture, he was appointed president; and his acknowledged excellence in his profession made the appointment acceptable to all the lovers of art. To add to the dignity of this new institution, his Majesty conferred on the president the honour of knighthood; and Sir Joshua delivered his first discourse at the opening of the academy in the beginning of the month of January 1769. The merit of that discourse has been universally admitted among painters; and it contains some directions respecting the proper mode of prosecuting their studies, to which every student of every art would do well to pay attention. "I would chiefly recommend," says he, "that an implicit obedience to the rules of art, as established by the practice of the great masters, should be exacted from the young students. That those models which have passed through the approbation of ages should be considered by them as perfect and infallible guides; as subjects for their imitation, not their criticism. I am confident that this is the only efficacious method of making a progress in the arts; and that he who sets out with doubting will find life finished before he becomes master of the rudiments. For it may be laid down as a maxim, that he who begins by presuming on his own sense has ended his studies as soon as he has commenced them. Every opportunity, therefore, should be taken to discountenance that false and vulgar opinion, that rules are the fetters of genius. They are fetters only to men of no genius; as that armour which upon the strong becomes an ornament and a defence, upon the weak and misshapen turns into a load, and cripples the body which it was made to protect."

Reynolds.

¹ As the lovers of painting may wish to have a catalogue of this great master's historical pieces, we subjoin the following:—Hope nursing Love; Venus chastising Cupid for having learned to cast accounts; Count Ugolino in the Dungeon; the Calling of Samuel; Ariadne; a Captain of Banditti; a Beggar Boy; a Lady in the character of St Agnes; Thais; Dionysius the Areopagite; an infant Jupiter; Master Crewe in the character of Henry VIII.; the Death of Dido; a Child asleep; Cupid sleeping; Covent Garden Cupid; Cupid in the Clouds; Cupids painting; a Boy laughing; Master Herbert in the character of Bacchus; Hebe; Miss Meyer in the character of Hebe; Madonna, a head; the Blackguard Mercury; a little Boy (Samuel) praying; an old Man reading; Love loosing the zone of Beauty; the Children in the Wood; Cleopatra dissolving the Pearl; Garrick in the character of Kiteley; Garrick between Tragedy and Comedy; Mrs Abingdon in the character of Comedy; a Child surrounded by Guardian Angels; Miss Beauclerc in the character of Spenser's Una; Resignation; the Duchess of Manchester in the character of Diana; Lady Blake in the character of Juno; Mrs Sheridan in the character of St Cecilia; Edwin, from Beattie's *Minstrel*; the Nativity, Four Cardinal Virtues, and Faith, Hope, and Charity, for the window of New College Chapel, Oxford; the Studious Boy; a Bacchante; a daughter of Lord W. Gordon as an Angel; the Holy Family; the Cottagers, from Thomson; the Vestal; the Careful Shepherdess; a Gipsy telling Fortunes; the infant Hercules strangling the Serpent; the Mouse-trap Girl; Venus; Cornelia and her Children; the Bird; Melancholy; Mrs Siddons in Tragedy; Head of Lear; Mrs Talmash in the character of Miranda, with Prospero and Caliban; Robin Goodfellow Death of Cardinal Beaufort; Macbeth, with the Cauldron of the Witches.

Reynolds.

Each succeeding year, on the distribution of the prizes, Sir Joshua delivered to the students a discourse of equal merit with this; and perhaps we do not hazard too much when we say that, from the whole collected, the lover of belles lettres and the fine arts will acquire juster notions of what is meant by taste in general, and better rules for acquiring a correct taste, than from multitudes of those volumes which have been professedly written on the subject.

In the autumn of 1785 he went to Brussels, where he expended about L.1000 on the purchase of paintings, which, having been taken from the different monasteries and religious houses in Flanders and Germany, were then exposed to sale by the command of the Emperor Joseph. Gainsborough and he had engaged to paint each other's portraits; and the canvas for both being actually stretched, Sir Joshua gave one sitting to his distinguished rival; but, to the regret of every admirer of the art, the unexpected death of the latter prevented all further progress.

In 1790 he was anxiously desirous to procure the vacant professorship of perspective in the academy for Bononi, an Italian architect; but that artist not having been yet elected an associate, was of course no academician, and it became necessary to raise him to these situations in order to qualify him for being a professor. Gulpin being his competitor for the associateship, the numbers on the ballot proved equal, when the president by his casting-vote decided the election in favour of his friend, who was thereby advanced so far towards the professorship. Soon after this, an academic seat being vacant, Sir Joshua exerted all his influence to obtain it for Bononi; but finding himself outvoted by a majority of two to one, he quitted the chair with great dissatisfaction, and next day sent to the secretary of the academy a formal resignation of the office, which for twenty-one years he had filled with honour to himself and his country. His indignation, however, subsiding, he suffered himself to be prevailed upon to return to the chair, which within a year and a half he was again desirous to quit for a better reason.

Finding a disease of languor, occasioned by an enlargement of the liver, to which he had for some time been subject, increase upon him, and daily expecting the total loss of sight, he wrote a letter to the academy, intimating his intention to resign the office of president on account of bodily infirmities, which disabled him from executing the duties of it to his own satisfaction. The academicians received this intelligence with the respectful concern due to the talents and virtues of their president; and either then did enter, or designed to enter, into a resolution, honourable to all parties, namely, that a deputation from the whole body of the academy should wait upon him, and inform him of their wish that the authority and privileges of the office of president might be his during his life; declaring their willingness to permit the performance of any of its duties which might be irksome to him by a deputy.

From this period Sir Joshua never painted more. The last effort of his pencil was the portrait of Charles James Fox, which was executed in his best style, and shows that his fancy, his imagination, and his other great powers in the art which he professed, remained unabated to the end of his life. When the last touches were given to this picture,

"The hand of Reynolds fell, to rise no more."

On Thursday the 23d February 1792 the world was deprived of this amiable man and excellent artist, at the age of sixty-eight years; a man than whom no one, according to Johnson, had passed through life with more observation of men and manners. The following character of him is said to be the production of Mr Burke:—

"Sir Joshua Reynolds was, on very many accounts, one of the most memorable men of his time; he was the first Englishman who added the praise of the elegant arts to the

other glories of his country. In taste, in grace, in facility, in happy invention, and in the richness and harmony of colouring, he was equal to the great masters of the renowned ages. In portrait he went beyond them; for he communicated to that description of the art in which English artists are the most engaged, a variety, a fancy, and a dignity, derived from the higher branches, which even those who professed them in a superior manner did not always preserve when they delineated individual nature. His portraits remind the spectator of the invention of history and the amenity of landscape. In painting portraits he appears not to be raised upon that platform, but to descend to it from a higher sphere. His paintings illustrate his lessons, and his lessons seem to be derived from his paintings. He possessed the theory as perfectly as the practice of his art. To be such a painter, he was a profound and penetrating philosopher. In full happiness of foreign and domestic fame, admired by the expert in art and by the learned in science, courted by the great, caressed by sovereign powers, and celebrated by distinguished poets, his native humility, modesty, and candour never forsook him, even on surprise or provocation; nor was the least degree of arrogance or assumption visible to the scrutinizing eye in any part of his conduct or discourse. His talents of every kind, powerful from nature, and not meanly cultivated in letters, his social virtues in all the relations and all the habitudes of life, rendered him the centre of a very great and unparalleled variety of agreeable societies, which will be dissipated by his death. He had too much merit not to excite some jealousy, too much innocence to provoke any enmity. The loss of no man of his time can be felt with more sincere, general, and unmixed sorrow." (See ARTS, *Fine*, and PAINTING.)

Memoirs of Sir Joshua Reynolds have been written by James Northcote and by Beechey, and very recently by William Cotton. Cotton has likewise published catalogues illustrative of Sir Joshua's art (1859).

RHABDOLOGY. (See NAPIER, *John*.)

RHADAMANTHUS (*Ῥαδάμανθος*), a son of Zeus and Europa according to Homer (*Il.* xiv., 322), and according to others a son of Hephestus (*Paus.* viii. 53 § 2). Having fled from his brother to Boeotia, he there married Alcmena, and led a life of such signal integrity and justice that at his death he was appointed one of the three judges of the infernal regions, and had his abode in Elysium.

RHÆTIA, a country of ancient Europe, was bounded on the N. by Vindelicæ, on the E. by Noricum, on the S. by Italy, and on the W. by the district of the Helvetii. It was a most romantic territory. The Alpes Rhæticae, and Mons Adula traversed it in all directions. Between the offshoots of these hills lay many a well-watered pastoral valley. The pastures were covered with flocks; and at intervals there appeared those vineyards out of which the favourite wine of Augustus was produced. The Rhætians, when they were invaded by the Romans, shortly before the Christian era, were chiefly composed of fierce Celtic freebooters. They struggled savagely with the legions for their mountain homes. The very women shot arrows; and when their missiles failed, threw their children in the face of their foes. Yet the Rhætians lost every vestige of independence. Their armies were completely routed in 15 B.C. by Drusus and Tiberius. Their language not long afterwards was displaced by the Latin. Their country continued to be a Roman province, at one time by itself, at another time in conjunction with Vindelicæ (to which it then extended its name). Nor after the fall of the empire did they recover their liberty. The Ostrogoths kept them in subjection until the Boioarii finally settled down in their country. The chief town in Rhætia was Tridentum (*Trent*).

Rhabdology
||
Rhætia.

Rhamnus
||
Rhegium.

RHAMNUS, an ancient town of Greece, was situated on the eastern coast of Attica, about 60 stadia N. from Marathon, and received its name from the shrub *rhamnus*, which grew in its neighbourhood. The fame of the city was chiefly derived from its temple of Nemesis. That edifice, according to the commonly received opinion, was built shortly after the victory of Marathon, and was adorned by Phidias with a colossal image of the patron goddess. The fragments of its columns and great statue are still seen beyond the wall of the ruined city, on the same platform, with the remains of another and smaller temple.

RHAPSODIST (*ῥαψωδός*, from *ῥάπτω*, *I string together*, and *ὥδή*, *a song*), is strictly one who strings songs together, and is usually applied to a class of persons who earned their living by reciting the poems of Homer. These poems came accordingly to be divided into certain lengths called *rhapsodies*,—that is, lays, fyttes, or cantos. (Liddell and Scott's *Lexicon*.) In modern usage, the rhapsodist is one who composes rhapsodies, or collections of thoughts into a new whole, without any natural connection or necessary dependence.

RHAZES, or **RAZES**, the Latinized name of Mohammed Ibn-Zakaria Abu-Beker Al-Razi, a most distinguished Arabian physician, who was born at Rai, in the province of Khorassan, about 852. His professional studies were not begun in early life. At the age of thirty he was only known as a dexterous performer on the guitar. It was not until he was beyond forty that he vigorously applied himself to the study of medicine at Bagdad. Rhazes then took a high place in his profession. The directorship of the famous hospital of Bagdad was conferred upon him. Neighbouring princes frequently applied for his advice. In particular, Almansour of Khorassan (in honour of whom he called one of his books *Ketáb Almansóuri*), liberally patronized him. His fame increased until he was reckoned the most learned physician of his day. He had mastered philosophy, alchemy, and astronomy. He had travelled far in quest of knowledge. He had also written above 200 treatises on professional subjects. A characteristic anecdote is told regarding the close of the life of Rhazes. Happening from some cause not sufficiently ascertained to be struck with blindness, he called in a surgeon to operate upon his eyes. The operation was just about to be made, when he asked the surgeon how many optic membranes there were. The surgeon could not answer. Upon this he would not allow him to touch his eyes, and remained blind till his death in 932. The following is a list of those works of Rhazes which have been translated into Latin:—*Liber de Secretis qui Aphorismorum appellatur*, Bologna, 1489; *Havi seu Continens*, in 2 vols. folio, Venice, 1509; *Libri Decem ad Almansorem*, folio, Venice, 1510; and *De Variolis et Morbilis, Arabice et Latine; cura et impensis Johannis Channing*, in 8vo, London, 1766. An English translation of this last work, made directly from the original Arabic, was published by Dr Greenhill, 8vo, London, 1847.

RHEGIUM (the modern *Reggio*), an ancient Greek city in Italy, was situated on the Sicilian straits, at the end of the Brutian peninsula. The town seems to have been in existence before the historical period, but its importance did not begin till the eighth century B.C. A colony from Chalcis, along with some exiles from Messenia, then settled in it, and commenced to form themselves gradually into a regular corporation. The government was placed in the hands of a council consisting of 1000 Messenians. The laws of Charondas of Catana were afterwards adopted as a constitution. In course of time the state was so consolidated as to be able to extend its sovereignty over the small towns in the neighbourhood. The prosperity of Rhegium, however, received a still greater stimulus after Anaxilas had established a tyranny in 494 B.C. Its foreign policy

Rheims.

became more decidedly aggressive. Zancle, on the opposite side of the strait was subdued, and under the name of Messana, was made a colony of the Messenians. The promontory of Scyllæum was fortified and turned into a naval station. The command of the straits was thus effectually maintained against the Tyrrhenian pirates. At the same time, the state enjoyed great internal order. The tyrant Anaxilas and the regent Micythus ruled in succession with great justice and moderation. It was not until the accession of the two sons of Anaxilas that the people became turbulent, and, rising in rebellion, overthrew the monarchy in 461 B.C. In 399 B.C. a long course of severe disaster began to befall Rhegium. Dionysius the Syracusan tyrant, enraged at its opposition to his schemes of conquest, doomed it to destruction. Every attempt to avert his vengeance, both by force and negotiation, was ultimately unsuccessful. In 387 B.C. he starved it into capitulation, massacred or sold the inhabitants, and levelled the houses with the dust. It is true that the city was shortly afterwards rebuilt, and regained, in course of time, a great part of its prosperity; but it was only to meet with another calamity. In 280 B.C., alarmed at the successes of Pyrrhus, King of Epirus, the citizens applied to the Romans for assistance. The request was granted, and 4000 Campanians were sent to garrison the town. These ruthless soldiers had not been long there before they rose against the inhabitants. They slew all the men, fortified themselves within the town, and were not reduced till ten years afterwards. During the subsequent period of ancient history, Rhegium, though still retaining its importance, continued subject to foreign dominion. As long as Rome was supreme in Italy, it acknowledged the sway of that city. After the dismemberment of the empire it passed through the hands of various conquerors, until it was taken and made a part of the kingdom of the Two Sicilies by Robert Guiscard in 1060. (See *REGGIO*.)

RHEIMS, or **REIMS**, a town of France, the largest, but not the capital of the department of Marne, stands in a plain amid vine-covered hills, on the Vesle, an affluent of the Aisne, 27 miles N.N.W. of Chalons, and 82 E.N.E. of Paris. It is encircled by a moat and ramparts, which have been planted with trees, and now form an agreeable public walk. The four ancient gates once bore the names of Mars, Venus, Ceres, and Bacchus; the first of them consists of a triumphal arch, whose graceful Corinthian columns contrast beautifully with the Gothic structures about it. A modern gate was opened beside it in the sixteenth century, and another was opened in honour of Louis XVI. in 1774. Though one of the oldest towns in France, the streets of Rheims do not in general present that picturesque appearance which often accompanies antiquity; some of them indeed are quite modern. The houses, seldom more than one or two storeys high, have a very dull and uniform aspect. The great glory of the place is the cathedral of the metropolitan see of France, which is considered by many to be the most magnificent church north of the Alps. It was built by Robert de Coucy (1212–41), but its towers are still unfinished, so as to detract from the perfection of the building. Nothing is more striking about the exterior than the unity and harmony of the whole, notwithstanding the many statues and other ornaments with which it is profusely embellished. The interior has much resemblance to that of Westminster Abbey, only it is bolder and simpler, much more so than the exterior; but the exceedingly brilliant painted glass in the windows throws over the whole “a dim religious light,” which supplies the place of more elaborate decorations. There are few monuments in the cathedral now; the most remarkable being a white marble sarcophagus of Jovinus, an ancient prefect of Rheims. The abbey of St Remi is older than the cathedral, having been built partly in the eleventh and

Rhenanus
||
Rhetoric.

partly in the twelfth century; partly too at later epochs, so that it is a curious medley of different styles. Much injury, now quite repaired, was done to it at the Revolution: archbishops and nobles were torn up from its vaults; and the *Sainte Ampoule*, the heaven-descended oil-flask for anointing the regal heads of France, was publicly broken in pieces, though a fragment of it mysteriously re-appeared at the coronation of Charles X. The town-hall is a handsome modern building, with a statue of Louis XIII. in front. A theatre, college, public library, and various schools are among the establishments of the town. The chief manufacture is that of woollen cloth, which has its centre here; hosiery, soap, candles, biscuits, and gingerbread are also produced; and dyeing, brewing, tanning, &c., are carried on. The principal article of trade is the wine of Champagne; but besides this, agricultural produce, woollen and cotton stuffs are exported here. Besides being the see of an archbishop, Rheims contains courts of law and a chamber of commerce. Previous to the invasion of Julius Cæsar the town was called *Durocortorum*, and was the capital of the Remi, a native tribe, from whom the modern name is derived. Under the Romans it was a place of much importance, the capital of Belgica Secunda, adorned with fine buildings, and probably the seat of a school of learning. Christianity is said to have been introduced and the cathedral founded in the fourth century. Soon after, the barbarian hordes invaded Gaul; but in 496 Clovis and his Franks were converted and baptized here. The cathedral of Rheims has been the scene of the consecration of most of the French monarchs, from Philip Augustus in 1179, till that of Charles X. Of these ceremonies, probably none had been more interesting than that which took place in 1429, when Charles VII. was crowned here; Joan of Arc, bearing her sacred banner, kneeling with tears of joy before the sovereign whom she had restored to his throne. The town was taken by the Russians in 1814, but before they had been in possession many hours Napoleon came down upon them, and gained here one of his last successes before victory deserted his standards. Rheims is celebrated as the birthplace of the statesman Colbert and the Abbé Pluche. Pop. (1856) 48,350.

RHENANUS, BEATUS, one of the revivers of learning in Germany, was the son of a wealthy butcher, and was born at Schlettstadt in 1485. From his youth upwards, the greatest facilities for acquiring knowledge were enjoyed

by him. He studied at Paris under the ablest teachers of which that city could boast. He then resided for some time at Basel, in the learned society of Erasmus and Gelenus. His succession to his father's fortune in 1520 increased his advantages. Retiring to his native city, he was enabled to devote the remainder of his life exclusively to the quiet and congenial pursuits of his study. The result of this propitious career was, that Rhenanus at his death, in 1547, left a long list of publications. Among these was the *Edtio Princeps* of Paterculus, the manuscript of which he discovered in the monastery of Murbach. There was also an original work entitled *Rerum Germanicarum Libri Tres*, folio, Basel, 1531, a work which has been often reprinted.

RHENUS. See RHINE.

RHETICUS, or RHÆTICUS, the surname which George Joachim derived, from having been a native of that part of the Tyrol which was anciently the territory of the Rhæti. This eminent scholar was born at Feldkirch in 1514, and was appointed professor of elementary mathematics at Wittenberg in 1537. His first appearance before the public was in the character of an enthusiastic convert to the newly-broached opinions of Copernicus. No sooner had he adopted these opinions than, resigning his chair, he repaired to Frauenberg to sit at the feet of their great promulgator. All his energy was forthwith devoted to the new system. His aid was given in completing it. His pen was employed in advocating it. His power of persuasion was used to get its founder to lay it before the public. Nor did he desist when it was ready for the press. Receiving the manuscript he superintended the printing, and placed the new work in the hand of the expiring author. Rheticus now commenced his great treatise, *Opus Palatinum de Triangulis*. It exacted from him the most arduous and the most patient labour. He continued to work at it, while he occupied his old chair at Wittenberg, while he taught mathematics at Leipsic, and while he travelled over different parts of the Continent. His toil was not yet over when he died in Hungary in 1576. The *Opus Palatinum* of Rheticus was published by Otho in 1596, and was found to contain the most extensive trigonometrical table that had hitherto appeared. This table was rendered still more complete by Pitiscus, the learned philologist, and published under the name of *Thesaurus Mathematicus*, folio, 1613.

Rhetoric.

RHETORIC.

Opinions as
to the
function of
rhetoric.

1. The name Rhetoric is exceedingly flexible. In any just sense it signifies the theory of certain processes of communication, all of which have language for their instrument.

When, again, ideas expressible by language are thought worthy of being made communicable both widely and permanently, the expression of them is recorded, and constitutes what may rightly be called a literary work. The literary character is stamped on such works, more or less deeply, by the fact of their being recorded; whatever may have been the occasion that gave them birth, and whether it may have been to the eye or to the ear that they were in the first instance addressed. Works so preserved, besides being the only specimens accessible to patient criticism, are reasonably presumed to be the best in their several kinds: from the study of them, accordingly, are deduced systematic expositions of the laws governing the processes which they severally exemplify; and such laws are justly held to be binding on all similar processes, even though they should assert no claim to a place in the literary record.

The processes, therefore, which rhetoric aims at analysing,

may correctly be described as being Literary. Ought we, however, to place under that name the whole theory of literature—the theory of each and all of its departments? If we ought not, between what points is the line of extension to be drawn? The name, like every other that has long been in use, suggests to every one certain precise ideas; and to these, for the avoidance of confusion, due deference must be paid in any technical meaning that is to be attached to it.

When Rhetoric is said to be the Theory of Eloquence, a description is offered which will be accepted pretty generally. It leads us promptly to a limitation of the sphere. If rhetoric, theorizing admittedly processes which are literary, exhausts the theory of literature, poetry must be held to be a species of eloquence. But the word eloquence can hardly by any one be taken in a meaning so wide as to make this inclusion natural, or to save a theory which adopts it from the risk of frequent misapprehension. Popularly, indeed, we limit the name eloquence to an extent which cannot altogether be prevented from embarrassing the expression of rhetorical doctrines: we are apt

Introduction.

to confine it exclusively to compositions of an imaginative or passionate cast. Within this narrowed meaning there lies yet another, which restricts the name to spoken oratory; but this is not likely to mislead.

As to the function of rhetoric, accordingly, there have been entertained diverse opinions. The principal of these are four. These, however, as it will immediately appear, are practically brought, by inevitable short-comings in the analysis, within shorter distances from each other than they may at first seem to hold.

In the first place, the name has been applied to the whole theory of literature or literary composition. This view guides the outline of Campbell's *Philosophy of Rhetoric*; although the treatise, left incomplete, hardly carries the analysis of poetry further than a few hints on style. It has already been said that this widest meaning of the term is inadmissible.

Secondly, the name has been applied to the theory of all kinds of literature that are not poetical. Eloquence being that which is theorized in rhetoric, the whole realm of literature is in this view distributed into two provinces, designable severally as eloquence and poetry.—It is well to say, thus early, that this is a just distribution; but only with the proviso, that the two provinces be distinguished from each other according to a sound principle. Literary works should be disposed, primarily, according to their several purposes; since it is the character of the purpose that determines for a process its paramount laws. Eloquence and poetry, then, are separated by difference of purpose. All literary processes having a certain purpose are correctly comprehended under the name Poetry. To cover all literary processes having any other purpose, no apter name can be found than Eloquence; and the theorizing of all such processes is embraced correspondingly under the name of Rhetoric.—A caution, however, must here be given, and pressed very emphatically. The twofold distribution of the whole range of literature becomes utterly deceptive, and precludes the construction of a true theory for either department, when it is founded, as it has been oftener than not, on a principle which ought to yield only lower steps of classification,—namely, that of form. This is the principle which is adopted when all literary compositions are divided into two kinds, poetry and prose; for the name poetry is thus intended to cover all literary works written in verse, and to exclude all others. The just contrary of prose is not poetry, but verse: the two are merely names for forms into which words may be thrown. Whether a work is poetical or not is a question to be determined by its purpose: it may not be poetical, although its language is metrically modulated; it may be poetical, although its language, not having such modulation, must be called prose. It is the fact, no doubt, that prose is not, and cannot rightly be, adopted as the form of poetry which is designed to be either pure or elevated; and accordingly, the language is metrical in all works which are currently and universally called poetical. So, contrariwise, in all nations and times that yield works calling for criticism, prose is taken as the form of every composition aiming distinctively at any effect not poetical. Therefore the identification of prose with eloquence does, in effect, submit to examination all works which are the fruit of processes justly falling within the description of eloquence. But it takes in likewise certain kinds of works which ought to be excluded; and the mistake which lies at the root must vitiate all the broadest of the inferences to be afterwards drawn. This mistake does, in fact, pervade almost all attempts that have been made, in this country at least, to construct rhetorical systems which should be valid for all works not poetical. The design has been announced as being the laying down of rules for prose composition; and, the execution of the design rising seldom if ever above questions of

VOL. XIX.

Introduction.

style, the consequences of the vicious assumption have not been brought into a prominence sufficient to secure their detection.

In each of the two views which are still to be described, rhetoric is treated as being specifically and properly the theory of oratory. The forms and conditions of public speaking are assumed as data; and kinds of eloquence which are addressed exclusively to the eye of the reader, either receive no notice or supply but occasional illustration. Within those limits this question is raised:—whether all oratorical processes should be analysed, or only certain of them? Oratory may aim at no further effect than the generation of belief or explicit knowledge, through assertion or argumentation, or both; and the processes available for this purpose may be said to constitute argumentative eloquence. Again, those processes being pre-supposed, oratory may aim at the generation of desire and volition, through the representation of emotive images; and the relative processes may be said to constitute persuasive eloquence. Many rhetoricians have treated processes of both kinds: many have restricted their field to the latter of the two.

Thirdly, then, there have been included, under the name of rhetoric, the theories both of argumentative and of persuasive oratory, no immediate cognizance being taken of any other processes. This was the view prevalent, with perhaps no exception, among the Greek and Roman theorists; it was especially adopted both by Aristotle and by Cicero. It is thus that the function of rhetoric is determined by Archbishop Whately.

Fourthly, rhetoric has been considered as being exclusively the theory of persuasive oratory. Argumentative eloquence has been excluded from its sphere, on one or another of several grounds. It has been alleged by some that the process is exhaustively theorized in logic; that there is no difference, practically appreciable, between a process of inference and the communication of that process. By others the communication of inference has been made the object of a special theory, to which, in scholastic times, there was sometimes given the name of Dialectics in one of its several meanings. Yet, again, it has been maintained, and oftenest on the north of the Tweed, that we can derive no practical advantage from subjecting either inference or the communication of it to any systematic or scientific analysis whatever.

2. The questions thus raised, with others not yet hinted at, will be answered in the explanations now to be offered of the views which have dictated the plan of the following summary. The design of this treatise.

The attempt to sketch a few of the outlines in a theory of eloquence is here undertaken in a spirit, which not only gives a dominant tone to the whole inquiry, but prescribes a selection, not in all respects usual, of questions to be inquired into. The spirit is that of thorough distrust in mere rules of art, accompanied by a faith not less peremptory in those principles on which the rules, if sound, must be founded. If a theory of literature, or of any of its departments, deserves the name it assumes, it is not the road-book of a country perfectly known, through which all men who will submit to guidance may travel with equal safety and equal ease. It is but the code of instructions issued to persons who are arming themselves for an exploring expedition: it indicates distant points to be aimed at, and warns against deviations which would lead utterly astray; but it does most of all towards preparing the adventurer for his task, if it can mark out with clearness the boundaries of unknown tracts, where he must place his sole reliance on his native genius, and skill, and vigour. Such a theory is valuable in proportion to the power with which it prompts thinking, and to the comprehensiveness

Introduc-
tion.

with which it embraces and methodizes the problems that ought to be reflected on.

Now, not only does every department of literature inosculate with every other; but, besides this, literature as a whole is no hermit-cell, filling a sequestered nook in the world of thought. Parallel with the processes which it must adopt are certain other processes, aiming at similar ends by the use of different methods. Literature, again, in common with all those kindred developments of human energy, obeys laws which are really the very same laws that govern common life.

Considerations like these suggest some preliminary inquiries, the result of which will lay, or ought to lay, for all doctrines properly rhetorical, the only foundation that is broad and firm enough to bear them.

I. In the first of the two introductory divisions, the design is that of fixing the place of Eloquence as a member in a group of processes, which will be spoken of as Arts of Communication. The only Literary processes of this system are Eloquence and Poetry; to those which are not literary is usually confined the name of Fine Arts. Some correctness of apprehension in regard to the generic character of the group, is indispensable for the formation of a true creed as to the specific character of any one of the members. All of them obey certain laws in common, and therefore are most instructively studied together, down even to a point far beyond that which can here be reached: they illustrate each other not less aptly by the differences imposed on them by differences either in their purposes or in their instruments.

Further, the two literary arts of communication resemble a two-stemmed tree, whose trunks spring from the same root, and whose branches appear, when seen from a distance, to make up but one magnificent mass of foliage. The comparison between them is instructive through innumerable features both of similarity and of difference. The truth is, that the theory of literature is one organic whole, and should be studied as one system. Not only, however, is such treatment here forbidden, alike by the large space that would be required, and by regard to the reasonable meaning of the title prescribed for the present article; but, likewise, the theory of the nobler art of the two has already, in this work, been sketched by a masterly pencil. (See POETRY.) Nevertheless, many of the facts which it is here sought to subject to law, receive elucidations so pertinent from facts developed in the other great province of literature, that our speculations in Rhetoric will be found, especially in their later stages, to make not infrequent incursions into the domain of Poetics.

II. The second of the introductory divisions is a Psychological Outline.

The maxim must again be urged, that rules of art are worse than futile, unless they prompt reflection on their reasons. All the laws of literature, except those (few and obvious) which depend on physical conditions, are, in common with all others that directly govern any department of man's conscious activity, laws of the human mind or corollaries drawn from these. Rhetoric reposes on Psychology.

Now, though we look no deeper than nomenclature, preliminary explanations are seen to be advisable if not necessary. The use of words and phrases descriptive of mental changes is so loose and fluctuating, that exactitude of analysis cannot be reached without exact determination of the meaning in which the leading terms of this kind are to be used. Here, especially, certain processes are to be exhibited as involving the excitement of Imagination, of Emotion, of Desire: there is not one of the three names that has not several significations; which of these is here assigned technically to each? But the best or only adequate explanation of a name is the description or analysis of the thing; and the aptest explanation of a series of related

names is that which describes the denoted facts in relation to each other. The call for prefatory statement of psychological doctrines could only be superseded by something which cannot be had; that is, by the power of referring to some one system, familiarly known both to writer and to readers, and accepted at all points by the one party as well as by the other.

There is to be offered, accordingly, a sketch of some psychological doctrines, which afterwards will either be appealed to directly in proof of rhetorical rules, or will modify indirectly the aspect in which the rules are presented; or which, if any of them should not have either of these effects, may suggest speculation on questions lying beyond and above the scope of an elementary treatise. The scheme from which those doctrines are taken has been developed gradually as the basis of instruction to pupils. Well-informed readers will perceive that it borrows freely from many quarters. It has owed very much to the suggestions scattered through the *Discussions* and *Dissertations* of Sir William Hamilton, and much also to sources from which that distinguished philosopher has himself drawn. In the final elaboration of the outline, also, such advantage has been taken as the time allowed, of that systematization of psychological doctrines which is supplied by the recent publication of Hamilton's *Metaphysical Lectures*.

III. The body of the treatise is designed for throwing out hints towards the formation of a rhetorical scheme, which would assume as correct the second of the four opinions as to the province assignable to eloquence. A complete system of rhetoric ought to theorize all literary processes, all departments of literature, whose distinctive purpose is not poetical.

Nevertheless, those narrow methods of treatment, which were described as the third and fourth, are faulty only because narrow, not as being erroneous; and they may be adopted, both safely and conveniently, as the basis of any theory aiming at full comprehensiveness.

A few words may be sufficient for explaining the view thus generally stated.

All possible processes of communication through language are reducible to four, distinguishable by these names,—Exposition, Argumentation, Persuasion, Poetical Representation. The last of the four does not fall within our cognizance, unless incidentally. The other three exhaust all the possibilities of method, for language which is used for the attainment of any purpose not poetical. The complete performance of each of them is exemplified in an oration, or other discourse, which aims at exciting volition through motives which must be aroused by antecedent conviction: in such a discourse, exposition is made the groundwork of argumentation, and that again of persuasion. But all other kinds of literary composition, not poetical, are constituted by those very processes, performed in whole or in part, and combined in diversified degrees of complexity. A complete theory of these three elementary and normal processes would lay down all the laws governing the processes which are complex. If such a theory were reached, it would leave for answer, as to each of the mixed kinds of literary composition, three questions only: *first*, which of the elementary processes enter, and which wholly, which in part, into its constitution; *secondly*, which one of the constituents is the process leading towards that which is the paramount purpose of the work, and which of them are no more than ministerial; *thirdly*, what are the relations,—as of comparative efficiency, means of operation, and the like,—between those processes merely subsidiary, and that one into which, as they flow on, they successively deliver their tribute. In a word, the theory of the processes constituting oratory is the true basis of the universal theory of eloquence.

Introduc-
tion.

Accordingly, our business will be the analysis of the three normal processes, Exposition, Argumentation, and Persuasion. This procedure should yield a skeleton-theory of eloquence. Towards the clothing of the bones with flesh and blood, very little can at present be contributed. The application of the elementary laws to even the principal among the complex departments of literature, would require a fulness of illustration which is inadmissible; and the large additional demand on the patience of readers might not seem to be justified by such results as could be presented, in the execution of a design which (perhaps because thought to be erroneous or barren) does not appear to have been as yet distinctly entertained, and has certainly not yet been systematically prosecuted. It must suffice to have offered this prefatory protest against the completeness of the merely oratorical treatment of Rhetoric; and to throw out, as occasion may arise, a few hints illustrative of the opinion thus set forth as to the genuine structure of a complete theory of eloquence.

The practical issue is, that the treatment of the topic has its outline determined by the third of the opinions as to the function of rhetoric. But even the fourth opinion will in some degree affect the scheme.—The analysis of the first two of the three processes supplies disappointingly few materials towards that systematic application to complex instances, which has been asserted to be essential for completeness in the theory of eloquence. As to exposition, although one aspect of it was taken under the especial patronage of Aristotle, hardly any laws can be assigned that touch it properly as a means of communication: success in it is mainly dependent on considerations not in any way rhetorical. The fact is significant, since this is the process which is paramount in history and biography. As

to argumentation, again, the uses of its rhetorical laws are directive rather than critical, a circumstance symptomatic of artificiality; and, further, these uses hardly emerge unless in reference to cases of complicated reasoning in contingent matter, cases occurring frequently in oratory proper, but much less common in works strictly literary.—It is not till we reach the process of persuasion, that it is found possible to elicit laws entitled to claim a commanding place in the code of philosophical criticism. The laws assignable for persuasion justify this claim by their possession of three characteristics: they are resolvable, unequivocally and easily, into principles of man's mental constitution; they possess some efficiency as cautionary guides to performance, and much as suggestive canons of critical judgment; and they govern instances diversified so variously, that there is no department of literature over which they do not exercise some influence. Communication, in short, so long as it seeks to operate exclusively on the rational nature of man, obeys but few universal laws that affect it in its communicative character,—few laws except those which rule the matter communicated, and the thinking which is brought to bear on it. Communication comes under the sway of wide and imperative laws of its own, as soon as it passes onward to the endeavour to generate imagination and emotion. The quarter over which the theory of communication exerts its most active power is the very quarter in which that theory teaches, as the most imperative of its lessons, its own impotence to handle the weapons which native strength of imagination wields with ease,—its own blindness to pierce into the deepest part of those emotive relations, which animate the oratorical picture and idealize the poetic dream.

I. THE ORGANIZATION OF LITERATURE AND ART.

3. The compass of the field which lies before us, in this stage of our inquiries, may be identified when we describe it, in common phrase, as containing Literature and Art, or Literature and the Fine Arts. Our hasty survey is intended for mapping out the ground, in such a way as to indicate the character and boundaries of its several sections.

It is covered by a large system of processes, which will here be spoken of as Arts of Communication.

The name "art" being thus taken to signify processes, not their theories, a group of cognate processes may be called an Art, when they are found to possess two characteristics. First, they must be performable voluntarily, for the attainment of a preformed purpose; secondly, this condition being purified, they will still not come up to the idea of art, until their laws have been more or less thoroughly determined and systematized. If, on this footing, we still wish to retain the use of the current antithesis between the terms art and science, there is only one way of consistently doing so.

The theory of an art, its system of laws, will be called a Science. If, indeed, the name of science is to be bestowed only on systems of knowledge that are in all points both exact and complete, the roll of sciences must always be very short. But imperfection ought not to be a bar; and there may be convenience in sometimes giving the name of sciences to the theories now in question.

If the terms art and science are accepted in the meanings thus explained, the distinction most commonly taken between art and science may, if we will, be recognised as separating science into two sections. The theory of an art is a Practical Science so far as it lays down rules of art, whether directive or critical; the theory of an art is a Speculative Science, so far as it assigns the reasons of the rules. This secondary distinction is narrow and slippery. But it

may sometimes be useful as reminding us, that a rule of art which cannot be philosophically justified is merely empirical and therefore unsafe; and that, both in the study and in the practice of the higher arts, like those with which we are now concerned, a rule has no value whatever, unless for those who have apprehended firmly the principle on which it is founded.

Every art, indeed, must draw its principles from without: it must gather its data, not from one but always from more than one, of those systems of knowledge which serve other uses also, and each of which, indeed, has been or ought to have been constructed, in the first instance, with exclusive regard to the speculative point of view.

All arts are processes of change. Every step is the working of a change: the result, also, is a change, the effecting of which was the purpose towards which the steps were adopted as a means. If all the objects on which an art works its changes are corporeal, or if its result, though mental, rises no higher than sensation (physical comfort, for example), the theory of the art will receive all its data from the physical or mathematico-physical sciences. Similarly, if all the changes worked by an art are mental, the art will derive the basis of its theory from the philosophy of mind,—that is, from psychology, the central and original science of that great cycle. If an art works changes on objects of both kinds, it must borrow data both from the philosophy of body and from that of mind. But, in such a case, the character of the result will decisively direct all the leading steps towards the one side or the other: the rules which properly constitute the theory of the art will be developments, either wholly of laws physical, or wholly of laws mental; and the subordinate laws, whose operation is merely a condition of the possibility of the art, may be silently assumed.

In all processes describable as arts of communication,

Organiza-
tion of
Literature
and Art.

man attempts to work on the mind of man, either individually or collectively. Each of them is constituted by steps, in which, mental states having arisen in one mind, it is attempted to communicate these to some other mind or minds; and the purpose of all is the effecting, in that other mind or minds, of changes of one kind or another. Many processes falling under this description (for example, the process of education) are complex in the extreme: the communicative process has to be repeated indefinitely often; and it has to be engrafted on antecedent processes, requiring to be separately theorized.

As normal specimens of the arts of communication, there may be taken those processes which are embraced under the name of Literature, and those others to which (too narrowly) is usually confined the name of the Fine Arts. All processes of the first class fall within two arts,—Eloquence and Poetry. Among processes of the second class there are only three arts which can be considered as being at once pure and complete,—Music, Painting, Sculpture. If the theories of those five arts can be established, the ground is laid broadly enough for the theorization of all other arts of communication, so far as they are merely communicative.

Literature
and art—
the pro-
cesses and
their theo-
ries.

4. The character of an art is primarily and most widely determined by the character of its purpose. All the arts of communication have this in common; that the effects they aim at producing are mental changes, and changes rising higher than sensation. Consequently the paramount laws of all of them are laws of mind.

The consideration of purpose yields, further, a primary distribution of those arts into *two classes*. Their primary and paramount differences are founded on differences in the mental states, the modes of mind, which they severally aim at communicating. It is only secondarily, for the formation of genera within each of those two classes, that account can be taken of those differences which arise out of differences in the means or instruments.

Having regard to purpose, then, we have first to set aside, as constituting the first of the two classes, all those of our five arts which have for their distinctive and paramount purpose the excitement of feelings (specifically emotions) having a certain character. These are oftenest called feelings of Beauty. At the cost of a little anticipation, they may be described as feelings of imaginative pleasure, or as pleasing emotions consequent on imagination. All arts entertaining this purpose have a claim equally strong to be called Fine Arts; and all of them will here receive that name. Indeed this phrase is merely an indistinct translation of terms common to all the continental tongues, and more correctly rendered, "the beautiful arts," or "the arts of beauty." The fine arts of our roll, then, are four of the five: poetry is a fine art, as properly as music, painting, and sculpture.

The universal theory of the fine arts, the system of laws which is obeyed by all of them, and by the study of which the way ought to be prepared for the study of each of the special theories, has received the name of *Æsthetics*. The word is but indistinctly descriptive, and has likewise been used philosophically in other meanings. But it suggests significantly the working of all the processes towards feeling; and no substitute that has been proposed is free from faults of other kinds.

Overagainst those arts stands the second class of our arts of communication, into which must be admitted all processes aiming distinctively at the communication of any mental state different from imaginative pleasure. For processes of this class we cannot gain a name, till we have descended to the consideration of the means or instruments. Then, also, the true rank of poetry will appear.

Plain it is, that instruments may be fully available for the end entertained by the fine arts, and yet quite inade-

quate for the attainment of all the purposes aimed at by the processes constituting the second class. The truth goes even farther: while several instruments are adequate for the first purpose, there is only one instrument fully adequate for any of the others. All these other purposes are, for the uses of theory, reducible to two (the purposes of communication being thus, in all, no more than three). First, the design may be to generate cognition or thought, in the form of Belief, Judgment, Explicit Knowledge; secondly, the design may be to generate Volition (an act of will), through Imagination and consequent Desire or Aversion. It is conceivable (rather than likely) that in communication the modes of mind aimed at shall not be either of the two here named. But if so, they must be modes which are steps towards the one or the other of the two; and a complete theory of the processes leading to the two must have accounted for each of the steps.

For the generation of Belief and Volition through communication, no instrument is fully available except Language, Articulate Speech, spoken or recorded. Belief consists in, volition presupposes, clear thinking of the character and relations of objects; and such thinking cannot be conveyed from mind to mind,—cannot, indeed, take place even in one mind,—through any machinery less powerful and flexible than words.

Accordingly, the only processes of communication admissible into our second class are those which may, in a just sense of the word, be held to be contained in and constitute the Art of Eloquence. To the theory of that art there has been allowed, ever since the Greeks bestowed it, the name of Rhetoric.

Further, processes which communicate through language, and those which communicate otherwise, may conveniently be distinguished as Literary and Non-literary. Eloquence is, among the communicative arts which are not fine arts, the only one that is literary. Among processes of the other class, Poetry is the one fine art which is literary; the others are not discriminated exactly enough till they are described as being Fine Arts Non-literary.

If we were to enter on a particular consideration of the several theories of all those arts, the differences of instrument would come decisively forward, and dictate a distribution guiding our course of study.

On the one hand would stand the Theory of Literature; or, as it has aptly been called, the Philosophy of (literary) Criticism,—a name hinting, significantly and instructively, that the use of theory here is critical rather than directive. This theory is constituted and exhausted by two special theories, or sciences, if that word be allowed: by the theory of Eloquence, which is Rhetoric; by the theory of Poetry, which likewise may retain its old name Poetics or Poetic.

The psychological *præcognita*, the instrumental presuppositions, required by the theory of literature, are derived from the science of Grammar; that word being understood in the wide meaning it ought to have, as including both the universal theory of language, and the special theory of the tongue on whose literature the doctrines are designed to bear. The frontier, indeed, which fences off rhetoric on its lowest side from grammar is as loosely drawn as most of those other lines of demarcation, forced on us by the necessity of apportioning human labour. All laws of Style might be said to be, in strictness, grammatical, not rhetorical; but by the total exclusion of these the practical uses of rhetorical study would be injuriously cramped. On its higher side, again, rhetoric finds itself to be often brought into direct and useful contact with poetics; and it may learn much, by contrast, from the general doctrines of æsthetics, with something now and then from the special theories of the several fine arts. Poetics, while standing in intimate relations with rhetoric, is necessarily in close alliance both with æsthetics, on which its own uni-

tion of
Literature
and Art.

versal laws are founded, and with those special developments of æsthetical laws which rule music and the arts of design.

The physical præcognita of the theory of literature are so narrow, and so patent, as scarcely to require being alluded to. The case stands very differently with the non-literary fine arts. On all of them, though not with equal breadth of application, their nature imposes it, as a condition prerequisite, that those objects of perception which are their instruments shall be on the whole sensuously agreeable. With the harmony of colours, which is thus a condition imposed on painting, and weighing, though lightly, on sculpture, we are not concerned. But we are interested in the harmony of sounds, which penetrates so deeply into the essence of music as to threaten continually an ignoring of the higher capabilities of the art. Poetry, being a fine art, and operating through sounds, has to accept audible harmony, in a certain modification, as one of its precedent conditions; and the melody of language gives a fine and attractive charm to the higher and more imaginative efforts of eloquence.

Among the differences in procedure, necessarily modifying the results likewise, which are imposed on the several arts of communication by the differing character of their instruments, there may here be indicated, in brief, one or two which will soon supply us with instructive points of comparison. On the rhetorical side, these affect exclusively processes in which the excitement of imagination is a step.

The difference which pierces deepest is that which separates the literary arts and the non-literary.—The latter excite imagination directly: the excitative power is in the work of art itself, constituted by the group of visible forms and colours, or the series of audible sounds. We see the work or we hear it; and, if the perception ceases, our image might supposably be a mere representation of that which we had perceived. Indeed the object actually perceived plays so prominent a part, as to incline towards misleading both theory and practice. The cardinal doctrine, that all the fine arts work their genuine effect only by exciting the imagination of the recipient, is hardly questioned in its application to poetry. But it is not so obvious, nor yet so readily admitted, that the same law rules the arts of design. For here the force and clearness of the perception tend not only to tempt away from the imaginative effort, but also to hamper its freedom when it is instituted; and, beyond all doubt, the mere sight of a picture or a statue imparts a certain kind of pleasure to many minds, whose sluggishness of imagination incapacitates them almost utterly from profiting by the higher suggestiveness of the work. In regard to music there occur similar doubts, traceable, however, to other causes. The organic gratification derivable from harmony of sound is so intense and so fine, that it is apt to monopolize the attention of one who is keenly susceptible to it; and, further, the images directly suggested by music are vague and indistinct, not rising into clearness and precision unless in minds which exercise an independent force of fantasy, closely allied to that which generates the poetic mood.—In imaginative eloquence, exactly as in poetry, the instrument through which the effect is produced, that which is communicated and excitative, is not really the words, but the thoughts which the words signify. Notice will be particularly invited hereafter to some of the interesting consequences flowing from the merely mediative function of language, and from the symbolic and conventional character of the words by which it is constituted.

Another difference, secondary but yet very important, subsists between the arts of design on the one hand, and the other arts of our list on the other. The former represent in space; the latter represent in time. It will be shown that this contrariety, which is oftenest put to use in the theory of poetry, is also fruitful for eloquence both in

restrictions and in licences, both of which are not infrequently ignored.

5. When it has been thought worth while to characterise thus systematically the theories of arts, some explanation may be proposed as to the practical bearing which the theory is likely to have on the relative art.

No defence is needed for the dignity and value of speculation as speculation. Equally needless is it to say, that every practical science has speculative relations, which might justify its claim to attention though its practical usefulness should be very small. The theory of every art has a general speculative value, as being (if rightly founded and constructed) an organised system of truths: the theory of all the arts now in question has also a specific speculative value, as being the product of systematic thinking, applied worthily to the monuments of literature and refined art. The thoughts, and images, and feelings which are poured out by the hand of genius, cannot be imbibed by us without the rise of an earnest longing to discover some at least of the laws, in virtue of which it has become possible so to elevate, and inspire, and move us. Inquisition into the laws of literature, and its kindred arts, would be alike inevitable and praiseworthy; although it should be certain, as it never can be in regard to any speculative truth whatever, that the attainment of even a complete system of laws for the kind of processes examined must remain practically barren.

The theory of an art can have but either or both of two practical uses. It is Directive, so far as it is efficient for guidance in the construction of new works: it is Critical, so far as it assists in the just estimation of works already constructed. Of no art whatever can the best possible theory serve either use in any but a most imperfect degree. The higher and wider an art is in the results it aims at, the weaker does its theory become in both aspects; and, when we reach arts having the elevated and far-reaching character of those we have here to do with, the directive use of theoretic laws has nearly vanished, while even the critical use has shrunk within narrow bounds. In the lowest arts that are conceivable, successful performance has individual aptitude as a condition precedent: in arts of high compass this aptitude assumes, more and more as we rise, the character of that which is called genius. Such laws as can be assigned come then to have a direct value that is only negative. They are warnings that disobedience will, though the native power be present, impair or destroy the effect aimed at.—The discovery of the assignable laws rests primarily on the study of works already in existence; the laws cannot confidently be pronounced to be sound, unless the possibility of mistake is excluded by a wide range of antecedent experience. Even such laws are obeyed by genius, rather in accordance with its own imaginative instincts, than in consequence of distinct and generalised thought. Nor do such laws as are assignable serve any higher office than that of being guards about the doorways of the temple: genius sits alone and unapproachable in the sanctuary which is within. But theory has given us something well worth having, if it has only taught us how far law, consciously generalized and intelligibly promulgated, can penetrate into the heart of those mysteries, in the midst of which the poet, the orator, and the artist live and work through feeling rather than thought. It is much if there can be drawn, though it should be but dimly and waveringly, the line beyond and above which rules cease to have so much as critical force.

In a way generally and distantly suggestive, however, rules have a positive efficiency; an efficiency which, even in the arts of communication and in the most ambitious phases of these, may be made to manifest itself vigorously in criticism, and to affect beneficially performance likewise.

The rela-
tions be-
tween arts
and their
theories.

Data for
Theories of
Literature
and Art.

It is said that in the history of the arts practice precedes theory; and the assertion is correct in a sense which the foregoing hints imply. It is not true, even of the arts of communication, that any of them, or any department of any, is ever practised in the absence of all intelligent apprehension of its governing laws. But it is true that all of these arts are practised, and attain eminent success, before the attempt is deliberately made to discover all the discoverable laws, and to digest these into a theoretical code. A theory, however, being once attained, cannot but exercise and deserve to exercise influence on the subsequent history of its art, so far as it is sound and limited to its legitimate duties. Such influence belongs rightfully to those wide theorems, in which it is possible to exhibit the character of literature and art as an organic system, and the characteristics, generic and specific, of each of the members by which the system is formed; and it belongs with equal right to many particular laws, or cautions, or hints, which are validly deduced from the ruling principles of communicative art as a whole, and of each of its constituent sections. Violation of the particular laws will involve error proportional to the width of the law disobeyed; error which, though no exposure of it should be made by reference to reasons, will be discovered to be error by the native instincts of those to whom the work is addressed. Violation of the wider laws will work still more hurtfully: and this, like the other, will be punished and betrayed by failure in result; by failure which, sooner or later, is certain to be suffered, and which will be speedy or immediate if public taste and judgment be refined and correct.

Not to be overlooked is a class of facts, which is interesting in itself, while it often embarrasses attempts at applying the laws of art to individual works, especially in literature. The theory of an art must be founded on an exact determination of its purpose and procedure, as these are exhibited in the purest instances that are possible. Now, in the actual uses of the non-literary arts there is some scope, in communication through language there is large scope and almost continual occasion, for combination of purposes and consequent complication of processes.

In respect of literature, it has already been asserted, that those genuine departments of it which are not poetical in aim, are really combinations of three normal processes, or of certain of their steps; and, if our business had led us to close scrutiny of poetry, we should have found reason for believing that its genuine kinds likewise are to be regarded as similarly products of a very few elementary forms. The difficulties which are thus raised, even when eloquence and poetry remain faithful, each to its own distinctive vocation, must make literature chaotic and criticism feeble and incoherent, unless the paramount principles of communication, and at least some of their nearest corollaries, be steadily kept in sight. Powerful effect cannot be worked by any literary work without unity of purpose; and the character of the purpose will determine that of the processes,—both of the process which leads to the main result, and of those which are grouped round it as leading to the attainment of aims that are subsidiary.

The principles of
psychological
method.

6. All the actual phenomena of mind are complex. This ought to be the first and fundamental article in every psychological creed. We must not take it for granted, that factors or elements which we can think of separately are always possible in isolation. But it is through different combinations and modifications of a very few elementary factors, that actual phenomena of mind gain their indefinite diversity of character; and therefore the abstractive and ideal separation must be carried up to the very highest point which analytic thinking will allow.

Data for
Theories of
Literature
and Art.

There may be combined in one work, however, processes which ought not to have been so, because leading towards or up to purposes which are irreconcilable and mutually destructive. Therefore, in all those complications which are so common, the question of legitimacy or illegitimacy must be firmly dealt with. Every art of communication is tempted to struggle for the enlargement of its sphere; mutual borrowings take place between processes the most hard to be harmonized: and, while this dangerous ambition often paralyzes instantly the work in which it is indulged, it imparts still oftener nothing better than the momentary vigour of a feverish paroxysm succeeded by utter exhaustion.

In one sort of cases, the purpose of the art is neither lost sight of nor mixed up with the purpose of others; but the means appropriate to it are enlarged by the addition of means which are foreign. There arises no risk of throwing the process out of the class it should belong to; and, the laws thus retaining firm hold, the error, when gross, is easily discoverable, and almost always exposed. In this way the arts of design borrow from each other; and each of them sometimes, but most unwisely, borrows objects or aspects from poetry. It is a fact coming closer to our inquiries, that poetry often seeks to represent objects and aspects of objects, not representable unless through the means available to painting and sculpture. Eloquence imitates the error; and it will be dealt with hereafter.

Cases of another sort are much more dangerous and troublesome. They consist in complications, interferences, or uncertainties of purpose. Out of these spring works of art, which, when their divergence carries them so far that they do not acknowledge as paramount the laws of any one art, really constitute composite classes, in which theory is set fairly at defiance. Literature is especially open to formations of this cast, on account of the precision of language and its indomitable elasticity; and accordingly few generations have wanted occasion for paying just admiration to the fine thinking, or imagination, or feeling exhibited in works which, still veering doubtfully, like a ship under shifting breezes, between the aim of poetry and aims not poetical, are only dazzling effusions of genius, not thoughtful and enduring monuments of literary art. In the early and spontaneous development of literature and the arts of design, an approach is made to this treacherous ground; but the simple old poets and artists are protected against its dangers by their own strong simplicity as well as by the comparative poverty of their means. It is not till the literature of a nation has passed through its summer-gloves, and is descending into the coolness of its autumn, that the boundaries separating the provinces are wilfully overstepped: they are so by men of high literary powers, ambitious of gaining originality of effect through forms unlike the old, and through aims in which the old ones are perplexingly intermingled. An instance, for which no good defence can be offered, is the didactic poem: in the prose novel and romance there is an instance which might be defended by a thousand plausible reasons, and by a few that are strong enough to vindicate for it its place as a somewhat rebellious dependence of the poetical empire.

II. THE DATA FOR THEORIES OF LITERATURE AND ART.

The arrangement of mental facts in named classes is equivalent to an assertion, that each class obeys laws, for which the name is an abridged expression; and the compass and mutual bearing of those laws is indicable through the ordination of the classes, as exclusive of each other, or as descending in regular order of specification.

Every mental fact is doubly related. It is related primarily to the mind, which is its subject; and out of this subjective relation arise its widest and overruling laws,—the characteristics which appear to belong to it when it is con-

Data for
Theories of
Literature
and Art.

sidered as a function of mind,—those which would suffer no change through any change of object. It is related, secondarily, to the object or objects with which it brings the mind into communication; and out of this objective relation arise subordinate and modifying laws,—laws in virtue of which every subjective law puts on different characters according to the different objects with which, in a given case, it connects the mind. When this principle is applied to the framing of a synthetic psychological scheme, it yields a distribution of all mental laws into orders, which become narrower and narrower. In the study of those orders, we take our departure from subjective laws which are universal, as governing all mental facts: we pass thence to subjective laws which are particular, each governing only certain kinds of facts; and thence we travel downwards still, in several degrees, through narrower and narrower groups of objective laws, which are closer and closer particularizations of the subjective laws that are particular.

The uni-
versal laws
of mind—
conscious-
ness and
retention.

7. All mental laws which are both subjective and universal, are virtually covered by this assertion: that all mental facts are facts either of Consciousness or of Retention.

(1.) Consciousness is the mind's knowledge of its own phenomena; a knowledge necessarily including a knowledge of the objects. All mental *phenomena*, that is, all mental facts of which we have direct cognisance, are facts of consciousness. All the kinds of mental phenomena, all forms of mental manifestation, are modes or varieties of consciousness. Thus also, in the last analysis, all modes of consciousness are facts of knowledge or cognition.

Consciousness, considered more closely, is the mind's knowledge of all that is Present to it in time and in space. But we can and do and must think of objects, which are not present in either of those relations. Especially it is true, that we do and must think of the Past; and it is through the past that we think of the Distant. We remember what we seemed to have forgotten: that which has once been known does not lose its relation to the mind through our ceasing to think of it. Through the past and the distant also, we are able to think of the Possible.

(2.) Facts of Consciousness are Retained by the mind; but the retention occurs unconsciously, out of consciousness. That a fact of consciousness which a mind has once had, continues, when it is past, to stand related to that mind,—to be an attribute of it, a step in its history by which subsequent steps may be consciously influenced,—is a truth which we cannot prove directly, since we have no immediate knowledge of such a relation; but it is a truth demonstrable *ex impossibili*, through that conscious revival of the old fact, which could not take place but for the unconscious retention of it.

Thus there is one class of cases, indisputably real and immensely wide, in which mental facts are not phenomena, that is, facts directly observable; cases in which they are facts latent, detectible only through their consequences. Therefore it requires only another step (but that a wide one) to carry us into Leibnitz's hypothesis of modifications of mind, which, instead of merely becoming latent, are latent from the beginning.—It happens very frequently that a thought now in the mind cannot be accounted for, unless we suppose it to be the result of an antecedent mental process, of none of whose steps are we now conscious. It is commonly maintained that those steps must have taken place in consciousness, but have been forgotten through a want of attention. It has been alleged, however, as a less strained supposition, that the missing steps, though actually occurring, have never been in consciousness at all. The hypothesis might yield a plausible solution of some difficult cases in which the rhetorical student is interested.

(3.) The Past, then, having been retained unconsciously, comes again into consciousness, indirectly, in a kind of fact

Data for
Theories of
Literature
and Art.

which, regarded from different points of view, may be called either Reproduction or Representation. The object of this new fact is a thought constituted, in whole or in part, by factors or elements similar to those which constituted either a past fact of consciousness, or more than one such fact. The new fact may thus be said to reproduce the old, or to represent it,—in respect that the former makes present to us, and thus brings within the sphere of consciousness, something which we can think of as equivalent to the latter.

In this way consciousness yields us two kinds of knowledge. We have an Immediate or Presentative Knowledge of that which is present, but of that only; and, through and in such knowledge, we have a Mediate or Representative Knowledge of that which is not present, but once was so. The distinction affects all modes of consciousness to this effect; that past phenomena belonging to all of them may be reproduced, and thus known mediately. But so much as we require here to learn, in regard to the specific laws of both kinds of knowledge, will be considered more aptly at a later stage.

8. All possible modes of consciousness are primarily distributable into *Two* great *Classes*, distinguished by a difference very deeply marked, and related by a law which is for our purpose extremely valuable. But the characteristics of those two classes will become clearer when, by taking a second step of specification, we have got possession of names to which precise ideas are attachable.

Primary
distributions
of the
elementary
modes of
conscious-
ness.

Examined more closely, but still with a reference as purely subjective as the nature of mind will allow, the two classes are found to be constituted by *Four* several and distinguishable *Modes of Consciousness*, which may be described as *Elementary*. These, in some or other of their objectively determined varieties, are the factors of all complex mental phenomena.

All mental phenomena, then, must be facts either of Feeling, of Knowing, of Wishing, or of Willing.—Under the name of Feeling come all facts which, by a further reduction still subjective, are describable as being facts either of Pleasure or of Pain. It is convenient, also, to lay down at once the broadest of the objective distinctions separating the kinds of feeling. A Sensation is a feeling whose excitant is a phenomenon of the body of the subject: an Emotion (the "sentiment" of Hamilton and others) is a feeling whose excitant is a phenomenon of the consciousness of the subject.—Under the name of Knowing or Cognition come all facts which could rightly be said, in the current terminology, to be operations of intellectual powers or of powers or faculties of the understanding.—The term Wishing is here used to denote operations referable to the "active powers" or "active principles" of Reid and Stewart; being extended, however, so as to embrace both of their alternative forms. A positive wish is a Desire; a negative wish is an Aversion.—The term Willing or Volition is used in its universally-received sense, and is equivalent to such words as Resolution or Determination.

Let us now fall back on the primary distinction of all those modes into *Two Classes*. The first class contains Feeling alone; the other three modes constitute the second class.

The classification arises out of the antithetical correlation between subject and object. The relation of the phenomenon to the mind of which it is an attribute is constant and unalterable; the relation of the phenomenon to that with which it connects the mind is occasional and variable. The differences between all modes of consciousness, down to their narrowest objective varieties, consist simply in varieties of the objective relation, modifying by reaction the relation which is subjective. Feeling stands alone, as being, through its objective relations, the one mode in which consciousness is imperfect, merely rudimental, and yields a knowledge that is confused. The other three modes stand

Data for
Theories of
Literature
and Art.

together, in respect that in them, through their objective relations, consciousness is perfect, fully developed, and yields a knowledge that is clear.

Alike in Knowing, in Wishing, and in Willing, the mind has consciousness of an object, which either is actually, or is thinkable as being, different from the mind itself. In Cognition pure, the mind has such consciousness, but it has nothing more: it rests in contemplation of the object; the balance of the two counter-relations is in equilibrium. In neither of the other two perfect modes is that consciousness lost or even obscured: they differ from cognition, and rise above it, because in each of them a new element is added. But the addition made in Wishing throws the fact towards the subjective side; the further addition made in Willing throws it towards the objective. In Desire or Aversion, the mind is bent backward or downward towards the thought of itself. The object is thought of as standing towards the mind in a relation which is imperfect and unsatisfactory: the idea of change has come up; and the mental state is one of transition. In Willing there are all the elements of Wishing; but there is also something which is new and higher. On the idea of change there is engrafted the idea of power to effect change: the mind, through the exercise of its own energies, thinks itself into the closest possible relation to its object: the equipoise of relations, disturbed by wishing, is restored; but while in cognition the equipoise was determined *for* the mind, it is now determined *by* it. Thus, wishing is indeed more than pure cognition, and willing is more than wishing; but in neither does there disappear that thinking of an object, which is the characteristic mark of cognition proper.

The want of this characteristic mark is the distinctive feature of Feeling; and the want sets this mode in contradictory opposition to the other three. In feeling pure and proper, in being conscious of pleasure or of pain, the mind knows merely a state or modification of its own: it cannot know anything else, without rising into a higher mode. Some object or other must have been the excitant; but, so long as the mind merely feels, that object is hidden from it. Pure feeling has no object beyond itself, no object either actual or even thinkable. The objective relation is the slightest that allows consciousness to be possible. If we are to suppose that any one mode of consciousness can, at a given time, possess the mind to the entire exclusion of all others, we must admit that the mind, in being conscious merely of pleasure or of pain, is conscious only in the very lowest degree.

Here, if anywhere, is to be found the root of that plurality of conflicting elements, out of which the mind strives incessantly to rise into the unity of clear consciousness. The germ cannot be detected through any working out of the concrete and complex antithesis between understanding and will, knowledge and endeavour. It is to be sought in the recognition of consciousness as being itself knowledge; and in the subsequent acknowledgment of the distinction between that one phase, in which the mind falls back on the mere knowledge of its own states, and those higher and successively ascending phases, in which it knows and desires and strives after an object real or thinkable. There is a plain contrariety of character between the one imperfect mode of consciousness on the one side, and the three perfect modes on the other.

But there is likewise between the two kinds a close and indissoluble connection; and it is for the sake of this connection that the relations of feeling to other mental modes are here important.

9. The doctrine to be maintained is this.—In the first place, whatever other complexities may be discoverable, every actual phenomenon of consciousness is at least complex to this extent, that it contains two simultaneous fac-

tors: the one referable to one of the perfect modes, a cognition, a wish, or a volition; the other belonging to the imperfect mode, that is, a feeling.—Secondly, the phenomenon derives its unity from the necessary predominance of the one factor over the other. The subjective factor (feeling), and the objecto-subjective factor (cognition, wish, or will), co-exist in an inverse ratio; and the factor which is the more intense obscures the other, or may by possibility conceal it. The complex phenomenon is named and thought of by us, and may often be treated safely even for philosophical ends, by reference to the factor which is predominant over the other.—Thirdly, in any continuous mental process or series of successive steps, those steps in which the perfect factors are predominant are the most obviously important, and therefore attract notice most readily. Thus we might be tempted to describe the necessary antecedents of action proper as being three only,—cognition, wish, volition. But the feelings which those overruling elements have kept under while themselves present, tend continually to rise into prominence in their turn; so that a mental state which we should describe as being distinctively an emotion, may consciously occur between any two of the three leading steps.—Fourthly, these intervening emotions, so called, which are properly complex states having emotion as the ruling factor, must be of very short duration: the mind spontaneously tends to rise into some of the higher modes, or into a state in which one of the higher modes is predominant. Yet in every energetic process of mind, such flashes of emotion, such sinkings back from intellection or the modes still higher into intervals in which the predominating consciousness is only of pleasure or pain, are incessant and unmistakeable. It may even be alleged, that the vigour of a mental process is proportional to the degree in which feeling thus wells upwards: indeed it is only so that we obtain the full consciousness of that pleasure or pain, of that effect worked or workable on our own being by the objects we contemplate, out of which springs the very life equally of thought and desire and will. Thus, for instance, a vivid image obscures for a moment the concomitant pleasure; but immediately the emotion recurs with an intensity proportional to that of the image which had at first overpowered it.

That feeling is, very frequently indeed, consciously co-existent in time with the higher modes of consciousness, is an assertion which is not contradicted either by ordinary thinking or by any sound philosophical doctrine. Most men would admit that a thought or desire or act of will is, usually at least, either pleasant or painful in one degree or another. Hints or direct assertions to the same effect are common in psychological systems, though left unworked by reason of the little attention that has been given to feeling; and doubts as to the simultaneity would hardly be prompted, unless by misunderstanding of the doctrine (true in one sense, and false in many others), that the mind cannot be in more than one state at the same time. The one real difficulty is, the accounting for cases of seeming exception; and this difficulty is removed by the law of the inverse ratio. Without seeking for any solution more abstruse, such as that of latent modifications, we can easily conceive how either element of the complex fact, being known but obscurely at the time of its occurrence, and being therefore unattended to, may gain no hold of consciousness strong enough to make it be retained and reproduced.

The law of the *inverse ratio*, propounded by Hamilton, and by him elaborately illustrated in its specific application to the counter-relations between Sensation and Perception, is by him also extended to the relations between Feeling of all kinds and Cognition of all kinds. If the law be admitted at all, it is not easy to see how it can be arrested at this point of development. Wishing and willing, having

cognitions as their necessary antecedents, and being themselves not less than cognitions, but more, must carry through with them all the conditions of cognition. And the extension of the doctrine over the whole sphere of consciousness, to the completion of the antithesis between feeling and the perfect modes, seems to be imperatively required, for placing in full light the wide function of feeling, exercised so incessantly, yet so apt to be overlooked.

The doctrine has thus been pressed to its complete development, in order that the processes afterwards to be explained may be open to receive the deepest grounding of which they are capable. But the use which must necessarily be made of the doctrine in the present inquiry is limited in two directions.

These psychological data are chiefly required for our analysis of the mental process which issues in action. In that process, let it take the very simplest form of which it is susceptible, there are three governing and predominatingly objective steps, distinct and successive. There is, first, a fact of Cognition, and specifically of Imagination, a fact in which an object is imagined: there is, secondly, a fact of Wishing, in which (the positive form being at present adequate as an example) the object is Desired: there is, thirdly, a fact of Volition, in which there is resolved on an action, judged likely to produce the attainment of the object. Now, the character of this process is most insufficiently understood, unless due account is taken also of the repeated emergence of Emotion, the subjective concomitant or condition of those objective changes. The character of the emotion, the manner in which it is modified by the character of the excitant, cannot be thoroughly accounted for, unless on the supposition of the original simultaneity. But, as it has already been asserted, if the objective step has been energetic,—if the cognition has been distinct, the desire intense, the volition vigorous,—the concomitant emotion, subdued at the time, will come back with a rebound, and present itself as the determining feature in a succeeding mental fact. In this way emotion may intervene consciously and energetically between any two of the objective steps, and cannot fail to do so if consciousness is in due activity. The rise of the mind from the image to the desire, and thence to the volition, will take place, not with the uninterrupted swell of an inundation, but with an alternation like that of the flowing tide of the sea. Ascending waves of thought carry us steadily upward; yet, after each of these, there is a reflux into emotion: we fall back for a moment on self-contemplation, with no loss of ground, and with a resulting increase in the power of the impulse. Feeling exercises, as if by a repetition of quick electric shocks, its characteristic function, of mediating between mind and its objects, of keeping awake and heightening the mind's interest in the persons and things with which it deals, by incessantly recalling to it their effects on its own internal state.

Now, in the first place, the appeal to the primary doctrine being kept open, in order that difficulties may be explainable and rules philosophically justifiable, it will usually be alike safe and convenient, that we accommodate both our treatment and our names to such cases as those which were last described; to cases in which, the objective steps taking place vigorously, the concomitant emotions recur as intermediate steps. It must be asserted emphatically, that the mental process which Persuasion aims at exciting is not rightly excited unless it has this character; unless, through the energy of each cognitive or higher step, the emotion does recur as the prominent and distinctive factor of a step succeeding. Thus, the first step, in which the emotion is decisively in the back-ground, may be described as consisting essentially in the formation of the Image: a second step, which should intervene between the image and the desire, may correspondingly be described as an Emotion.

VOL. XIX.

Literature
and Art.

Secondly, though we are interested in the whole process down to its consummation in action, all rhetorical rules that can confidently be prescribed bear only on the two steps last noted, the first two in the series: the originating objective step,—that is, the fact of Imagination; the subjective step which next interrupts the objective series,—that is, the fact of Emotion.

Explanations are now called for as to each of the four elementary modes of consciousness separately.

10. The doctrine of Feeling has necessarily been in great part anticipated.

It has been asserted that, primarily and subjectively, Feeling must be either Pleasure or Pain. Every state receiving either of those names is distinctively a feeling; and the actuality and importance of such states ought to secure for feeling, in every psychological scheme, a place very unlike the obscure corner which, in our country at least, has usually been allotted to it. Contrariwise, a feeling which is neither pleasant nor painful is a thing inconceivable. But pleasure or pain *absolute* should be distinguished from pleasure or pain *relative*, which is consequent on the diminished intensity of a feeling of the opposite kind. So, further, there are certainly *mixed* states of feeling in which, however, either pleasure or pain must predominate. Moderate degrees of pleasure or of pain are designable by such names as the Agreeable or Disagreeable; and in the complex ideas signified by such names as Happiness or Misery, continuity of pain or of pleasure seems to be the element indicated most prominently.

There has been stated, also, the objective distribution of feelings into Sensations and Emotions, distinguishable by the character of their antecedents or excitants, these being respectively phenomena of the bodily organism of the subject or of his consciousness. This principle of distinction is quite reconcileable with the doctrine of the simultaneity of feeling with the higher modes of mind.

Of the many specific distributions both of Sensations and of Emotions, which emerge through relations to the diversified kinds of excitants, there are but few which here concern us.

It is of some interest to us, and would be of much if we aimed at a universal theory of the fine arts, to note the difference between two varieties of Sensation, both of which place the subject (all sensations do not) in relation to bodies external to his own.—The first contains those sensations which are the subjective concomitants of ordinary perception.—The second is peculiar to two of the senses, those which are most decidedly objective it contains those peculiar sensations of sight and hearing, which are excited by colours and sounds related harmonically. Sensations of this group have great æsthetic value, as being preliminary conditions of the operation of the non-literary fine arts; while a modified pleasure from melody of sounds has a corresponding though less prominent place in literature likewise, operating more widely in poetry, less widely in eloquence.

Of the indefinitely numerous classifications of emotion which emerge when it is regarded from different points of view, there are two which claim our notice.—We are interested, though but indirectly, in the distinction which separates emotions excited by cognition of objects placed in moral relations to us, from those excited by objects contemplated as in relations of any other kind. Emotions of the former group are the moving power in mental processes ruled by conscience, the moral faculty.—The other objective distinction tells more closely on our inquiries. Emotions, whether pleasant or painful, excited by our cognition of objects placed in certain relations to us, tend to rise directly into wishes,—into desire in certain cases, into aversion in others. Emotions excited by our cognition of objects

placed in certain other relations to us have not that tendency, but tend to fall back into cognition; and such emotions are always pleasant, or have pleasure as their overruling characteristic. This Emotive Pleasure, not excitative of desire or aversion, but purely Contemplative, is, as we shall soon have occasion to observe more exactly, concomitant in the first instance, and consequent in its recurrence, on a cognition specifically describable as a fact of Imagination. If, looking back to the view we have already obtained of the process issuing in action, we re-consider the first two steps, the image and the emotion, we shall understand the circumstances in which this contemplative pleasure arises, by supposing that process to be arrested at the second step: the emotion, instead of passing on to desire, reverts into imagination or some other phase of intellection. A state of pleasing emotion, having such an origin and such an effect, is the mental state towards the generation of which poetry and the other fine arts characteristically strive: poetry is, then and then only, purely and exclusively poetical, when the pleasure which it excites fulfils those conditions; and the broadest distinction between persuasive eloquence and poetry is before us, when we regard the former as generative of the complete process which is consummated in action, the latter as generating the earlier steps of that process, but these only. The name of Beauty, originally and strictly applicable to visible objects, in reference to certain of the feelings which the cognition of them awakens, has been currently extended in our philosophical and critical literature, so as to embrace all varieties of this contemplative pleasure immediately consequent on an act of imagination.

If we were to attempt accounting fully for the rise of such imaginative pleasures, we should be thrown back gradually on the question as to the origin of pleasure generally; and this inquiry would issue in the theory, which determines all pleasure to arise out of the consciousness of mental activity, exerted on objects which neither confine nor overstrain it. Among the many specific modifications, however, which this law receives, and which must be brought to light before the theory can be applied to any given case, there is one which, as being operative widely and incessantly both in persuasion and in poetical representation, has for us great value.

The modification alluded to is yielded by the great Law of Sympathy, expressible, with small alteration, in the words of Adam Smith: The mind has a tendency to experience feelings which it perceives to be manifested by others. It is not here needed to propose the problem, whether this strong and beneficent tendency be an ultimate law of mind, or whether it may be resolved into laws still simpler and deeper. The law must be accepted in the shape in which we know it to be operative; and in the later stages of our inquiry it will seldom be far out of our view.

The laws
of cognition—
judgment—
—imagination
and
conception.

11. The theory of Cognition, supplying the data for inferences in ontology or metaphysics proper, is the favourite battle-field of philosophical controversy. With the more profound of the analytic problems raised in it we are not here directly concerned. The theory of comparative judgment, again, though we require to use it in some degree, is supplied by any reasonably correct system of logic. What we cannot command so readily, while we need it especially, is a clear and consistent theory of Imagination; and even of the kind of cognitive facts so named, the character cannot be fully elucidated without some consideration of its relations to other phases of intellection.

The widest of all distinctions within the sphere of cognition, is that which the logicians mark by the two names, Apprehension and Judgment. Every fact of knowledge must have the one or the other of the forms so called; no

such fact can have both, or neither. Judgment, that is, cognition expressible by a proposition, is knowledge explicit, evolved, complete: in the proposition something is affirmed or denied of something. Apprehension, that is, cognition expressible by a term, is knowledge implied, unevolved, incomplete: in the term there is neither affirmation nor denial. Yet the idea denoted by the term implies or involves judgment antecedent, while it may also be a step towards judgment consequent. When the names Apprehension and Judgment are used in these logical meanings, it might seem at first sight as if the difference between the mental facts which they denote were purely subjective: we might believe that our knowledge of any object whatever may take indifferently either the one form or the other. Closer scrutiny removes this impression. Mental affirmations, guarded by the relative denials, lie at the root of all cognition; and this is saying, in other words, that all knowledge takes its rise in the form of Judgment.

Accordingly, this formal distinction affects the next widest of the distinctions between modes of cognition, that which separates Knowledge Immediate from Knowledge Mediate. The former is the root of all our knowledge; the latter grows out of it. In the former, the only object known is something which is present, and which is the immediate object of our consciousness; in the latter, this immediate object represents another object, which is remote, not present, but which is known through the medium of the first. Between those two kinds of knowledge there is a formal difference. Every fact of Knowledge Immediate—every fact in which consciousness gives us knowledge of a present object, and does not rest in that confused state which is really no more than feeling,—must have the form of Judgment; neither the complex fact as a whole, nor any of its constitutive elements, can be thought otherwise than as a mental affirmation or denial. Knowledge Mediate, on the contrary, may have either form; the alternative, however, being determined by the circumstances. Judgment, as being knowledge complete and explicit, is the form which mediate knowledge takes when it is contemplated as being a *result*, as that for the sake of which antecedent processes were instituted; while Apprehension, as being knowledge implied, and therefore more quickly thinkable, is the natural form of knowledge which is contemplated as only a *step* towards something beyond it, whether that be a further cognition or a fact belonging to some other mode. These considerations dictate, as convenient if not perfectly exact, a distribution of cognitions; in which knowledge immediate may be considered exclusively under the form of judgment, while knowledge mediate must be considered under both forms.

I. Our Immediate Cognitions, those intuitive beliefs on which the whole structure of human knowledge is built up, are of Individual objects only. This cardinal doctrine being premised, all those deeper questions that lie under it are for us unimportant. Nevertheless some of them must be answered in outline, if it were only that we may be put in possession of names for mental laws which must afterwards be referred to.

Our immediate knowledge, then, is constituted, in every possible instance, by elements of two kinds. We know objects, not absolutely, but under conditions or relations. We have knowledge *à posteriori*,—that is, gained through experience, a knowledge vast and always becoming wider; but this knowledge is limited by a few fixed cognitions *à priori*, necessary, as being independent of experience, and constituting the laws or conditions of all *à posteriori* knowledge, whether immediate or mediate. The individual objects of our immediate knowledge must be either corporeal objects, or internal phenomena of the subject-mind; but our knowledge of objects of either kind is not possible without the concurrence of cognitive elements be-

Data for
Theories of
Literature
and Art.

Data for
Theories of
Literature
and Art.

longing to both classes, *à priori* and *à posteriori*. The individual object is given to us by experience; that is, in a cognition *à posteriori*: the laws under which only we can know it are indeed incapable of operating unless in relation to an object so given; but they are native, mental, *à priori* laws. The frequent necessity for considering separately the two several kinds of elements, gives rise to a division of names. Accordingly, our Immediate *à posteriori* knowledge of corporeal objects has been called Perception, External Perception, or Perceptive Consciousness; our Immediate *à posteriori* knowledge of internal objects, phenomena purely subjective to the ego, has been called Internal Perception, or Self-Consciousness: and Hamilton has generalized the two kinds by referring both to his Presentative Faculty. Our latent but inevitably evolvable cognition of the *à priori* conditions of consciousness, whether internal or perceptive, has been denoted by being referred to an original power receiving different names; as Reason from Kant and most others; Common Sense (awkwardly) from Reid; the Regulative Faculty from Hamilton.—But this abstractive separation of the two correlative elements must not blind us to the essential indivisibility of the fact. Every individual fact, which we could cite as an instance either of Perception or Self-Consciousness, is really a fact of perception or of self-consciousness conditioned by the regulative laws of reason.

II. All the limitations of both kinds, which are imposed on our immediate knowledge, necessarily continue to hem in that knowledge, when, by becoming Mediate, it is developed and made practically useful.

Its capability of becoming mediate is founded on two mental laws.—*First*, The mind has that power of Retention or Conservation, which was noticed as standing in relation to consciousness at large. It can retain, out of consciousness, all mental phenomena which it has experienced, to whatever mental mode these may belong; it can retain alike a feeling, a cognition, a wish, a volition. *Secondly*, The mind has, within certain limits, the power of Reproduction. Past facts of consciousness, retained out of consciousness, may come into consciousness again; and, on being thus reproduced or represented, the past facts become objects of new facts of consciousness. These new facts must be specifically facts of cognition; wherefore their specific laws are here most aptly in place.

(I.) A new cognition, if it is thought of as the *result* of a process of mediate knowledge, must take the form of Judgment,—of knowledge explicit, mental affirmation or denial. The process is one of comparison; the judgments may be distinguished from judgments intuitive, by being called Comparative; and the theory of them, while for most of our practical uses it is grounded firmly enough on common sense, is systematically evolved in the science of Logic. The formation of comparative judgments is the result which we shall have to consider as aimed at in the processes to be theoretically described as Exposition and Persuasion.

In regard to the objective varieties of comparative judgments, we are interested only in marking the progress by which, beginning with application to individual objects, they rise to embrace classes of objects.—All the compared objects may be Individuals, each of which was formerly known by us in a fact of immediate consciousness, and is now represented. This is the only case in which the resulting judgment can be the first comparative judgment which the process contains. All other cases presuppose other comparative judgments, and therefore require a more severe exertion of mind. The presuppositions become more numerous, and the mental strain grows more intense, with every new introduction of a compared object which is not an individual but a Class. For a common term, which is the name of a class, and is necessary for our compendious thinking of

Data for
Theories of
Literature
and Art.

that class, is merely an abbreviated definition of the class, which is itself a proposition, the expression of a judgment. Such a judgment has been gained through the process called Generalization; that is, a judgment, or series of judgments, in which given individual objects are compared, and formed into a class in respect of similar attributes; or in which, after the same manner, given classes are combined into classes more extensive. In the process of Specification this procedure is exactly reversed.

(II.) The last assertions in this cursory review of comparative judgments have already led us into one section of the doctrine previously propounded, that Apprehension is the natural form of mediate cognitions, which are only steps in processes leading to something beyond.

A term, which is the expression of a fact of Apprehension, must belong to the one or the other of two kinds. It may be a Singular Term, the name of an Individual; the name of an object, which may or may not be actually divisible into several component objects, but which is thought of from a point of view in which it is one object only. A term, again, may be a Common Term, the name of a Class; and, as above hinted, this class may be constituted either by individual objects, or by narrower classes. Now, the name Apprehension being conveniently confined to knowledge that is mediate, as being of objects not present, the distribution of apprehension into kinds runs parallel to the distinction between terms singular and terms common. The name Imagination belongs rightfully to all apprehension of objects individual: the name Conception is fitly restricted to the apprehension of universals; that is, of the ideas denoted by common terms. The words Image and Concept signify severally the two kinds of facts as regarded from the objective side.

1. Imagination is always Reproduction. It gives, as objects of immediate cognition, mental states identical in constitution with, and therefore accepted as representing, facts of past consciousness, or factors or elements of such facts. But it has two phases, differing directly in respect of their antecedents, and hence deriving a difference in respect of the remote objects which they represent. In the first of these the remote object may be said to be the Past; in the second, it may be said to be the Possible.

(1.) In the first case, the mind represents only one individual fact of past consciousness; and, it may be noted, the representation is probably never complete. Here Imagination is Simply Reproductive.

This phase of imagination is governed, and the second through it, by the great mental law usually called the Law of Suggestion, or the Association of Ideas. The most authoritative systematization of this law is Hamilton's. All phenomena of the same subject-mind are capable of suggesting each other; a mental fact given in present consciousness may suggest any other, which was formerly in consciousness and has been retained. The suggestive power is primarily given to mental facts either by their identity of constitution, or by their original coexistence or coadjacency in time. On the one hand, a present mental fact may suggest any past fact constituted wholly or partly by the same factors; on the other hand, a present mental fact may suggest any fact which was formerly present with it in consciousness at the same time, or as a step in the same mental process. The suggestive power is modified, or secondarily determined, by this law: that mental facts are suggestible in proportion to their "interest" for the subject-mind; that is, in proportion to their tendency to excite emotion. Out of these widest laws, primary and secondary, arise others more specific and complex: and all of these might, for use, be combined into the one doctrine; that the phenomena of the same mind suggest each other through Resemblance, Contrariety (which implies resemblance) or Contiguity.

Data for
Theories of
Literature
and Art.

Again, reproduction may be influenced by Will, though not directly yet powerfully. A complex thought or a group of thoughts being present, we can will to concentrate consciousness on some one factor or member of it. The case exemplifies the process called Attention (or Abstractive Attention), which will be examined immediately; and the thought thus attended to may and will suggest others, which, though related to it either by constitution or in time, had been overlooked when it was contemplated only with others.

Lastly, a past thought or other fact may be reproduced, without our knowing that we had it before. We may even believe that it is a new combination, produced by a process issuing in imagination of the second and higher phase. But this step may be followed by another, in which we recognise the past fact, that is, know that the new fact represents a certain past fact. There is thus performed a process which, beginning with Retention out of consciousness, proceeds in consciousness to the successive steps of Reproduction and Recognition. When the process has thus been completed, we say, not that we have imagined the past fact, but that we have remembered it; and it would be convenient if the name Memory could be applied, for technical uses, to such a process as a whole. It is, however, very frequently used to designate only one or another of the constitutive steps. It is particularly to be observed, that the reproduced thought is truly and essentially an Image; that, indeed, this reproduction of some one past fact, in whole or in part, is the normal and radical instance of Imagination. But till recognition has taken place, the reproduction is virtually for us equivalent to imagination not of the past, but of the possible. Therefore, and because it is on our thinking of the possible that the laws of imagination have the closest practical hold, the name imagination comes to be seldom applied to simple reproduction.

(2.) In short, the name is very usually, and with little of immediate harm, limited to that higher phase of imagination, whose remote object is something which we can think as possible, something whose individual existence we can suppose without violation of any law of thought. Imagination of this character has been called Productive, and (less safely) Creative. The antecedent process to which its peculiarities are owing, would be indicated if we were to call it Synthetic. It does not represent merely one past fact or part of such: it represents two or more past facts, or factors of such, combined under some relation which gives to the combination an individual totality or unity. Consequently it is the result of an antecedent process, which never can have been very simple, and may have been overwhelmingly complex. It must have embraced, besides modifying and colouring flashes of emotion, two or more distinguishable stages of cognition. First, more images than one must have arisen in the mind, through acts, more than one, of simple reproduction. Secondly, There must have taken place judgments, in which there are compared together, in respect of their mutual relations, either those images as wholes, or factors or features of each, or the wholes of some and parts of others. On these antecedents follows the synthetic formation of the new image, an image of something which as a whole had not been known or thought of before. In short, imagination simply reproductive gains its image from one retained fact of past consciousness; imagination productive or synthetic,—imagination in the common meaning,—sometimes and aptly called Fantasy,—gains its image from two or more facts of simple reproduction followed by a series of comparisons.

The function of synthetic imagination cannot be examined too closely by the student either of eloquence or of poetry.

2. The remote object of Conception may be said to be

the Universal. A concept, the idea of a class, denotable by a common term, is really, as already asserted, an abbreviated and implied judgment, which would have been explicitly denoted by a definition of the class. Further, this implication, so necessary for rapid and easy thinking, cannot be reached otherwise than indirectly; the concept can be thought only symbolically, as through words, arbitrary symbols. These are adequate reasons, both for the greater mental exertion required in the fact of conception, and for the difficulty of harmonising conception with imagination. A common term does not directly suggest an image. It does, indeed, tend to fall back into the image, through the desire of the mind, in thinking of classes, to make its intellection clearer through thought of the constitutive individuals. But the thought which it directly suggests is the implied judgment; it raises the question of truth or falsehood, which the thought suggested by an image does not. The mood of mind excited by concepts,—that is, specially, the tone of feeling,—tends to weaken or destroy the mood excited by images: and both this tendency, and the comparative inefficacy of concepts to excite images even indirectly, increase with the distance of the concept from immediate cognition; or, in other words, with the increasing width of the classes which the concepts represent. All these considerations are rhetorically very important.

12. The reason for adopting the term *Wishing*, to denote the "Active Principles" or "Powers" of Stewart and other standard writers, was virtually assigned in the hint, that wishes are of two kinds, *Desire* and *Aversion*. The received theories confine attention to the former, the positive form, neglecting the latter, the negative. Each implies the other; and, though it is desire that is by far most frequently the direct prompter of volition and consequent action, yet it is a question of circumstances whether it may not be by aversion that this function shall be discharged. The theory is not complete unless both forms be taken account of.

All wishes, as developed in the positive form, are referable to one or another of the three kinds described by Stewart as *Appetites*, *Desires* (in a narrow sense of that word), and *Affections*. It is only with the latter two of those classes that rhetorical inquiries are concerned; and, for these or all the three, Stewart's doctrine might serve our present uses reasonably well, if there were worked into it the few points that bear directly on aversions. But, even for studies such as ours, increased clearness of apprehension may perhaps be won through an analysis somewhat closer.

In the first place, all wishes are distinguishable objectively into *Two Orders*. The first order contains Stewart's *Appetites* and *Desires*, with the relative *Aversions*. These may be described as *Wishes Simple* or *Direct*; and there lies on the surface a reason for calling them *Self-Regarding*. The second and higher order contains Stewart's *Affections*. These may similarly be called *Wishes Complex* or *Indirect*; and they may be spoken of also as *Not-Self-Regarding* or as *Sympathetic*.

The analysis of wishes belonging to the first order will open the way for the analysis of those belonging to the second. But there may be prefixed a notice, that exception is to be taken to the answer most commonly given to the question, what is the object of a wish? According to Stewart, the objects of appetites and desires are things, and things of different kinds; the objects (proper) of his affections are persons. More exact inspection, it is thought, entitles us to say, that all the objects of wishing are primarily of one and the same kind, the differences between them going no further than modification.

I. The true object of a wish must be something, by the existence of which the wish would be exhausted.—First, then, the object of a *Simple* or *Direct* wish is in every conceivable case a state of the subject-mind, the mind that

Data for
Theories of
Literature
and Art.

Data for
Theories of
Literature
and Art.

wishes. Secondly, that state is a feeling, either emotion or sensation; or it is a state in which, if it be thought of as complex or continuous, feeling is thought of as the predominating element. The object of a desire is a state of pleasure; the object of an aversion is a state of pain. Thirdly, this state is thought of as future; futurity is implied even in the desire of, or aversion to, the continuance of a mental state which has already come into existence. Fourthly, this future state of pleasure or pain of the subject-mind must have been represented by the subject in an antecedent fact of imagination; and, by reason of the nature of the object, this fact must have been specifically one of Imagination Synthetic.—Through these features of the object, this order of wishes is distributable into two classes. The Appetites, and the relative aversions or loathings, are Sensuous Wishes; the feeling imagined is a state of sensation. The Desires of Stewart (Propensities of other authors) and their contraries, are wishes Non-Sensuous; the feeling imagined is a state of emotion.

The elements which have been described are all the elements which are absolutely essential to the object of a direct or simple wish. But there is yet another element which, though inessential, is seldom if ever absent, and which in our everyday thinking receives more attention than the others. We think of the object, our own future state of feeling, in relation to something which has a tendency to bring it into existence; something which is a cause or a constituent of a cause, of which the mental state we desire or are averse from is imagined as the effect. In unanalytic consciousness the idea of this cause or con-cause usually obtrudes itself so as to obscure,—and may often come up so strongly as almost quite to conceal,—all the other constitutive ideas. It has this prominence for two sufficient reasons. In the first place, it is only when the idea of a cause is incorporated into the idea of the object that a wish becomes definite, precise, clear; without that idea it remains vague, shadowy, describable perhaps as a longing—a longing for something we know not what. In the second place, and consequently, until the idea of a cause has arisen there is no outlet towards volition; not only is volition subjectively impossible, but there cannot even arise the question, whether the object of the wish is attainable.

It is a truth not to be overlooked, that, if this analysis be correct, that idea of the object, out of which a direct wish emerges, and towards which it tends, has inevitably a character, not only of complexity, but also of greater or less indistinctness and vacillation. This is in perfect harmony with the character of wishing in itself, and with the function which it discharges as a step in mental processes. Its own character inclines towards indistinctness, in proportion to the approach it makes to the subjectivity of feeling: its transitive function, as mediating between cognition and volition, compels it to vacillate, and even to relax its hold on the central point of the idea, in proportion to the closeness of its reference to action. The ultimate reference to self, and to a state of feeling of which self is the subject, can never be lost entirely in consciousness without disappearance of the character of the fact as a wish: but this reference is naturally and irresistibly forced into the background by the necessity of giving prominence to the cause, through which lies the only path to action.

These considerations go far to account for the prevalent opinion as to the objects of the facts which we commonly describe as appetite and desire. They may be said, indeed, to justify our using, in description of the object of such a wish, forms of expression implying no analysis going deeper than the datum of unreflective consciousness; and convenience and clearness concur in driving us on such expressions. But the result of the more accurate dissection must not thus be allowed to slip out of view; and opportunities may often occur for appealing to it.

and Art.

II. In regard to the Affections (of Stewart) the first and chief doctrine to be asserted is this.—All the four characteristics of the objects of Simple wishes belong also to the objects of these wishes, the Complex: the description is correct for these as for those. It must be maintained, without qualification, that the true object of an affection, benevolent or malevolent, is a mental state of the subject, not of any other person or persons. The seeming paradox requires to be justified.—The description of the object, complete for simple wishes, is not complete for wishes that are complex. The object of a wish belonging to this order has two characteristics in addition to the four. First, the idea of cause, inessential to the object of the lower order of wishes, becomes essential here. Secondly, this cause must be a mental state, and specifically a feeling, pleasant or painful, sensation or emotion, of some conscious and sensitive being or beings different from the subject. How, then, do we account for the prominence which, in our consciousness of an affection, is unquestionably held by the idea of the person we commonly speak of as the object? It is accounted for on the same principle as the corresponding difficulty in the former case; but here the answer is even easier. The idea of cause, and of a state of the person loved or disliked as being the cause, cannot but come up in a wish of this character: the wish is not possible without it. It is, further, the state of that person, not our own state, that will be directly affected by the subsequent volition. Therefore our consciousness is ruled over, or even monopolized, by the thought of that person and of the state in which our volition will place him.—To all conceivable objections, again, there is this reply. An affection of mine would not be exhausted by the pleasure or pain, the happiness or misery, of the person to whom I wish well or ill: it could not be exhausted till I should come to know that state of his, and to experience the correspondent emotion. Yet here, as in the other case, our phraseology is conveniently modelled on the unanalytic view; the more correct doctrine being reserved for use when the other threatens to lead astray.

Nor does the doctrine really raise any ethical difficulties. The moral relations of the affections, indeed, do not come out clearly, until distinct account is thus taken of the subjective reference made in the last resort by all of them. It is only thus that we recognise precisely the functions of the two great laws, which govern affections and the consequent volitions and actions.—The law of Sympathy originates the pleasure which attends our imagination of the pleasure or pain of others, the pain which attends our imagination of their pain or misery. The law of Duty, a higher law, the highest of all laws,—the law in virtue of which we have pleasure in the thought of that which is right, and pain in the thought of that which is wrong,—discharges, in regard to the affections, a double function. It intensifies and sublimates the sympathetic pleasure which is concomitant on goodwill to our fellow-men: and, when there has been excited the pleasure incident to ill-will, it supplies the place of the sympathetic check, and opens the mind to new images suggestive of worthy emotions. Sympathy is actually pleasant; a good conscience is actually pleasant: both of these truths are laws in our nature; and woe to us if our nature were not so ruled! Nor is this a resolution of affection into selfishness. Small risk does that man incur of undue regard to self, whose unhappiness is greatest, not in remembering disappointment of his own desires, but in witnessing the miseries of others; the man who has learned to find his highest happiness, not in the nourishment or gratification of wishes which do not pass beyond himself, but in the sympathetic contemplation of the wellbeing of others, and in the conscientious wish to promote their happiness or alleviate their suffering.

It is further to be noticed that, when the object of wishes has been identified correctly, the question whether

Data for
Theories of
Literature
and Art.

an Affection is a desire or an aversion is seen to be quite different from the question, whether it is Benevolent or Malevolent. Good-will and ill-will may alike, according to circumstances, develop themselves in either form. In being conscious of a benevolent affection, I may either desire for the person thought of a state describable as pleasure or happiness; or I may be averse to his being the subject of a state of pain or misery. In being conscious of a malevolent affection my position is alternative in the opposite way.

The laws
of volition
—the ante-
cedents of
action.

13. In regard to Willing, we are here bound chiefly to keep in sight the real and radical distinctions which separate a volition from the antecedent wish.

They are different even when regarded subjectively, or as states of mind. Indeed, though a volition must be preceded by a wish, there are wishes which though they might be succeeded by volition are not so; and there are wishes which cannot be so succeeded. This is a point which will by-and-by be put to special use.

Again, wishing and willing must be both different in character, and non-concurrent in time, in respect of the difference of their objects, and the relations in which the objects stand to each other. This distinction is clear even on the common view as to the objects of wishing: it emerges with added strength of evidence on the more analytic view of the character of those objects. In a given process embracing both mental facts, the two objects are regarded by us in a light which pre-supposes both their non-identity, and the difference between the wish and the volition. While we still look forward to the consequent action as future, we consider the object of the wish as an end or purpose, the object of the volition as a means towards that end: during and after performance of the action, the object of the volition is for us a cause, the object of the wish is the relative effect. The distinction is obvious as to Simple Wishes. It holds also as to Wishes Complex: for though the idea of a cause is there necessary, it is only the idea of a cause intervening between the object of the wish and that cause which is the object of the volition.

The object of a volition, that which I will, is a fact, either of my own mind or of my own body, which I know or believe myself to have the power of bringing into existence; and I will it because I know or believe it to be a cause, or one of the elements making up a cause, either adequate to produce as its effect the state of feeling which had been the object of an antecedent desire, or adequate to avert the state which had been the object of an antecedent aversion. The object of a volition is, in one word, an Action: a fact consequent on volition is the only kind of fact to which the name of action is strictly and properly applicable.

Further, as the object of a wish must have been imagined antecedently, so must it have been with the object of a volition. We cannot but know what we will; and the nature of the case precludes cognition in any other form than that of imagination. An image of the act must intervene between the wish and the resulting volition. In the volitional stage, as in the preceding, the rapidity of the process may doubtless be so great that the two successive facts shall not at the time be distinguishable from each other: but their real consecution and difference must not be lost sight of. The circumstance produces a complication which should be noted by the student of eloquence.

The process may, and with effects not less important rhetorically, be complicated still further by the intervention of processes of Deliberation. This name indicates a series of comparative judgments: the things compared are two or more judgments inconsistent with each other; and, if the progress towards action is not broken off, the issue must be a judgment accepting one of them as true to the

rejection of the others. We may and do deliberate as to both of the objects,—as to the object of the wish and as to the object of the volition,—as to the end, and as to the means: and hence the imagining of each of the two successive objects may be preceded, delayed, and conditioned by an elaborate series of inferences.

14. In the psychological outline now closed, there has in effect been anticipated the theory of Persuasion; that is, the section of Rhetoric which is at once the most thorough and the most extensively available for use.

Bearings of
the psycho-
logical laws
on persua-
sion—the
character
of atten-
tion.

For, in performing completely the process called persuasion, what we aim at is the generation of volition in the minds of other men; and there have come up before us here, one after another, all the steps of the process which issues in volition, that is, of the process which, in persuasion, we seek to originate in the minds of others. In the simplest view that is even conceivable, that process involves the following successive steps (feeling being in the meantime overlooked): a fact of imagination synthetic, yielding an image of the object of the wish; a fact of wishing, in the form either of desire or of aversion; and lastly, the resulting fact of volition. If, however, a dissection attempted in the last section be sound, the process must always be less simple. There must first be imagination and consequent wish, referable to the object which we are desirous of or averse from for its own sake as end. There must next be imagination, referable to that action of our own which is regarded as a means towards the satisfaction of the first wish; and only out of this second image can the volition arise. Feeling, however,—and, specifically, emotion,—pleasure or pain, really (as we must hold) accompanying each of those steps, will necessarily, at some stage or other, and probably more than once, emerge into an evanescent prominence, and for a moment intervene between the facts which are distinctively objective.

It was hinted, however, that rhetorical rules cannot grasp closely any but the first two of the steps thus described:—the Image and the subsequently emergent Emotion. It must likewise be kept in mind that, as also hinted, these two steps are common to eloquence and to poetry. Eloquence aims at continuing the process to its consummation. Pure poetry aims at turning the process back on its first step; and it is a question to be raised hereafter, on account of its bearing on rhetorical points, what effect is produced when poetry does aim at proceeding further.

There has to be added one other doctrine, which could not be explained satisfactorily till all our materials were accumulated. The problem regards the influence of will on cognition or intellect; and it is raised by this question:—what is the real nature of that mental state, which we seem to know so familiarly under the name of Attention.

Attention might be said to be the concentration of consciousness on certain objects. It is plain that attention is often the result of volition: the knotty question is, whether it is always so? It may be that those are right, who hold that an instinctive concentration of thought, an attention not determined by will, is a necessary condition of all consciousness: but it is not easy to see one's way through the difficulties which stand between us and that conclusion. At present it is enough to make this assertion:—that Attention strictly so called, a concentration of thought determined by will, is an indispensable condition of the rise of consciousness above that confused state, of which feeling is the norm. A fact of attention, in this sense of the word, is a mental process, consequent on volition and its antecedents: it must either be constituted exclusively by cognitive facts, or have cognition as its first and determining step; and lastly, it must involve what is usually called Abstraction, or the throwing certain objects out of conscious-

Processes constituting Eloquence. ness and retaining others. Attention, then, and attention which is voluntary and abstractive, is an antecedent and peremptory condition of all cognition that is "clear" (in Leibnitz's sense of the word); and such cognition must precede all further progress of thought that is available for any practical purpose whatever.

Accordingly every fact of clear cognition is properly an action: it is a voluntary exertion of mental energy, having had for its antecedent a process in which we have run up the whole gamut of mental manifestation. In the sense thus indicated, it may justly be alleged, of any mind exercising even the lowest degree of available intelligence, that

it is always active. A mind must act, that is, its phenomena must be directly consequent on its own volitions, if it is to rise above the level of a dreaming idiocy.

For our use here, this doctrine of attention supplies invaluable corollaries. If the doctrine is accepted (and it does appear to be almost a truism), the process by which volition may be excited, is perceived to have a field infinitely wider than that which at first it might seem to cover. The theory bears directly, not on persuasion only, but on the attempt to generate pure belief; and its applications, not confined to eloquence, range far and sink deep in the realm of poetry.

Processes constituting Eloquence.

III. ANALYSIS OF THE PROCESSES CONSTITUTING THE ART OF ELOQUENCE.

The character and relations of the processes of communication through language.

15. When we seek to identify those normal and elementary forms, into which all literary processes must be resolvable, we might perhaps expect to find those forms naturally determined by the characteristic differences of the three purposes, with a distinctive view to one or another of which communication must always be made. But the first of those purposes, the generation of belief or judgment, is entertained in so many dissimilar shapes, and aimed at from data so exceedingly various, that absolute similarity, even in prominent features, is not to be looked for in all the processes leading towards it. In recognising two distinguishable kinds of processes, as each tending towards this end, we accept the smallest number of distinctions that can yield any clearness of doctrine.

While, therefore, the Purposes of communication by language are only Three, the Processes relative (within that sphere) to the attainment of these purposes must be set down as Four.

First, The name of Exposition will here denote all processes, in which the generation of belief or explicit knowledge is aimed at through any means other than argument.

Secondly, The name of Argumentation will suggest, at once, processes in which, the generation of belief or explicit knowledge being the purpose, the means used is argument or proof.

Thirdly, The name of Persuasion is applied by common consent to all processes, in which the end aimed at is the generation of volition.

Fourthly, The name of Poetical Representation may indicate all processes, in which language is used for the generation of pleasure through imagination.

The substance of the Theory of Eloquence consists in the analysis of the first three of those four processes; and these will next be taken in the order in which they have been named: which order, likewise, as noted before (section 2), is that in which they occur when all of them are completely incorporated into one discourse. In the same section those weaknesses were touched on, which attach to the theories of exposition and argumentation, and which leave the theory of persuasion as the strong ground of a rhetorical system.

I. THE PROCESS OF EXPOSITION.

The character and varieties of the process of exposition.

16. In the cursory examination, which is all that this process requires, the first point is the setting aside of those cases where the generation of belief is dependent on the matter asserted, from those where it is dependent on the manner in which the assertion is made. Evidently it is only on cases of the latter kind that any firm hold can be caught, even by the very few rhetorical laws here obtainable.

I. Belief may be commanded, without proof, by the character of that which is asserted. It may be a truth self-evident to all men; and that either as being a universal

condition of human knowledge, or as being vouched so thoroughly by experience that it is admitted unhesitatingly as a practical rule of life. Or it may be something which, though not self-evident, is yet undoubtingly admitted by those to whom it is stated.

In neither of these varieties of the first case are rules properly rhetorical either needed or attainable. The task of the speaker or writer is, at the utmost, nothing more than that of reminding his hearers or readers of something which supposably ought to be brought distinctly to their remembrance. If anything else is requisite, it can only be explanation of the words used; and, in certain kinds of eloquence, much time is often bestowed on such explanation, involving not seldom much of argument. When the process is purely expository, the only qualifications required by the party communicating are two: clear thinking, clear and distinct apprehension of the objects treated; perspicuous language, that clearness of expression which does not necessarily attend clearness of thought, but towards which clearness of thought leads, and which, when thought is obscure, cannot be attained unless through a momentary accident.

II. Belief may be commanded, without proof, by the manner of communication. Belief may thus be commanded in either of two ways.

1. It may be generated by the aspect in which the assertion itself is made to appear. The alleged truth is so represented that the recipient wishes it to be true. This is really one of those complex cases, in which the several communicative processes are fused wholly or partially into each other. What is performed is, in fact, an incomplete process of persuasion: that process is carried on to the formation of the wish; and then the minds which are affected by it are led aside towards belief instead of being urged further onwards to volition. Things which we desire to believe are undoubtedly believed by us infinitely more readily than things to which we are averse, or about which we are indifferent; and a lively act of imagination, giving rise to an intense wish, is a step which, especially in minds untrained to the testing of evidence, stands close to positive belief, if only no circumstances are obtruded which make the fact in question to be impossible or highly improbable.

2. The belief may be generated by the aspect in which the speaker or writer is able to represent his own character and position. This variety of the process is the first of the three *lóres* explained in the Rhetoric of Aristotle. It is the method of generating belief which he describes as residing in the exhibited character of the speaker,—as taking effect when the discourse is so framed as to make the speaker appear worthy of credit.

In a word, the case is one in which the writer or speaker aims at taking the position of a witness; and, the discourse being assumed to supply the only means which the audience have of judging as to his character, he has to aim at exhibiting himself as possessing all the qualifications of a

Processes
constituting
Eloquence.

witness who is trustworthy. In one who gives judicial testimony, the essential qualifications are of two kinds, intellectual and moral; and these are the quarters on which the clearest light must be thrown by the discourse, when an orator or literary man strives to give to his words the weight of testimony. Which of the two is the more important, is a question of circumstances.

Clearly, in both respects, rules of art must be all but powerless. That which the man is, will essentially determine that which he can seem to be. The only field indeed in which forethought and art may raise seeming far above being, is not literature proper, framed for being pondered over in the closet, but oratory proper, designed for oral delivery. Just as a jury forms, from the manner in which a witness gives his evidence, an impression favourable to his intelligence and honesty; so may they, or any other audience, especially a large and mixed one, be impressed similarly towards a public speaker, by features of his manner, which are really the fruit of elaborate study and practice. The small literary efficiency of this means of impressing belief has almost banished it from notice in modern works on rhetoric; although its admirable oratorical power, especially in the shape of skill in elocution, commended it naturally to Aristotle, whose precepts had their chief practical end in the instruction of public speakers. Weak, however, as rhetorical theory is here, the points deserve to be paused over for a moment.

(1.) In regard to the moral qualification, in its bearing on communication strictly literary, very little can be elicited with advantage. A literary man is presumably an honest witness, ready to report his knowledge conscientiously and correctly. He can hardly exhibit himself in any other light, unless by betraying innate moral weakness or depravity. Yet literary statements affect us strongly, both with prepossession and with prejudice, even when the moral elevation or sinking is not very decided, or when the difference extends no further than to disposition or temper. There is all the unlikeness in the world between the distrust with which we learn to treat the assertions of the savage and gloomy Swift, and the kindly confidence we repose in what is said by the cheerful and kindly Addison; nor does the sympathetic glow which is shed over us by the genial Goldsmith accompany us when our teaching is derived from the honest but arrogant Johnson.

(2.) The intellectual position of the writer must be established both as to opportunities, as to intelligence, and as to knowledge. But, first, ostentation either of intellectual power or of resulting knowledge would be a violation of the first section of the rule, as tending to excite moral distrust; and parade of ability or skill of any kind, by calling away attention from the matter to admiration of the writer, would cool the tendency to faith, even if its moral effect were not directly adverse.

In the creation of impressions favourable to the intellectual character of the writer, the cast of his style is of great importance; although here, as in regard to most points affecting language, little more can usefully be done than the calling of attention to the principle. In Bentham's posthumous essay on Language, an attempt is made to generalize this doctrine. Intellectual strength, it is said, is indicated by a character of style which may be called Dignity or Self-possession. It has the effect of indicating the writer's mastery both over himself and over his matter. It is distinguishable through its want of certain faults, especially two: *first*, laxity, a general prevalence of offences against perspicuity in the use of words; and *secondly*, a tendency to grope about among ideas without at once finding the right one, out of which arises a superfluity of ideas as well as of words.

(3.) To those two essential qualifications of the witness, Aristotle adds, for the orator, a third, Good-will towards

those whom he wishes to impress with belief. For oratory dealing with party-questions, the production of a favourable impression in this direction is clearly of great moment. In literature the circumstances give but seldom occasion for raising such questions. But in some kinds of literary compositions,—as, for instance, History,—there is continual occasion both for watching the means of fairly causing such impressions, and for guarding against the distrust which may spring up where the adverse inclination of the writer is not or ought not to be concealed. When, before canvassing proofs, we do distrust an historical statement bearing on a party-question, our want of faith in the historian as adverse to our own opinions is almost always complicated by distrust in the assertion itself, as one which we are unwilling to believe.

Perhaps it is scarcely worth while to add, that the same favourable impression, which may generate without proof a belief that otherwise would have been totally absent, must, *à fortiori*, be efficacious in facilitating belief, in cases where proof is offered but is not in itself sufficient.

Processes
constituting
Eloquence.

II. THE PROCESS OF ARGUMENTATION.

(I.) THE CHARACTER OF ITS RHETORICAL THEORY.

17. This process must by us be studied for a purpose which may become the clearer, if we first contrast it with another purpose, for which also it is analysed by a science having a primary and preferable hold on it. The logical problem and the rhetorical.

As a process of thought, Argumentation is subject to Logical Laws: as a process of communicated thought, it is subject to Rhetorical Laws. The process which we review, being the process in which argumentative thought is communicated, is not completely theorised unless, while its rhetorical laws are directly laid down, its logical laws are presupposed. The complete theory may be said to comprehend the solutions of two several problems.

The first is the Logical problem. It may be expressed thus. Given certain propositions as premises: it is required to determine whether any conclusion, and what conclusion if any, may validly be inferred from them.—The second problem, the Rhetorical, is not enounced so easily, in a shape at once sufficiently precise and sufficiently comprehensive. The following may be taken as a fair exposition of it. Given a certain proposition as a conclusion: it is required to determine through what premises, and through what use of those premises, the truth of the given conclusion may be made evident to persons who would not otherwise believe it.

The contrariety between the two problems should be marked from several aspects.

The solution of the logical problem enables us to *test* arguments: we take our stand on the data, the first two steps in the argumentative process; and we find the conclusion, the third step, or pronounce it impossible. The solution is exact, exhaustive, and peremptory; and it bears directly on the instance given.—The solution of the rhetorical problem is designed for enabling us to perform the more difficult task of *constructing* arguments, and of constructing them so that they shall be effective on other minds than our own. We take our stand on the conclusion, the third step in the argumentative process; and we seek the premises, the first and second steps, that these may be adduced in proof of the conclusion. The solution of the problem is approximate, incomplete, and probable instead of being peremptory; and accordingly its use extends no further than this, that it suggests to us the outline of a method, by the wise use of which (besides collateral advantages), the finding of premises to prove given conclusions may be made easier than it would be if it were set about without the use of any method guided by law.

Processes
constitut-
ing Elo-
quence.

That, accordingly, in which we are aided by this section of rhetoric, is first of all the Finding or Discovery of Premises, the other aids being consequent and dependent on this. It might be called likewise, in logical phrase, the Finding of Middle Terms, or media of proof: for what must be gained, in the first instance, is a term with which we might successively compare each of the terms of our given conclusion; and this term, the middle, being once discovered, the construction of the premises with it and the two others is a matter of course.

We express really the same analysis, but in a more familiar shape, if we say that this essential part of the rhetorical theory of argumentation aids us in the Finding of Arguments. For the word "Argument," strictly meaning the middle term, signifies very often, in common speech, the assumed facts on which a conclusion is rested, and often also the whole argumentative process.

Names of similar import described, among the classical rhetoricians, this dialectical or semi-dialectical section of rhetoric. It was the *ἔκθεσις* of the Greeks, the "Inventio" of the Romans and schoolmen. What it dealt with was called the Invention of Arguments in our own older language, when the distinction was not yet taken precisely between invention and discovery.

(II.) THE CLASSIFICATION OF ARGUMENTS.

Compari-
son of
schemes.

18. In most of our modern systems of Rhetoric, the theory of argumentation is a dead blank. Either an appeal is taken to Logic as the only science which can give any aid to the process; or else we are told that both the one science and the other are useless, and that the only guides to be relied on are knowledge of the matter, and practised sagacity, and sound sense.

The elaborate and special topical systems of the old world have not been, and are not likely to be, recalled into life by any one. But of systems of universal topics, intended to cover all departments of knowledge likely to be argued about, without descending into the details of any, there are more than one that have exhibited much acuteness and ingenuity. Among those which, while they have available points, are palpably deficient in generalization, Priestley's may be cited, for the sake of some features of likeness which will come to light immediately. All arguments, says he, are founded on one or another of *nine* relations. We must argue from premises which express one or another of these things:—Definitions; Adjuncts; Antecedents; Consequents; Means; Analogy; Contrariety; Example; Authority.

It may be observed, likewise, that there is one recent scheme of relations, which, though not applied by its author to rhetorical use, might be so applied without much difficulty; while it is not only, as might be expected, highly philosophical in conception, but also much closer than Priestley's to the scheme immediately to be explained. This is the doctrine as to the Import of Propositions laid down in Mill's Logic. All propositions, says Mr Mill, must import one or another of five things:—Existence; Co-existence; Sequence; Causation; Resemblance.

We attain a simplicity yet greater, without losing any principle that appears to be essential, when we recur to that universal classification of all possible arguments, which was expounded in the oldest and most celebrated of all extant rhetorical treatises, and has been elucidated with admirable effect in the best rhetorical work of our own time.

Aristotle, in his Rhetoric, distributes all arguments into *three* classes. His third class, the argument from *παράδειγμα*, or Example, is easily identified; but much darkness has rested on the question as to the nature and difference of each of his first and second kinds—the argument from *εἰκός*,

or Probability, and that from *σημείον*, or Sign. The only interpretation that is rational or self-consistent is one which is assigned by some of the commentators, such as Majoranus; and this reading, adopted by Archbishop Whately, may safely be believed to yield, as he alleges, the genuine classification of Aristotle.

According to Whately's scheme, the first kind of Argument is the *εἰκός* of Aristotle; the argument from Antecedent Probability, which is described and analysed as leading us from cause to effect. The second kind is Aristotle's *σημείον*; the argument from Sign or Symptom, declared to lead, not strictly from effect to cause, but from a symptom to the thing indicated by it. The third kind, Aristotle's *παράδειγμα*, is the argument from Example.

What is now to be given is an explanation of the Aristotelian scheme on this interpretation of it, and with much use of suggestions supplied by the interpreter. An attempt is made, however, to trace the rhetorical rules upwards to their principles.

19. In arguing or inferring, we pass from the known to the unknown; from something which is assumed as known already, to something which is not known till it has been inferred. Our inferred truth, the conclusion of our inference, must be one only: let it, for brevity, be called X. Our known truth, the datum, is likewise one in the aspect in which at first it naturally offers itself: let it be designated as A.

But, though the truths which are the matter of inference thus seem to be no more than two, the logical analysis, which shows them to be necessarily three (for the cases of immediate inference are reducible to the same principle which rules the syllogism), is vindicated even without the use of logical forms. From a known truth A, considered simply and by itself, an unknown truth X cannot possibly be inferred. We cannot from A infer X, unless on the assumption that there exists some *Relation* between them. This is our third truth, a second assumed truth:—that A and X are in some way or other mutually related. Even if we continue to express our reasoning in popular forms, we either make this second assumption silently, or incorporate it in the expression of our A. The assumption is made in this case as really and as thoroughly as it is made when, setting forth the inference in its developed logical shape, we exhibit the assumption explicitly as a second premise.

Taken strictly, then, the relation required is quite independent of all considerations derived from the uses to which it may be put. It is not strictly a relation even between the steps of the inference as such; still less is it a relation dependent on the forms the inference may take, or on the purposes to which it may be applied. It is a relation of matter, an objective relation: it is a relation between the objects which are the matter of the inference.

Hence comes the doctrine from which our classification of arguments must start.

I. From a known truth A we cannot infer an unknown truth X, unless in virtue of some objective Relation assumed to exist between A and X.

Accordingly, our classification of arguments ought to rest on a classification of the relations between all objects of thought. The construction of such a classification is a high and deep problem in ontology or metaphysics proper; and the experienced impossibility of reaching an exhaustive solution of it entails imperfection on our transformation of the solution into a practical shape. But it is not difficult to gain an approximate solution, which is exact enough for the application now needed.

Every thinkable relation of things must be placed by us in the one or the other of two classes.

First, it may be a relation direct, real, or purely objec-

ing Elo-
quence.

The prin-
ciples of a
rhetorical
system of
topics.

Processes
constitut-
ing Elo-
quence.

tive; that is, it may be a relation which we believe, rightly or wrongly, to subsist between the objects themselves individually. One of the widest of such relations is that of Causality. A may be a cause, and X the relative effect; or A may be an effect, and X the relative cause. But we have a generalization yet wider, and perhaps the very widest that is possible, in the relation of *Condition*. A condition of a thing is any thing but for which it would not be what it is: A may be the condition, X the thing conditioned, or contrariwise. Now our doctrine is this:—that all direct or purely objective relations are merely modifications of this one relation of Condition.

Secondly, the relation may be indirect, conceptual, or objecto-subjective; that is, it may be a relation which is thought, not as subsisting directly between the objects themselves, but as established between them indirectly, through our manner of thinking of them, or through the point of view from which we regard them. All these indirect relations, emergent through our own thinking, are resolvable into the one relation of *Resemblance*, which founds the process of classification. We think of A and X as being like each other; and, in respect of this likeness, we think of them as contained in one and the same class. Now, undoubtedly, in all real knowledge, the relation of Resemblance presupposes, and is no more than an imperfect evolution of, some real relation between the objects as conditioning and conditioned. But we are often able to discover a resemblance justifying classification, while we have as yet an imperfect apprehension of the real relation which is the root: and, besides this, the thinking of the relation under the form of resemblance between members of a class, gives us all the conveniences and advantages of general or universal reasoning, one especial advantage being the ability to shift our point of view. Therefore, as well as for special reasons which will immediately come to light, the relation of Resemblance actually lies at the foundation of our inferences much oftener than the more decisive relation of Condition.

Our classification of arguments, in fine, may rest on this theorem.

II. All those Relations of objects in virtue of which inference from A to X is possible, may practically be considered as resolvable into these two,—Condition and Resemblance.

Arguments, again, fall primarily into two classes, according as a relation of the one kind or of the other is that which is assumed.

III. All arguments are reducible to the one or the other of Two Classes. In arguments of the First Class, the relation between A and X is that of Condition; in arguments of the Second Class, the relation between A and X is that of Resemblance.

It cannot be noted too early, that these two classes of arguments differ signally in logical validity; not essentially, indeed, but in the uses they are practically put to. Arguments of the first class admit of being so framed as to be logically impregnable. Arguments of the second class, having data such as they always receive in practice, cannot be so framed as to escape from a logical fallacy. The point is marked by Aristotle. It rests on a principle having wide applications in philosophy; and the proof and illustration of it will appear when we reach particulars.

In the meantime, our classification must be carried down a step farther.

When the relation is that of Resemblance, the inference holds equally from A to X, and backward from X to A. Consequently arguments of the second class have no variation affecting the inferential character.

But when the relation is that of Condition, it is far from being a question indifferent, in which direction the inference is taken. An inference from a conditioning fact

to the fact which is conditioned, determined, or limited by it, is an inference very dissimilar in character to an inference the opposite way, from the conditioned fact to the fact which is its condition. Therefore arguments of the first class fall into two genera.

We have thus a final resolution of all arguments into Three Kinds, which correspond, substantially and in order, to Aristotle's three kinds as understood by Whately.

IV. The first class of arguments being distributable into two genera, the kinds of arguments which require separate analysis are three in all.—1. In arguments of the First Kind, A is a condition of X: we infer from condition to thing conditioned. The direction of the inference will be indicated if we describe these as *Arguments from Condition*. 2. In arguments of the Second Kind, A is conditioned by X: we infer from a thing conditioned to something which is a condition of it. The A being symptomatic of the X, these are aptly called *Arguments from Symptom*, or from Sign. 3. In arguments of the Third Kind, A and X resemble each other, and in respect of the point of resemblance are referred to the same class. These may be called *Arguments from Resemblance* or from *Classification*.

Each of these three kinds must now be examined more nearly.

1. The Argument from Condition.

20. The theory of this kind of argument may be drawn together in the five propositions following:—

I. If facts are known which are the sum or aggregate of all the conditions determining a fact unknown, the unknown fact may be inferred from these with positive certainty. It is possible, therefore, to gain through the argument from condition a conclusion which is demonstratively true. Cases in which the data may be said to possess this character, as embracing all the conditions which are immediate and liable to variation, are frequent in reasonings about the phenomena and events of the corporeal world.

II. If the known facts fall short, by even one, of making up the aggregate of all the conditions, the conclusion in which the unknown fact is inferred sinks to one degree or another of mere likelihood or probability. In reasonings about mental phenomena, involving human character and conduct, the data may be said to fall always short of the aggregate of conditions; and this is the kind of matter for dealing with which rhetorical rules are oftenest needed and most likely to be appealed to. Therefore, in practice, this kind of argument may be said to yield oftenest conclusions having only a higher or lower degree of probability.

III. When the aggregate of the conditions is not made up in the data, the degree of probability belonging to the conclusion depends much less on the proportional number of the conditions known, than on the character of them or some of them. The decisive question is, whether among the known conditions there be any which is describable (popularly rather than philosophically) as the cause of the fact dependent.

IV. If among the conditions of a dependent fact there be discoverable some one which seems to exert, while the others do not seem to exert, a positive power or efficiency in the production of the dependent fact, we consider this efficient condition as a cause, and the dependent fact as its effect. If the cause or efficient condition is known to exist, there arises a presumption for the existence of the effect; yielding a conclusion whose probability is proportional to the probability of concurrence of all the negative conditions, and is destroyed by evidence that any one of these negative conditions is wanting. If the cause is not known to exist, the existence of the effect is not made in the lowest degree probable, even by the known concurrence of all the negative conditions.

ing Elo-
quence.

The character and limits of the argument from condition—the relation of causality.

Processes
constituting
Eloquence.

V. This application of the idea of causality admits a specification referable to reasonings in regard to human character and conduct. If an act of will is one of the conditions of a fact, we hold this act of will to be the cause of the fact. If the act of will is known to have taken place, the occurrence of the consequent fact may be inferred with a probability, modifiable or destroyable by the known occurrence or non-occurrence of the other conditions. If the act of will is not known or presumed to have taken place, no probability of the occurrence of the consequent fact is raised even by the known concurrence of all the other conditions.

This kind of argument cannot be admitted to have been theorized broadly enough, till it is traced beyond the idea of cause into the higher idea of condition. The argument plainly has its root in the thought, that the concurrence of all the conditions of a fact must carry with it the fact which is dependent on them. Our specifying of certain conditions as causes is only an after-thought: it suggests itself to us as a limitation, under which we may still hold the inference together, when it falls asunder in the attempt to grasp it by the broader end.

That the thought of the causal relation is really inessential, is proved by the easy and effective use of the argument which may so often be made in reasonings about the phenomena of body, in regard to which we truly never do apprehend the causal nexus, becoming acquainted with laws only, that is, with conditions affecting classes of objects. Even in dealing with material objects, it is true, we are driven on the search after true causes, in every case where we are uncertain as to having been able to gather up all the circumstances on which depends a fact we wish to determine. But in doing so, we are beginning to tread on that boggy ground in which physical science has so often lost her footing. Our deductions begin to put on that character of uncertainty, which bedims more or less all our thinking about mental attributes and events.

When we rise fairly into this higher sphere, and endeavoured to infer what has been or will be the course of human actions, we see man's rationally determined will conflicting with other principles of his nature, and with the wills of his fellow-men, and with the obstacles interposed by things external and bodily; and we are driven from the field of demonstration, by the impossibility of knowing exactly all the secret facts out of which the complicated struggle springs. But we seize and cling to that which is our normal instance of causation, namely, the act of will. If that act can be proved, we know that the clue is in our hands; and the closer we can approach to the proof of it, the nearer is the moment when we shall walk confidently through the maze. Failing direct proof of the act of will, we seek proof of those actuating antecedents which we call motives; proof, that is, of desires or aversions which, naturally or probably or inevitably, would issue in volition.

Arguing from motives, indeed, is one of the most common instances of the uses to which this argument is put. Concomitant circumstances (the dealing with which would yield arguments of our second kind) raise the question, whether a man committed a certain act. The means of determination that will first be thought of by any of us is the discovery, whether he was or was not actuated by any wish which that act would have helped to gratify. If we cannot discover the pre-existence of some such desire or aversion, hardly any evidence short of actual observation will either induce us to believe in his commission of the act, or encourage us to hope that we should be able to convince others. But let there be given the wish, the motive: then the consequent volition, and the act in which it is exhausted, become at once facts which are more or less probable. Yet the complication and the doubt are not wiped away. The proved motive may be checked by motives

counteracting; the desire to kill or to rob may be stifled by prudence, or by fear of shame, or by awakening conscience: or, if the internal history of the actor discloses no facts throwing uncertainty on the event, the external circumstances may have made the act difficult or impossible. In a word, from the antecedent and conditioning facts, taken by themselves, we cannot infer the act with peremptory demonstrativeness, unless we have come into possession of an array of conditioning data, possessing a completeness which never perhaps was reached in any case, historical, judicial, or ordinary, exposed to such doubt as to leave an opening for argument in any shape. Therefore arguments drawn from other sources will be required in corroboration.

The analysis of this argument has thus been carried far enough to show what the kind of facts is among which materials may be sought for it; and perhaps also far enough to suggest some of its practical uses, and of the terms on which these are attainable.

Two or three hints may be subjoined:—

First, In the attempt to prove a fact, which we know to have been preceded by certain other facts, our first business should be the identification of all those precedent facts which seem to come up to the character of conditions. Antecedents which are clearly not conditions will be set aside as barren.

Secondly, Among the conditions, if clearly we do not know all of them, our task is that of discovering which (it may be one, or it may be a combination of more) appear to have an efficient causal bearing on the fact to be proved. All other conditions are often describable negatively, as constituted, in Whately's phrase, by the absence of obstacles. "If," says he, "the cause be fully sufficient, and no impediment intervene, the effect in question follows certainly; and the nearer we approach to this, the stronger the argument."

Thirdly, The individual conditions of an individual fact are often justly describable as being instances of a general or universal law. Such a law, accordingly, may be stated in its generalized form as a condition of the fact in question. This view would supply the substance of an exact deductive syllogism or syllogisms; and much is often to be gained, in ease of convincing others, by starting from such a general principle.

Fourthly, An argument of this kind may always be made impregnable against logical attack, by an exact and candid incorporation, into the premise, of the degree of probability which is assigned to the conclusion.

Lastly, and contrariwise, The fallacy most likely to be committed in the use of the argument is the over-statement, in the conclusion, of the degree of probability which was assumed in the premise.

2. The Argument from Symptom.

21. This kind of argument, the simplest of all, is sufficiently theorized in one proposition.

I. A fact being known which is conditioned by facts unknown, each or any of the conditioning facts may be inferred; and each of them, whatever be its character or its comparative importance, may alike be inferred with positive certainty.

The correlation put in question, by this kind of argument and the preceding, displayed but a cloudy prospect when we looked forward from facts conditioning to facts conditioned. If even one has failed among those facts which are truly conditions, the dependent fact has not taken place; and the possibility of such failure, so very seldom, if ever, totally excludable in questions here interesting us, alloys our conclusion with more or less of doubt.

When the correlation is viewed from the opposite quarter of the horizon, it brightens with broad and steady light.

Processes
constituting
Eloquence.

The character and limits of the argument from symptom—the relation of dependence.

Processes
constituting
Elo-
quence.

Evidently our position is now such as to dispel all uncertainty. If the dependent fact is known to have occurred, how much are we entitled to infer in regard to the conditions? Why, that *all* of them must have occurred. For, if it were not so, if even one of them had failed, the dependent fact would be non-existent. Therefore the dependent fact, and its relation to the others, being justifiably assumed, it is open to us to infer any one or more of the conditions at will.

It should be noticed also with emphasis, that the relation of causality is here utterly ineffective. From the effect we may of course infer the cause; but only because it is one of the conditions. We may, from the same datum, infer with equal certainty the most trifling or purely negative of the conditions by which the efficiency of the cause was limited; and a condition of this character may be involved so necessarily in the nature and origin of the dependent fact, that it may thence be inferable quite peremptorily, though the individual circumstances constituting the cause should remain undiscoverable.

Nor does it happen seldom that a dependent fact, and all questions as to its cause, derive their whole practical importance from the materials they yield for determining some one of those seemingly insignificant conditions. Suppose a man to fall suddenly dead this afternoon. The circumstances observed as attending his death, and those which are detected on dissection of his body, are symptoms from which medical men will, if required, endeavour to decide what the disease was that killed him; yet their opinions may rise no higher than conjecture, and though established, might be valuable only in the interest of science. But of his dying this afternoon it is a palpable condition, though in no sense a cause, that he must have been alive this morning; and his having been so may have opened to him and his family the succession to valuable property. There has recently been brought before the Scottish courts of law a question of this very kind, stirred by the tragical fate of Franklin's Arctic expedition.

In the use of this argument, the point to be worked most carefully is, the ascertaining that the facts sought to be inferred are truly conditions of the given fact, and of no other. They must not, on the one side, be circumstances which might or might not have been antecedents of the given fact; circumstances the non-occurrence of which would have left it possible that the given fact might still have occurred. They must not, on the other side, be circumstances which, though symptomatic of the given fact, are also symptomatic of some other fact or facts different from it. The fallacy to which the argument is exposed must consist in a violation of the one or the other, or of both, of these cautions: in the assumption that X is a condition of A when it is only an accidental and inessential antecedent; or in the assumption that X can be a condition of nothing but A, when it may be also a condition of B or of C.

In attempting to infer from any one symptomatic fact, it is very often out of our power, through the imperfection of our acquaintance with the real relations between A and X, to gain premises which shall be more than probable, or capable of justifying more than a probable conclusion. We are able to assert only this; that our X is more or less probably a genuine condition of our A, and of it only. Herein lies the weakness besetting single arguments of this kind. It is removed by the accumulation of symptoms, all of which found arguments leading to the same conclusion; while all of them converge in the closing argument, founded on the mere fact of the accumulation of probabilities, on the impossibility or high improbability of the concurrence being consistent with any conclusion but that whereto each of the separate arguments tends. Arguments from symptom, thus weak in isolation when the relations of the facts are obscure, may safely be alleged to be capable of becoming,

even in such a case, stronger by accumulation than arguments founded on any other kind of proof whatever.

Their weakness and their strength are alike instanced in that with which we are familiar in law, especially in the practice of criminal law, under the name of Circumstantial Evidence. Such evidence consists in facts founding arguments from symptom.

The doctrine of this kind of argument is not complete, until there is added to it the result of an original analysis made by Whately. This supplement is important enough to deserve being placed as a second leading proposition.

II. The Argument from Testimony is really an argument from symptom. Testimony is an assertion which would not have been made if it had not been true: so far only as the assertion and its truth bear this relation to each other, does the case possess the genuine character of testimony. The dependent fact, the A of the argument, is the fact that the testimony has been given; the condition, the X, is the fact that the testimony is true.

Faith in testimony is a rule of our conduct; distrust in testimony is only the exception. Accordingly, in trials at law, and elsewhere, also, when our knowledge of the facts comes wholly from the evidence of witnesses, we silently overlook the character of the source so long as there is no reason for suspecting that the source is tainted. We think out our conclusions from the testified circumstances, with the same confidence which we should have reposed in them if they had occurred before our own eyes. We do not think of the testimony as testimony, or probe it on that assumption, unless self-contradiction or other suspicious points raise distinctly the question, whether the witness has or has not told the truth.

3. *The Argument from Resemblance.*

22. This argument is easily recognisable when it is called The character and limits of the argument from resemblance—the logical flaw.
an Argument from Example. The question raised is, whether a given law, say P, is obeyed by an object *x*, whose subjection or non-subjection to that law we have it not in our power to determine by observation. We hold ourselves entitled to assume that the law is obeyed in at least one instance,—that is, by the observed object *a*. On the strength of this known instance or example, we infer that the law is obeyed in the unknown instance also. The point on which the theory of the argument rests, is the character of the relation between the known example and the unknown. They are referred to the same class (say S).

Our datum A is the assumption that a certain thing (say P) is true of a known individual *a* (or it may be more than one, but always fewer than all of the individuals constituting its class): our conclusion X is the assertion that the same thing (P) is true of the individual *x* not known unless as related to *a*. The relation on which the inference hangs is the fact, that *a* and *x* resemble each other in some point different from that which is in question. This last step in the dissection dictates the form of the inference. Resembling individuals are referred to the same class: therefore that which is held to justify the inference from *a* to *x* is, that the two individuals, the known and the unknown, are members of one class (S). The risk of error arises from this, that the comparison between *a* and *x* is made in regard to some attribute different from that on the common possession of which the class S has been founded.

The argument takes a shape like this:—*a* is a P; but both *a* and *x* are S's; therefore *x* is a P.

It seems to be certain (though there is one high authority to the contrary) that the reasoning is elliptical. An intermediate conclusion is taken for granted, but suppressed; and there are really performed two successive acts of argumentation, both of which are explicable (though for the first the explication might often be dispensed with, even for

Processes
constituting
Elo-
quence.

Processes
constituting
Eloquence.

logical testing) into syllogisms. The first of the two syllogisms is Inductive, being an inference from the particular or individual to the universal: the second is Deductive, being an inference from the universal to the particular or individual.

The skeleton of the inductive syllogism is laid bare in this formula:— α is a P; α is an S; therefore all the S's are P's. The conclusion gained by this induction becomes the major premise of the deductive syllogism, which may be formulized thus:—all the S's are P's; x is an S; therefore x is a P.

The deductive syllogism requires but a passing glance. Formally or logically it is faultless. If its conclusion is not certainly true, this must be because of some weakness in the assumptions it rests on. The minor premise, in which the unknown instance x is asserted to belong to the class S, can hardly ever be unwarranted. But its major premise has been borrowed from the preceding syllogism; and the method by which it was there come at is open to exception.

The inductive syllogism is logically fallacious. The flaw is an illicit process of the minor, which consists in inferring of "all" where we were entitled to infer only of "some," or "fewer than all." The premises would justify the conclusion, that "some of the S's are P's:" they do not justify the conclusion that "all the S's are P's."

The laws which are here operative prevail widely, not only in processes of communication, but over the whole domain of discovery and invention. The character of the "Inductive Philosophy" has been elucidated in various sections of this Encyclopædia, especially in the Preliminary Dissertations. In one of the special articles an attempt was made to show briefly, in accordance with the same principles which are here founded on, how, on the one hand, all our practical inductions are necessarily faulty in form; and how, on the other hand, all the laws which have been laid down for inductive discovery, from Bacon to Mill and Whewell, are nothing else than expedients by the use of which the formal error may be reduced to a minimum which is practically inappreciable. (LOGIC, especially §§ 102, 103.) The Perfect Induction, in which, from the sum of all the constitutive particulars, we infer the constituted universal, is logically faultless; but it is practically useless, because our data never embrace all the particulars in any case where it is worth while to infer at all. Our actual processes of this sort are always Imperfect Inductions, in which our known particulars fall short of the sum by a larger or smaller proportion, and which therefore can logically lead only to a conclusion falling correspondingly short of universality.

The philosophical principles which rule Induction as the great method of scientific discovery pass over without restriction into the rhetorical field. The results of induction there exhibit themselves as the foundation of that which is the most popular and striking, but also the most dangerous, of all kinds of argumentation.

The Argument from Example does exercise a peculiar force of impression, especially on minds imperfectly accustomed to analysis, or allowed little time for analysing. It seems to make a direct appeal to experience. The two objects, the known and the unknown, α and x , are, if the materials are well selected, known to belong to one and the same class, to have the same name, in respect that both of them obey a certain law (the S). The α is likewise known to belong to another class, to have another name, in respect that it obeys another law (the P), which is the law whose compass is really in question. The inference attempted is, that x also obeys the law P. The principle of the inference is, that the first law implies the second. If it really does so, the conclusion will be true, though not rightly inferred: if it does not, the conclusion will be false.

Whether the first law does imply the second, is a ques-

tion dependent on the exactness and success with which both laws have previously been examined.

The efficiency, again, of this antecedent scrutiny, will have been determined chiefly by the character of the matter argued about. The leading distinction is that which was indicated lately, between phenomena of the corporeal world and phenomena of mind. The former, taken as a class, admit of scrutiny, which, if instituted with adequate means, leads, though often by a long and tangled path, to positive knowledge in regard to all practical relations. The latter, taken as a class, are wrapped up in relations so complicated and obscure, that speculations as to human character and conduct must always rest within some or other of the degrees of mere probability. Universal laws are attainable, but are too vague to yield individual applications that shall be free from doubt; and laws of narrower compass intertwine and conflict together so incessantly and perplexingly, that the very satisfactory approach to certainty which we may usually attain as to large classes of events, diminishes as we narrow our classes, and dwindles into a succession of conjectures when we seek to carry beyond the verge of actual observation our acquaintance with the individual steps of individual human actions.

It is evident, in short, that, in argumentation about questions of the kind on which rhetorical rules have the firmest bearing, the Argument from Example is much more efficient for impression than for rational conviction; and hence much more powerful when addressed to unanalytic minds than when addressed to such as are acute in the taking of distinctions.

The outline of the theory may be set forth as follows:—

I. An attribute being affirmable of one or more, but not all, of the objects constituting a given class, we hold ourselves entitled to affirm the same attribute, with greater or less probability, of another object in regard to which we know only that it is included in that class. But the inference rests on the assumption, that the attribute in question is common to all the objects of the class, or is implied in the attribute or law on which the class is founded. This assumption is always reached illogically; and the truth or probability of the conclusion to which it leads is dependent on the amount of knowledge which is attainable, and has antecedently been attained, in regard to the objects compared.

When we speak of an argument from Induction, we mean, as has been seen, an argument embracing only the first of the two syllogisms constituting this kind of argument. The name of argument from Example or Instance should belong specifically to the elliptical argument, which passes over the universal conclusion to reach the particular or individual. If we speak of an argument from Likeness or Parallelism, we refer to this kind; and Analogy is an indirect likeness, not very clearly separable from likeness that is direct. Arguments from Unlikeness or Contrariety also are referable to this kind; for unlikeness or contrariety can subsist only between objects which are comparable as belonging in some view or other to the same class. When we speak of an Argument from Experience, we really refer to the antecedents of the argument, to the manner in which the data have been gained; and the argument itself is from Induction or Example.

(III.) APPLICATION OF THE CLASSIFICATION OF ARGUMENTS.

23. The leading use derivable from a classification of Cases on arguments, and the only use of it which has been systematized thoroughly by rhetoricians or dialecticians, is theory that which it is maintained to serve by aiding in the Discovery of Premises or media of proof. which the theory bears.

That the discovery of premises may really be aided by the possession of a well-digested stock of materials, is a truism.

Processes
constituting
Eloquence.

Processes
constituting
Eloquence.

It is hardly less a truism, that the digesting of materials may be facilitated immensely by the possession of a well-devised scheme of distributive principles. Now, it is doubtless true that every special department of human knowledge, every kind of matter that supplies objects to be reasoned about, has principles peculiar to itself, and affecting very extensively the distribution of the truths which constitute its system. But the rules of arrangement which are dictated by the peculiar principles, say of a science or of any other organizable collection of facts or laws, are no more than subordinate. They are over-ridden by other and wider principles,—principles which must be common to the given department with others, and which dictate higher rules of arrangement. These, again, fall similarly within the sway of certain principles which are the widest of all, and by which is prescribed the great outline of every system of knowledge.

It is scarcely rash to say that, for all those departments of knowledge whose objects are described as Contingent Truths,—for all, in short, which fall beyond the sphere of the exact sciences,—the highest principles of arrangement that can be reached are those, or something very like those, which lie at the base of the classification of arguments now expounded. In this or that department of knowledge, and in the application of arguments to this or that special purpose, the classification may be found to be quite barren of suggestions; but this will occur only because, for particular reasons, the arguments which are available lie wholly within one or another of the three divisions that have been chalked out. When the arguments accessible and required are such that they belong to different kinds from among our three, it will be found that the threefold scheme supplies a framework into which they will fall naturally and easily, and within whose several compartments all subdivisions prompted by the specific character of the matter will be distributable without confusion or intermixture.

Nor, even if the threefold scheme is not directly used, will the principles on which it stands be unfruitful of suggestive hints to those who care to master them and reflect on them.—The first point to be considered, when the discovery of arguments is aimed at, is the character of the conclusion for which we wish to find premises,—the nature of the relation in virtue of which the known and the unknown are connected in our thoughts, and are likely to be connected in the thoughts of others. Is our conclusion evidently a dependent fact? Our search is guided first and chiefly towards its conditions, the facts on which it is dependent; and among these we dig for some fact which may be accepted as a cause. If our conclusion is itself a fact on which we know others to be consequent, our exertions are directed towards the finding out, among these, of some which are not only consequent but dependent on it; of some in regard to which we may be assured that, but for the fact which is our conclusion, these could not be facts at all. But we may not be able to avail ourselves of either of these relations; and our incapacity may spring from either of two sources. We may not be able to discover any known fact as to which we can peremptorily assert, that it is directly either a condition of our conclusion or conditioned by it; or, still more frequently, although we can for ourselves trace the relation of condition as connecting our conclusion with some other fact, we may be satisfied that the connection will either be hard to be understood, or unlikely to be readily admitted by those whom we wish to convince. In either of these events, we are driven on the search for facts known to be in certain points similar to that which we desire to establish: we found on that acknowledged similarity, and on the classification and nomenclature which have their birth in it; and we found as strongly as we may on the presumption, that similarity in certain features implies similarity in others more or less directly allied to them.

Still more likely is it to happen, that even in the quarter in which our strongest proofs are detected, these are found insufficient to justify any reasonable expectation of our being able to establish more than a probability in favour of our conclusion. Such a state of matters puts us on the search for concurrent proofs of other kinds. To cases of this sort are referable considerations which will next be stated.

Processes
constituting
Eloquence.

24. The several Kinds of Arguments possess different degrees of Applicability to the different kinds of matter most frequently treated in argumentative discourses. The doctrine in regard to these differences has been sketched by Whately briefly but satisfactorily; and to his exposition nothing needs to be added but a few features on the margins of the plan.

Two remarks may be premised.—First, the cases in which it is worth while to consider such questions of applicability are those in which, whether on account of the character of the proposition to be established, or on account of the position of the persons to be convinced, it is anticipated that conviction will not be reached unless through several arguments all pointing towards the desired conclusion. In the next place, though all the arguments converge towards one focus, they are likely to converge by different paths, or to discharge different functions. Certain of them, describable as Probatory, will be those on which the stress of the proof mainly rests. Others will be Preparatory, serving the use of paving the way, whether by the removal of prejudices or objections, or by the imparting of prepossessions positively favourable. Others will be properly Confirmatory, as strengthening positions which the main group of arguments has not fortified beyond attack.

Practically considered, then, all the kinds of questions on which rhetorical theory has any effective bearing may be said to be three: Matters of Opinion, or, in other words, questions of principle, or questions in which the conclusion is a general or universal proposition, not the statement of an individual fact: Questions as to Individual Facts that are Past; Questions as to Individual Facts that are Future.

1. In the endeavour to generate belief in universal propositions, the arguments chiefly available are those from Condition. The weakness incident to each argument of this kind, taken singly, may be cured by accumulation; several concurring probabilities may yield positive certainty. These arguments are often aided, sometimes in the way of preparation, sometimes in the way of corroboration, by the authority of competent judges, which founds arguments from Testimony. In both ways, likewise, aid is furnished by arguments from Example, which are most efficient when close analysis cannot be relied on.

2. In the endeavour to generate belief in individual facts or events that are past, arguments from Symptom are made attainable by the nature of the case, and are those which are chiefly available. Testimony, founding arguments referable to that class, holds a prominent place. In all difficult cases, however, there are used, as preparatory or as corroborative, or for both purposes, arguments from Condition, (oftenest from motives), and arguments from Example.

3. In the endeavour to generate belief in individual facts or events which are future, the argument from symptom is of course excluded by the nature of the case. If the process of conviction is attempted on fair and legitimate grounds, and is addressed to minds competent in respect of ability and knowledge, the body of the probation consists in arguments from Condition; and arguments from Example are introduced only in corroboration. But if the process is unfairly conducted, or if the qualifications of the minds addressed are poor, the functions of the two kinds of arguments are very often and naturally reversed.

25. It remains to be asked whether the materials that have

Processes
constituting
Eloquence.

The arrangement
of arguments.

been collected, or others combinable with them, are capable of suggesting any laws for the Arrangement of Arguments.

There are just three relations of arguments which have been, or can be, alleged to determine the order in which they should be used. They might conceivably be arranged either according to their Kind, or according to their Purpose, or according to their Comparative Strength.

The third of these principles has dictated to rhetorical writers several canons, and particularly these two. It has been advised by some to arrange arguments by the rule of the climax, rising from the weakest to the strongest; and it has been advised by others to arrange them by a rule borrowed from military tactics, placing the weakest in the middle, where their shortcomings may be covered by the stronger forces that flank them on each wing. It is needless to examine or contrast either these two conflicting rules or any others derived from the same principle. For the principle itself is hollow and worthless. If an arrangement seemingly prescribed by it should be found to be effective, this can only be because there really lies under it a deeper law, either that of kind or that of purpose. In reference to strength, perhaps the only rule that could usefully be gathered is this: that arguments possessing no real force of conviction over those to whom they are addressed ought never to be used, unless they cannot possibly be dispensed with.

The only rules of real value that can be laid down for the order of arguments depend primarily on their kind, and secondarily on their purpose.

1. In reference to Kind, it should first of all be accepted as a rule, not to be violated unless for the most imperative reason prompted by special emergency of purpose, that arguments of the same kind are to be grouped together, no intrusion by arguments of another kind being permitted. A departure from this method cannot but give birth to confusion both of thinking and of expression.

As to the order of the several kinds, when all are available, required, and used, the natural and general arrangement is that in which the three kinds have now been examined. Causal arguments raise an antecedent or preliminary likelihood in favour of the conclusion; arguments from symptom support the conclusion more or less firmly by evidence derived from known facts seeming to stand in dependence on it; and arguments from example remove lingering doubts, by showing that the conclusion is at the very least not inconsistent with that which experience has shown to be true in similar or analogous cases.

2. The question of Purpose has, in effect, been raised in the last paragraph. The rule for the ordinary and normal arrangement of the three kinds of arguments is dictated by the consideration, that each of the three does ordinarily serve, better than the others, one of the three special purposes, preparation, direct probation, corroboration.

Purpose and kind, however, may and often do jar with each other.

The largest class of cases is that in which the causal relation is not likely to be distinctly apprehended, and in which therefore the argument from condition is unfit to act as preparatory. The remedy oftenest applicable is one already noted for a different purpose: the office of preparation is devolved on the argument from example.

The conflict between kind and purpose becomes yet more decided, when an argumentative discourse is addressed to persons labouring under opinions or prejudices strongly adverse to the conclusion which the debater desires them to entertain. Adverse prepossession, indeed, is always to be supposed possible where the writer or speaker has not the first word. Accordingly the question here arises, What should be the place of Refutation? The unfavourable position of an argumentator who has to make the refutation of an adversary the main part of his task,

may justify a farther deviation from rules than any other circumstances he could be placed in. The more deeply the counter-opinion may be supposed to be rooted in the minds of the recipients, the earlier should the refutatory treatment be entered on. An opinion which we wish to sow cannot make even the beginnings of germination, till opposing prejudices have been rooted out.

Processes
constituting
Eloquence.

III. THE PROCESS OF PERSUASION.

26. To this process, as presenting the field on which are The championed the most dazzling triumphs of oratory, the name of Eloquence is very usually given by way of eminence; and the theory of Eloquence is hence the distance is short to that closer limitation, hardly less common, which refuses the name of Eloquence to all communicative processes, except such as either entertain the design of persuasion, or exhibit a preponderance of its distinctive elements. Against all such limitations a protest was taken at the beginning of this treatise.

It is true, however, that we have here that compartment in the domain of Eloquence, which is not only the most powerfully and generally interesting, but more readily susceptible than any other of being subordinated to a theory that is peculiar and independent. In imaginative and emotive eloquence, doubtless, much more thoroughly than in that which is merely argumentative, brilliant success is unattainable, unless when its foundation is laid in native genius. Yet reflective study of the discoverable laws of the process will not only guide and strengthen, for results useful and even eminent, powers of all degrees below the highest, but will teach to the highest powers themselves much that may advantageously direct and plume their flight. The ship that is bent on a dangerous voyage must indeed be ably commanded and fully manned; but her captain does not set sail till he has obtained the most accurate charts. The rhetorical laws of persuasion, though their use presupposes the possession of an ability and knowledge which they cannot impart, do yet possess extensive uses, negative and cautionary. They are the charts of a broad and stormy sea, whose currents are heady but not lawless, and whose soundings, though deep, are not beyond the reach of the plummet. Eloquence, in this its loftiest region, not less than in regions that are humbler, is decisively an art, a process whose steps are dictated by preformed design, and whose theory is discoverable and has been discovered. It stands in no way differently from other arts demanding and rewarding the exertion of elevated energies, in having, as conditions imposed on all applications of its theory, such maxims as these: That the use of all rules of art is chiefly no more than negative and prohibitory; and that, even for such purposes, the utility arises, not from the rule itself, but from intelligent and complete apprehension of its principle.

Our psychological analysis of the mental process which may issue in volition, must now be kept carefully in sight. In its normal shape, the process unfolds itself as constituted by at least two steps which are characteristically cognitive or transcend cognition: the first, a fact of Imagination; the second, a fact of Wishing, whether desire or aversion. On the latter of these the volition follows. Not less incumbent on us is it to remember, how this most prominent series of steps is modified by attendant Emotions. While it was maintained, in the psychological outline, that the emotion is really an obscure concomitant of each of those steps, it was observed, also, that the emotion may force itself into prominence as a step intervening between each two of them. Indeed, the substance of one part of the doctrine which was laid down is this: that in proportion to the force of the cognitive or higher fact will be the certainty that the Emotion (at first overpowered by that fact) will recur, and in its turn become

Processes
constitut-
ing Elo-
quence.

prominent. It must now be alleged broadly that Persuasive Eloquence aims at the generation of a process in which the cognitive and higher steps shall have such force *as to bring up a consequent emotion at every step*. In the most advanced stage of our researches we may have to glance at cases proceeding far towards the completion of the process. Complication also of the cognitive and higher steps, such as those which were pointed out when we specially examined volition, would suggest considerations having much value for the dissection and treatment of complex and exceptional cases. But such questions may be ignored while we investigate the general theory of Persuasion. The main reason why they are inessential is this: that the determining steps in the process are the first two. The others are ruled by these; and, if repeated or varied, they must be so through and after repetition and variation of these their antecedents.

Let this, then, be remembered as a cardinal point:—that the theory of Persuasion is virtually complete, when it has determined the laws regulating the generation of the first two steps: that in which the prominent fact is the *Imagination of the object*, the wish for which is to be the prompter towards action; and, next, that in which the prominent fact is the *Emotion which is consequent on the Image*, and which must be excited before the wish can have birth. The process whose laws we have to seek is the generation, through language, of Images excitative of Emotions tending towards desire or aversion.

The field thus staked out may be fenced off in sections. In the first place, we cannot safely, at any stage of our survey, accept anything but the Images as our chief object of scrutiny. Everything of specific doctrine that is attainable and useful relates primarily to the images; and it relates to the one or the other of the two aspects which must be combined in a complete inspection of them. The positive and specific laws of persuasive eloquence, accordingly, fall into two sections. The first of these contains Laws of Form; and those laws fall into two sub-sections;—laws affecting the Images, and laws affecting the consequent Emotions. In both parts of this section we are absolved from all obligation to consider the further tendency of the emotions. In other words, the laws here emerging are common to Eloquence and Poetry. In the second section we retire into our own exclusive territory. The laws contained in it are Laws of Matter; and the question here arising is, what kinds of objects are, when imaginatively represented, likely to operate, through desire or aversion, towards the excitement of volition.

In the way, however, of introduction to these two groups of determinate laws, certain considerations should be suggested, which, although not perfectly digestible into a system, may yet be methodized to a certain extent; and which deserve to be classified, as forming a section of preliminary and general doctrines. Our sections of laws will thus be three.

(I.) LAWS OF PERSONAL RELATION.

The law of
adaptation
—the posi-
tions of the
two parties.

27. Persuasion, like every other communicative process, is a game which must have at least two players. The parties, it is true, hold attitudes which through all changes are opposed to each other: the one is steadily aggressive, the other only defensive or receptive. Our chief attention is rightly given to the active side; but the position of the side which is comparatively passive can no more be neglected with safety, in the attempt to understand the evolutions, than it can be in the actual performance of them.

A maxim which might be called the Law of Adaptation runs through the whole theory of communication, like the heart-strand round which is twisted the cordage forming a rope. The duty of the operator is not that of making good

his own position, but that of reconciling his own position with the position of the persons operated upon. This is strictly the fact even in exposition and argumentation; and, in the performance of these processes in individual cases, the necessity of adaptation presses itself on every intelligent debater. But in the general theorizing of processes aiming at the communication of belief, the maxim is not forced into that prominence which it imperatively exacts when we begin to look into the theory of persuasion. In the attempt to generate belief, the communicator and the recipient stand rather in different postures than on different ground: in the attempt to excite imagination and emotion the ground is different as well as the posture. Here, therefore, the active party of the two is urgently called on to consider the relation of the other.

Imagination, and consequent Emotion, are to be excited by the discourse. Accordingly the images must be presented both vividly and in their emotive relations; and the communicator must possess adequately both imaginative and emotive susceptibility; while, besides these qualifications, he must also have power and skill of language sufficient for due expression both of the images and of the emotions. It is no less true, on the other hand, that the process, even if fitly performed, will fail of all effect, or be but very partially successful, unless the recipients be on their part fitly qualified. Fortunately, however, the qualifications needed on this side are lower in degree and rarely wanting. Susceptibility is quite as frequent and as keen in those who hear or read as in those who speak or write. Imagination, too, of that receptive character which can readily form a scene or a character whose features are drawn for it by a stronger hand, is a gift diffused with beneficent abundance; and therefore the field of influence is widely open for that self-dependent power, so much more rarely given, which weds its scattered experiences into unions so novel and inspires its images with a strength so life-like, that we rightly call such imagination original, and exaggerate but excusably in describing it as creative.

A further step of dissection is required, both for justifying one of the demands which are thus made on the orator, and for founding more than one corollary which will find a place hereafter.

It was asserted that one who is to excite others to feeling, must himself not only imagine but feel. The assertion is common-place and universally admitted: its reasons may reward a little scrutiny. Those to whom emotive images are imparted are acted on by them in each of two ways.

In the first place, the images operate Directly, through their own objective force. An image representing an interesting object cannot fail, even though it should be inefficiently imparted, to excite emotion in a mind which possesses activity of imagination enabling it to frame the image for itself from the hints that have been set before it. The same image, if exhibited with the fullness and brightness of oratorical genius, will excite emotion in minds which would not be excitable under less energetic prompting.

In the second place, the images operate Indirectly. They do so when they are presented in an aspect shewing their having excited, in the mind of the presenter, emotions of the character which he desires to transmute into the minds of others. In a word, they operate through the great Law of Sympathy. Of this mighty spring of human emotion, and desire, and action, we must never allow ourselves quite to lose sight while we endeavour to trace the workings of emotive eloquence. If there were room for illustrative description of its effects, these might most wisely be given in the beautiful declamation with which Quintilian strives to enforce the law of emotion on the orator. It should be remarked, particularly, however, that, in all attempts at passionate excitation, sympathy must, whether we will or not, be active either for us or against us. An image which

Processes
constitut-
ing Elo-
quence.

Processes
constituting
Elo-
quence

we have fancied but faintly or depicted but poorly, may thence derive great emotive efficacy, if only it has evidently affected ourselves deeply. An image strongly framed and brilliantly expressed may have its moving power multiplied a thousandfold, by the evidence that it has deeply moved ourselves. But if, even when such an image has been displayed, we, the framers, are cold under its light, there is imminent risk that those who watch us will be infected with a sympathetic chill.

(II.) LAWS OF FORM.

The formal
doctrine
of emotive
imagery.

28. Inquiry into the form of the emotive images,—the manner in which they may be represented effectively,—calls our attention necessarily towards the Words in which they are expressed. All the laws of form gather some of their data from truths directly involved in the functions of language; and this is the fit place for so much as is genuine and useful in those cumbrous Rules of Style, which have been constructed as aids to imaginative and passionate eloquence. But here, as elsewhere, the reasons of the rules will occupy us more than the rules themselves.

The whole doctrine of this first and decisive step in the process of persuasion, rests on those Laws of Imagination which were outlined in our psychological introduction.

The deepest courses of the foundation are laid in that primary law, which limits imagination to objects thought of as Individuals.—Fencing the class of imaginable objects round about by this impassable barrier, we must, however, beware of shutting out certain kinds of objects, which, though very abundant within the domain of imagination, do often lie dangerously close to its frontiers. We must steadily avoid the error of supposing, that objects of sense are the only objects that can be imagined. In philosophical strictness, indeed, such objects are imaginable only as having been, or as being capable of becoming, objects of perception; that is, as having been, or being thought of as being, factors or elements in mental facts. But in imagination, as in perception, their objective characteristics monopolize the attention so thoroughly, that the subjective side vanishes altogether from spontaneous consciousness, and is recognisable only through energetic reflection. It is likewise true, that our imagining and remembering of objects perceived is beyond all comparison more clear and vivid, than our imagining and remembering of facts of consciousness in which perception has had no part. So widely does this law rule, that our imagining of facts purely mental has to be made clear and bright through analogies drawn from our ideas of corporeal phenomena; a truth which is instanced in every word or phrase by which we strive to express mental facts. This difference in ease of imaginability, between objects of the one class and objects of the other, will immediately be put to use. But it must be remembered firmly that objects of the one class are imaginable as well as objects of the other. Nor is it too early to note this truth on the other side; that, while our imagination of corporeal objects is the more vivid, our imagination of mental phenomena is in a like degree the more interesting or excitative of emotion. Indeed it is only through their relation to mind that external objects, whether perceived or imagined, are interesting or emotive at all.

Another point of doctrine having a broad applicability to the theory of persuasion is this.—Imagination, of the kind which has here been called synthetic, has a much wider sway than that which we are apt to assign to it. The listener who seems to be merely gathering in passively the sweet fancies expressed in a recited poem, or the stirring pictures painted by a fervid orator, is really, if he does form the images for himself in the faintest degree, performing an imaginative process of the very same kind,—a process constituted by facts obeying the same laws,—as that which, in

the mind of the poet or the orator, has given birth to the imagery by which his derived activity is prompted. The difference between the two processes is a difference in degree. The recipient must synthesize as well as the communicator; although he does synthesize from materials whose exuberance makes his task easy, and is able after all to form only a picture which almost always is as dim as the last rays of twilight, in comparison with the tropical sur-shine of the imagery whose hints he strives to re-compose.

By thus placing ourselves close enough to the recipient to see clearly the position he truly holds, we gain a glimpse of the relations between him and the other party, which invites us to examine more minutely the ground that lies between them.—No image formed in one mind can, by any medium of communication that is either possible or conceivable, be transfused into any other mind with either complete or exact similarity of elements. The image as it lived in the mind of the original imaginer is one thing: the image which the attempt to communicate it has evoked in any other mind is another thing. Besides the immeasurable shortcoming caused by that shortcoming in imaginative power which was pointed to in the last paragraph, there is a shortcoming (and this the only one against which any precautions can be taken) arising from this fact:—that the original image has been communicated through certain media, each of which is inadequate in its own peculiar way, but all of which have imperfection of efficacy as a common characteristic, an imperfection disappointing to the inventor and crippling to the mental mobility of those for whose excitement the invention has been framed. What is the most exquisite statue or the most masterly painting, to the vision of grandeur or of beauty which hovered in the airy dreamland of the artist's fantasy, undimmed as yet by the shadows of that common daylight in which he had to aim at giving it visibility, and undeformed by the jarring of those mechanical obstacles against which he was to contend in giving a body to its likeness!

The fact lies straight in our path, that imperfections, different both in kind and in the specific character of the result, but still great and unavoidable, impede all attempts at the communication of imagery through language. In each of the points which are exposed to danger,—in respect of completeness and in respect of exactness,—the communicated image, the image raised in the recipient mind, is made, by the imperfections specially incident to language, to be more or less, and often very far, dissimilar and inferior to the image by the expression of which it was suggested. The picture or the statue is one visible thing: an observant spectator, if he shuts his eyes and remembers what he has seen, is in possession of an image which represents with reasonable correctness the work of art, however far it may fall short of the artist's ideal. The suggestive weakness of the arts of design lies in their tendency to let us rest content with mere sight and memory, instead of attempting to soar to the imagination of the artist's creative thought. The suggestive weakness belonging to language operates in a different direction. If an image so communicated is operative at all, it cannot be so by being merely excitative of memory; for there is nothing to remember, the words being mere symbols, empty till they suggest the relative ideas. Suggestion must take place: poetry and eloquence are excitative of imagination through suggestion, association of ideas, and through that channel only: the doctrine is of great value in the theory of both arts. But, in either of two ways, the object suggested may not be of the kind it should have been. On the one hand, the words expressing the image may suggest some image widely different; or, on the other hand, they may suggest some mental process which is not imagination at all, or has not imagination for its most prominent element.

Processes
constituting
Elo-
quence.

Processes
constituting
Eloquence.

The modifications under which the several failures thus hinted at are most likely to occur, will appear in some degree if we take them as illustrations of two leading propositions, under which may be specified all that is essential to the formal doctrine of imagery designed to excite emotion.

The laws of
direct representation—imagability, succession, specification.

29. (I.) The shortcomings incident to the result of attempts at communicating emotive imagery through language, are traceable to Three several Characteristics inseparable from the method of communication.—*First*, The communication takes place, not directly through perception or simple reproduction, but through suggestive relations prompting an act of synthetic imagination. *Secondly*, The suggestive ideas are communicated, not simultaneously, but successively. *Thirdly*, The symbolic character of words, while it is the foundation of their pre-eminence among all media of communication, does yet impose on them certain specific disqualifications.

(i.) Evidently, the restrictions imposed by the first of these considerations do not well admit of being formulized into specific rules. The doctrine, however, accompanies us through all more minute inquiries, and is always to be remembered as constituting a condition precedent, under which only these have truth or value. Perhaps it may be worth while to work out of it two corollaries, which, vague as they are, come in contact at more points than one with the relation between the communicator and the recipient.

First, The formation of the image by the mind recipient is the easier, in proportion as the image which the words are designed to express is the simpler, or constituted by the fewer parts or elements capable of being separately imagined.

Secondly, While the character of imaginable objects, and that of the process issuing in synthetic imagination, concur in making it impossible for any image so formed to be absolutely simple, an image expressed in words must, on account of the indirect character of the method, be even less simple, or must be constituted by a larger number of imaginable parts, than an image of the same object might have been if it were the simple reproduction of what was given in perception. Consequently, in representation of this kind, the relation between the parts and the whole demands a recognition especially emphatic. The formation of a complex image by the mind recipient is the easier, in proportion as the image which the words are designed to express possesses unity, or (to speak more accurately) systematic totality; that is, in proportion as all the constitutive ideas are evolved in subordination to one prominent and paramount idea.

The pre-requisite for the application of these principles to practice, is the successful striving, in the formation of the image in the mind from which it is to issue, after the closest possible approach to simplicity, and the utmost reduction of complexity to its central and combining law. Such success can be won only by vigour both of imagination and of judgment; and these are not the fruit of rules. Nevertheless, the aiming at a mark too distant to be hit is excellent practice for the shooter; and in intellectual as in moral aspiration, the station which we struggle to attain cannot be too high. We are helped also by every hint, which clears up our idea either of the end we are to look to or of the means which lie between us and it.

The hints thus thrown out stand in no real contradiction to a maxim which has frequently been assigned by rhetoricians from Cicero downwards. It recommends Circumstantiality as an excellence in a word-picture drawn for the purpose of aiding persuasion. That a certain complexity of features is indispensable, was broadly asserted in our second corollary. It may farther be allowed that emotive images must generally have greater fulness of parts, and

Processes
constituting
Eloquence.

consequently of expression, than that which is either required or advantageous in the thinking and expression of argument. But when circumstantiality is advised, it is only meant that there shall not be wanting circumstances, features, incidents, sufficient both in number and in character to suggest lively images, and to present these in interesting relations. It is a question of particulars, how far the elaboration ought to go. Sometimes brevity, and a brevity that is extreme, may be dictated by the position of the auditors. Some of the most hasty of those thunder-flashes which dazzle in the orations of Demosthenes, are shot forth briefly, because they are references to facts as familiar and as exciting as their daily life to every one who heard him. Oftener account has to be taken of the powers of the poet or orator. High genius possesses strong tools, for the want of which ordinary talent must make up by the use of others that work more slowly. But, on all sides beyond and around, expatiation is hemmed in by the principle of our corollaries. Fulness of detail tempts both towards tediousness and towards confusion; and the two are equally hostile to the easy and vivid excitement of imagination in those who suffer under them.

(ii.) The law for which the ground is cleared in the second of the characteristics laid down in our theorem, owes the most valuable illustrations it has received, to Lessing, by whom it was first distinctly exhibited and put to use, and to Vischer, the latest of those who have systematically expounded it. It comes to light most readily in a comparison between the procedure of poetry and that adopted by the arts of design; and it is in aesthetics only, or specially in the theory of poetry, that it has hitherto been fully used. But it rules not less directly in the imaginative section of eloquence.

It rests on two pillars. On the one side stands the peculiar nature of the process of communication by language, as working through *succession*: over against this foundation stands the *independent activity* which must be exerted by the receptive mind, and which may and must be exerted more freely when language is its prompter than in any other case.

While the arts of design represent in space, literature represents in time. The former, therefore, barred from representing change and succession, are strong in the representation of simultaneity: visible objects of considerable complexity are representable in sculpture; and painting is limited in its accumulation of features by nothing but the bounds within which the eye can take in a scene as one whole. Language, in its picturing forth of images, is not indeed shut out from the representation of simultaneity so utterly as those arts are from the representation of succession: language, in its grasp of objects, is infinitely more elastic than visual perception; and this mainly because it hints to the mind rather than dictates to it, and is thus not so truly the instrument of art as the mover of imagination the real instrument. Still, in respect of the expressed image (which, not the image raised in the recipient mind, is here in view), language is on this side hemmed in within a very narrow territory. Its strength, its characteristic field of adventure, lies in the representation of change and succession.

Therefore, in the first place, language, as a prompter of imagination, has, as its royal appanage, the domain of mind, not that of body. The field over which it bears sway, the class of objects which its nature fits it for representing, is constituted by mental phenomena, the very essence of whose manifestation is succession and change, phenomena which are not cognisable in consciousness otherwise than as successive changes. This is what its operation in time empowers language to do. Let us ask, next, what that operation prohibits it from doing.

Language, then, as a prompter of imagination, has hardly

Processes
constituting
Eloquence.

any power at all in the direct representation of objects of sense. Such an object must be simple in the extreme, if words can paint it so as to excite an image at all like the original. As to the giving of expression to the physical characteristics of external things, the sciences descriptive of body (especially those dealing with bodies organic) bear testimony to the difficulty which words have in performing the task; though patient study of descriptions is there demanded and granted, and though the resultant scientific idea of the object is not required to come up to a complete reproduction of its visible appearance. But he who, treating a corporeal object, designs his language-picture of it to be at the utmost a sketch, from which a mind-picture of it shall be painted by others, does, on the one hand, desire to create in those other minds much more than a scientific skeleton; while, again, he is not entitled to expect that those minds shall work out the result through exertions of untiring industry. If the object is very complex, the features of it which were first described may be absolutely forgotten before the description arrives at the last: it will be impossible, also, to avoid raising subordinate elements into so undue a prominence as to generate confusion worse confounded; and, over and above these difficulties, the weary pain of the continuous effort which the receptive mind is commanded to make, must throw it out of the imaginative mood either into inertness or into conjectural questioning. Nor is this all. If the receptive mind possesses its needful share of imaginative activity, its own energy will speedily free it from the dominion of its task-master. From some of the earliest suggestions conveyed to it, it will begin to frame fancies for itself: it will attend to these, not to the later hints of its instructor; or it will catch up these hints as sounds are caught by a man half-asleep, and weave some of them, with its own visions, into a web to which the words it hears have lent but few threads either of warp or of woof. In fine, when a description is vaunted as "pictorial" or "graphic," it may be that the epithets are used in a sense in which they denote a real excellence. Oftener and more naturally, they signify what is not a healthy growth of art, but an excrescence symptomatic of disease.

How is the cure to be found or the distemper prevented? By the translation of simultaneity into succession; by guiding our words to the representation, not of something which is here or there, but of something which (standing in a suggestive relation to it) was in time past, and is now changing to something else, and will hereafter change into yet another thing. Suggestive language represents bodies through their changes: its sphere is action, not that which acts or is acted on; its world is a world of motion, not of rest. Yet further, it cannot represent what has been called the action of bodies, otherwise than through analogies with action proper, the activity of mind, or with some or other of those mental changes out of which action issues or in which it seeks its consummation and its end. Individual changes of body become known to us only through individual changes which they excite in our minds. Even if the bodily change is the thing which we desire to make the leading object of the image,—yet the mental effect, whether feeling, or wish, or volition, or thought, must come up and be expressed as that which will individualize the image of the corporeal excitant. If that which we desire to make the prominent feature of the image be any of the relative mental changes, the corporeal attributes sink necessarily into the background.

The corporeal class of attributes will be the prominent features if we aim chiefly at *making the image vivid*,—that is, at intensifying the *first step* in the persuasive or poetical process. The mental class of attributes will be the prominent features if we aim chiefly at *making the image emotive or interesting*,—that is, at intensifying the *second step* of the process. But neither class can ever be wanting in our own formation of the image; and neither class can

ever fail to find expression in the words by which we communicate that image.

The law, then, into which the hint thrown out in the second characteristic has effloresced, may be drawn to a point in some such shape as this.—As a process operating through succession and change, imaginative and emotive representation through language has mental changes assigned to it as constituting its a-thinctive sphere of objects: and, in the endeavour to represent corporeal things, the process is limited to the expression of changes loosely describable as actions, and standing related to action proper and its mental concomitants.

(iii.) The third of the characteristics calls for less explanation. It points at the power which language has, not only of exciting imagination, but of prompting thinking proper,—that is, especially, the formation of concepts, and general reasoning through these. As being symbols through which we can think, and as being the only kind of symbols through which we can think to good purpose, words are essential conditions of our ability to extend our thoughts beyond the individual to the universal, from objects taken in isolation to classes which objects constitute. We are enabled to do so through our possession of common terms, the names of classes: by seizing hold of these, we swing ourselves upward out of the clear but not elevated region filled by singular terms, the names of individuals.

But the law of compensation rules in the whole world: every good thing must have its price paid. Common terms occur continually among our words; because the idea of a class is continually springing up among our thoughts. Consequently language is constantly tempting us out of the field of mere imagination, into one which lies indeed on a higher level, but which yet, being a different field, may be one we did not wish to enter. It is absolutely impossible that an image expressed in words should stop short with exciting the imagination of those who receive it: it must excite judgment also; it must set them a-thinking; it must lead them, for a short way or a long one, into trains of reasoning. This is, in one view, a mighty and a blessed effect. Eloquence would be powerless were it not produced: poetry without it would be a mere plaything; poetry is dignified by it with its prerogative as one of the great rulers (though a ruler not sitting on the highest of the thrones) of human thought and of moral activity. In a view which is raised more directly by our present studies, the tendency even of imaginative language to prompt judgment is a weakness; and language used in persuasive representation must be strengthened against it.

The weakness is universally acknowledged; and rhetoricians, whether able or not to detect its most remote sources, have hardly ever failed either to discover the remedy or to describe it with sufficient clearness. A place is usually given to it among the rules for attaining that quality of style which is called Animation or Vivacity; by which is meant an aptness of language for exciting imagination and emotion. The common rule may be fitted into the system here under exposition, by being framed in such a shape as the following:—

Singular terms, the names of objects thought of as individuals, are the only terms which are directly suggestive of Imagination only, to the exclusion of other modes of thought. These, then, are the words fittest to excite images, and are preferable to all others when they are obtainable, and when no concurrent aim forbids their exclusive use. But common terms, the names of classes,—which do not suggest imagination (or individuality its object) otherwise than indirectly and incidentally,—must and should be of frequent occurrence. Now, that indirect suggestiveness of individuality, which is possessed by common terms, is in the inverse ratio of the extensiveness of the classes they denote, or in the direct ratio of their specification or approach to individu-

Processes
constituting
Eloquence.

Processes
constituting
Eloquence.

ality. Therefore, for the excitement of imagination, when an idea may be expressed by either or any of two or more common terms, the Less Extensive Term should be preferred to the more extensive. A special method, which is both common and very effective, is the limitation of the species or characterization of the individual by Descriptive Epithets.

The laws of

presentation,—
tropes and
figures.

30. In the last section we have studied the nature and the partially applicable remedies of certain failures in effect, which are due to imperfections cleaving inseparably to the process of communication by words. There will now pass before us certain failures in effect, which may or may not take place, but which do take place frequently, and which are attributable, not to anything in the process, but to something in the matter it works on, or in the relation of this matter to the persons whom the communication is designed to affect.

It is desired that by these persons the object represented to them shall be imagined vividly, and shall excite consequent emotion. But the object may, while it is nevertheless one which must be impressed as strongly as possible, *be either more or less difficult to imagine, or more or less deficient in emotive interest*; and this, either because of its own nature, or (more frequently) because it is ill understood or little cared about by those on whom the thought of it is to be urged.

Against the evil issue thus threatened,—of inertness in imagining, or coldness in feeling,—provision is ministered through that broadly beneficent power of language, to denote all objects and suggest all modes of consciousness, which came in our way a little ago as one of the obstacles impeding imaginative suggestion. Words prompt us, not to imagine only, but to judge, reason, compare. Our object cannot fail, no object can, to be susceptible of becoming a term of comparison: for it must be classifiable, through resemblance, analogy, or some other relation, with innumerable other objects; and among these we shall certainly be able to discover some, which do not labour under any of the defects disqualifying the primary object. Such secondary objects will suggest the primary one; and, in virtue of the laws of suggestion, the cognitions and feelings which they have excited will be transferred to it, as elements of a new mental fact of which it becomes the object. The mental eye will now see the object in a shape to which those others have given improved distinctness; the mental eye will now see it through a light into which the warmth of their colours has been transfused.

These are questions touching the matter of images as well as their form. But they are most conveniently treated here, not later; because the expedients dictated by the answers to them issue in transformations of language. The principle of these, as just explained, is hinted at, and the kinds of expedients worth theorizing are named, in the following proposition:—

(II.) The flexibility, and the compass, of the suggestive power possessed by language, concur in bestowing on processes of suggestive representation which take language as their vehicle the capacity both of vivifying imagination and of intensifying emotion, by the use of what may be called Indirect Representation. This consists in substituting, for the image which it is desired to excite, the image of some other object, relative to the object of the first and therefore suggestive of it. The principal method of indirect representation is the use of Figurative Language; and the introduction of Illustrative Examples rests on the same principles.

Figurative language embraces two forms of expression: Figures proper, and Tropes. The best of our English books on style (Irving's) takes exception both to the correctness and to the usefulness of the distinction between

the two. But it must be said, with deference, that neither of the exceptions appears to be well founded.

Of the Trope proper the most prominent example is the Metaphor, which suggests through similarity. In the trope, a word or phrase is turned from its usual and appropriate meaning; signifying most obviously one object, it is used to denote another object, which in some way or other is like the first. The Figure proper is exemplified in the Apostrophe and the Exclamation. In the figure, the words are used in their obvious and appropriate meanings; but the form into which they are combined is prompted by emotion of the speaker. Another example, and a very instructive one, is the Interrogation. The question is not a figurative expression when it is really put with the wish of obtaining an answer: it becomes figurative when it is (and often and naturally it is) merely a passionate way of expressing an assertion. I am not speaking figuratively if I ask for information,—“What o'clock do you suppose it to be?” I am converting the question into a figure, if I intend under it an indignant remonstrance against delay in the arrival of a railway-train. There are, it must be allowed, figurative forms of speech whose place is open to controversy: the question arises, whether they are tropes or figures. But the principle of the distinction is quite broad enough for fixing the class even of these; and, it may be hinted, the fact of the doubt should teach caution in the use of such forms; since it must arise from some uncertainty or imperfection in their operation. The Simile is the most notable of these. In a very strict view, it might be denied to be a figurative expression at all. It is merely an assertion that two objects are like each other: it is the datum of a Metaphor. This relation, however, leads to a description of the simile which is more just to it: it is a metaphor in embryo, a metaphor in the first stage of its development. The Allegory (proverbially the most “headstrong” and dangerous of all figurative forms) is easily disposed of: it is just a concatenated series of metaphors.

In form, then, or as modes of expression, the Trope and the Figure differ. Do they differ correspondingly in their mode of operation on those to whom they are addressed? They do, on a principle which we have already recognised as effecting very extensive differences in the steps of persuasion. Tropes operate *directly*; but Figures operate *indirectly*.

A Trope directly excites the imagination to the formation of the image wanted. Its motive power is rooted in the character of the two correlated objects, and in the suggestive influence which that correlation exercises. The result which a spoken trope produces, in the mind of the hearer, is an image of the primary object under the change of aspect caused by its being viewed from the side of the secondary object; and the emotion which likewise is excited is consequent on this step.

A Figure excites the imagination to the formation of the image, not directly through any suggestion of an image painted by the words, but indirectly through Sympathy. The imagination does, in fact, seem to be excited by a reflexed path, being prompted by emotion. A figure of speech, as being prompted by emotion, is symptomatic of emotion on the part of the speaker; and the recognition of this fact rouses sympathetically a similar emotion in the mind of the hearer. This communicated emotion leads back to imagination of the cause which has moved the mind of the speaker; this cause is, or suggests (but in a changed and emotive aspect), the primary object, that which the speaker wishes us to imagine; and the emotion which is to lead us to desire or aversion is consequent on those antecedent steps.

If this analysis is in the main correct, it justifies more than one practical corollary, exhibiting marked differences in

Processes
constituting
Eloquence.

Processes
constituting
Eloquence.

the comparative availability of the two kinds of figurative expression.

First, Deliberate selection of objects and expressions, guided by intelligent application of rules, may add much towards the efficient use of tropes. But the use of figures will always be inefficient, or even displeasing, unless when it is prompted by genuine and spontaneous imagination and emotion.

Secondly, The prevalence of tropes on the one hand, or of figures on the other, tends, more than any other feature referable to style, to determine the character of eloquence as being more or less animated or passionate. Figures, being symptoms of emotion, are the key-note of animated communication; although plainly the abuse or over-abundance of them degrades eloquence into declamation or rant. A style which is poor in figures is not relieved, by abundance of tropes, from the risk of being deficient in the power of exciting strong emotion.

Thirdly, Tropes may be said to be equally effective in their way, whether the words expressing them be heard or only read. Figures do not reach the climax of their suggestiveness till they issue from the lips of a speaker. The most pregnant expressions of emotion, recorded for calm perusal in after-days, cannot work with a tithe of that sympathetic force and immediacy, which the spoken words possess when they are aided by the voice, and the gestures, and the countenance, and the whole living and present activity of him who utters them.

Fourthly, Besides other restrictions and distinctions which are almost self-evident, it follows that spoken oratory must owe very much of its suggestive effectiveness to the prevalence of figures; and that orations whose style is deficient in figures will fall with comparative coldness on the ear to which they are first addressed, even though richness in tropes or in other forms of imagery may make them, when recorded, singularly attractive to readers. Two of the most eloquent of all men supply illustration by contrast. The style of Burke is luxuriantly tropical; and of the few figures which he uses, almost all belong to the least lively kinds. Admirable as his speeches are, and finely and vigorously as his scenes, and personages, and feelings strike us when we study them in the closet, there is sufficient proof that his impressiveness as a parliamentary orator fell infinitely short of the fame he had and has through the publication of his addresses. The one prominent characteristic of his style goes far towards accounting for the fact. Of Demosthenes, believed to have been the most effective of all public speakers, it has been alleged that he has no tropes at all. It is true that he has very few; and these are slightly and sketchily touched. But in figures he abounds beyond any other orator, ancient or modern. It is only in his business-passages that he rests contented with a succession of calmly-stated propositions. Whenever he is himself excited, and wishes to excite his hearers, assertion rises into the figurative forms which it wins from passion; and, especially, scene after scene, and appeal after appeal, are poured forth in an uninterrupted shower of vehement interrogation.

Thus much must suffice for the contrast between Tropes and Figures. There is a little that may advantageously be remarked in regard to the various phases emerging under each of the two kinds separately.

As to Figures, their genuine differences of form are not many; and the simplicity of the law on which their effect rests makes most of those differences inessential. One distinction at least is worth recollecting.—There are figures which make no avowed appeal to sympathy; forms of speech which might find place in a soliloquy. Such are the Exclamation and the Apostrophe. These are favourite figures in the oratory of Chatham, of a man who, proud and self-reliant, though passionate, spoke as if to unload his heart of its burden of indignation and scorn, seldom as if

Processes
constituting
Eloquence.

caring even to awe his audience, and never with the air of condescending to conciliate them. Other figures are avowed appeals to sympathy; forms of speech applying dialogue. Here the great example is the Interrogation. This is the figure which, incalculably oftener than any other, is used by Demosthenes. By him his audience was never forgotten, never slighted: he is not satisfied with pouring out his flood of passion, leaving it to overflow where it might; he flings an image at them as if it were a boomerang, whose course is not finished till it has rebounded to the hand of the thrower.

Of Tropes, almost as provokingly as of figures, the theory has been hidden, by rhetoricians not looking deeper than the words, behind a thick curtain of nomenclature. The few names, which would have sufficed for denoting the natural kinds, they have treated as boys treat a little snow-ball, which they roll along the ground till it has grown too large to be moved farther. The winter's toy is melted by the first warm breath of spring; and the ventilation which some thinking introduces is, unluckily, enough to show that the cumbrous terminology which has been applied to tropical language contains few items useable in a rational theory of the mental character of tropes. But tropes have been treated, by not a few rhetorical writers, with great sagacity and good-sense. There is equal excellence of taste and of ability in this as in other parts of Irving's *Elements of Composition*, lately referred to; and Whately never fails to fortify his doctrines strongly against assaults from the practical side. For the tracing of tropes, however, to their mental sources, we have still nothing so instructive as the glimpses which were caught by the eye of Campbell, piercing forward with a wonderful instinctive acuteness from among the mists of a fragmentary psychology. A systematic survey of the differences among tropes, in respect both of their means and of their results, could hardly yield any classification of them more satisfactory than that which he proposed. "Tropes," says he, "are subservient to vivacity, by presenting to the mind some image, which, from the original principles of our nature, more strongly attaches the fancy than could have been done by the proper terms whose place they occupy. They produce this effect in these four cases: *First*, When they can aptly represent a species by an individual, or a genus by a species (the more general by the less general); *Secondly*, When they serve to fix the attention on the most interesting particular, or that with which the subject is most intimately connected; *Thirdly*, When they exhibit things intelligible by things sensible; *Fourthly*, When they suggest things lifeless by things animate." Let us see how this scheme may be fitted into the system of laws which it has here been sought to explain.

All tropes operate by substituting, in the first instance, the image of a secondary object for the image of the object which is primary. They become aids towards volition, as towards poetical pleasure, *either by vivifying the image or by intensifying the consequent emotion*: the secondary object either is imagined more vividly than the primary; or it is more interesting, more excitative of feeling. The choice of tropes depends on the question, whether it be to the image or to the emotion that we design to impart added strength.

Suppose it is desired to strengthen the Image. This is to be effected by raising the image of a secondary object which is more easily imaginable than the primary.—*First*, then, if we are confined in our selection to objects of the same great class,—phenomena of body or phenomena of mind,—we cannot aid the formation of the image unless by adopting the rule which directed us to substitute the less extensive term for the more extensive. When, in so doing, we descend only from one class-name or common term to another class-name which is narrower, we use one of the

Processes
constituting
Eloquence.

varieties of the trope which the old rhetoricians call Synecdoche. When we descend from a class-name to a singular term, the trope is an Antonomasia. In both cases the suggestive relation is coadjacence.—*Secondly*, if our primary object is a body or a corporeal phenomenon, we cannot facilitate the imagination of it by substituting a phenomenon of mind. But if our primary object is a fact of consciousness, it is in our power to facilitate the imagination of it immensely, by substituting for it an object corporeal. Our trope is one of the kinds of the Metaphor, and the prominent suggestive relation is Similarity; though undoubtedly, often or always, the chain has many intertwined links, some of which rest on coadjacence, and others on contrariety.—For Campbell's first class of tropes, and for his third, places have thus been found, as ministering to the strengthening of the image.

Again, let the design be to strengthen, not the image, but the Emotion. The method of doing so is the substitution of a secondary object which is more interesting than the primary.—*First*, accordingly, the nature of the case may shut out the possibility of exchange between mental states and things external. If so,—the primary object being always susceptible of dissection, either into parts simultaneously combined, or into changes happening in succession,—our course must be the selection of that element, factor, circumstance, which is more interesting than any other, and substituting the image of this for that of the complex object, whose complication had prevented this element from attracting exact attention. Causes and effects may thus be interchanged, things concomitant for each other, a part individually thinkable for the individual whole of which it is a constituent. Tropes of this flexible character embrace some varieties of the Synecdoche, with all the various kinds that have been clumsily ranged together under the name of Metonymy. The suggestive relation is coadjacence.—*Secondly*, A fact of consciousness would lose instead of gaining interest by having a corporeal object substituted for it. But, since a corporeal object really imbibes the whole of its emotive interest from its relation to mind, increased power of exciting emotion may and must be gained when an object of that first class is displaced in favour of an object belonging to the other. While a poet makes thought, and passion, and will more brilliantly imaginable for us, by clothing them in the shapes and colours of inanimate nature, he makes nature and externality the source of the profoundest feeling, and even the object of a fine ideal sympathy, by animating them with the life, and activity, and susceptibilities of mind. The latter is the higher and more refined process of the two: it reigns especially in our own recent poetry; the principle of it is the life-blood of fantasy to such poets as Wordsworth and Tennyson. The trope here is Metaphor; and the prominent suggestive relation is Similarity.—Campbell's second and fourth classes of tropes are thus placed together, as ministering to the strengthening of emotion.

(III.) LAWS OF MATTER.

Choice of
circumstances
tending to
excite volition.

31. In no application of persuasive eloquence, can a choice of objects be absolutely excluded. In the properly literary uses of the process the field of selection is almost unlimited: so is it in some departments not exclusively literary; as, for instance, the oratory of the pulpit. But there is room for adoption and rejection, even in those processes of communication, which have decisively a character of actual business dictating the outline of everything that is to be said. No fact whatever is simple; every fact which comes under practical discussion is in a high degree complex: every such fact may be presented in many different aspects; that is, through the exhibition of many different features from among those by which its totality is consti-

tuted. There is always scope for choice, therefore; though we look no further than to the event or other object through the desire or dislike of which it is attempted to arouse volition.

The boundaries of the ground are enlarged yet more, when we fall back on a distinction which has already been asserted to have a psychological basis. The completion of the process of persuasion,—the leading of others through wishing to volition,—involves consideration of other objects besides those which are to be the objects of desire or aversion. The attainment or prevention of these is the end: something else must be the means. In trying to persuade a man, we call his attention to at least two objects in succession: we invite him to desire the attainment of *a*; we invite him to believe that his doing the act *b* will be the means of the attainment; and therefore we invite him to desire (and will) *b* also. Thus even the direct (or immediate) objects are at least two: *a*, the end, the fact or event which is to be desired; *b*, the means, the act which is to be willed.

Nor is this all. If it were all, or nearly all, persuasion would be far from easy, perhaps; but it would not be the very difficult thing it often is. There will always be some other object. There may, and probably will be, many others, the exhibition of which is imperatively required for assistance in representing with due effect the desirability of the ultimate end, and the adequacy and possibility of the means.

There is, in short, a triplicity of complications. First, there is a complication of objects, as means, as ends, and as standing related to both. Next, there is a complication of processes: the imaginative representation, which is peculiar to persuasion, is mixed up with appeals to the judgment, either as exposition or as argumentation. Lastly, there is a complication of times as the sphere of the objects. Both the end and the means, the object of the desire and the object of the volition, are thought as future: the objects whose exhibition is required for setting those in their just light may range through all the modes of time; they may be future or present, but it will oftenest happen that most of them are things past.

It is well, therefore, to inquire, whether the principles which have yielded us a few subjective or formal laws of persuasion, may not, when viewed from the objective side, supply some corollaries having use as guides in the choice of matter. The questions thus arising could hardly be treated in a way better adapted for practical application, than that in which they are treated by Campbell. His classification of "the circumstances chiefly instrumental in operating on the passions," will be the groundwork of the very few doctrines that are now to be laid down.

The principles which should rule the choice of matter or objects adequate for direct persuasive representation, may be brought to a point in the following group of propositions.

The Emotive Interest, through which images presented by language prompt wish and will, must, in the *first* place, rest on the capacity of the objects to influence, favourably or unfavourably, the well-being of some conscious and sensitive being or beings. *Secondly*, the emotive interest is most intense, when the persons whom the objects are capable of affecting are the persons to whom the images are addressed, and when, therefore, the personal interest is Direct. In all other cases the personal interest is Indirect, arising through Sympathy; and sympathetic interest is strong in proportion to the closeness of the relations, between those to whom the images are addressed, and those on whom the capacity of influence bears. *Thirdly*, the objects must consequently be representable as events; and they must possess, in a higher or lower degree, two characteristics, which are conditions of the power of events to excite lively interest, whether direct or sympathetic. These character-

Processes
constituting
Eloquence.

Processes
constituting
Eloquence.

istics may be signified by the two words, Probability and Importance; and their nature may most easily be explained by negations. 1. The events must not be merely imaginary, and thus destitute of all bearing on volition: they must be capable of exciting a belief (stronger or weaker, but strong in proportion to the closeness of their relation to the volition which is aimed at), in their actuality, whether past, present, or future. 2. The events must not be purely trifling or insignificant; which they may be either on account of their own character and adjuncts, or (though more rarely) on account of the persons concerned in them: from the one reason or from the other, or from both, they must derive such an importance as shall at least be sufficient to excite attention.

Campbell's seven "emotive circumstances" are readily reducible under the heads thus set forth; and his analysis is so apt and useful, as to supersede the necessity for anything beyond a few hints in the way of illustration.

Evidently, the qualifications of emotive objects rise in efficacy according to the scale which our law indicates. Probability and importance are conditions, but conditions only: they have no proper causal efficiency. It may be objected, indeed, that we shall certainly be interested keenly, to the effect of wish at least if act and volition be impossible, by a momentous occurrence, positively known as affecting men many or distinguished. The answer to the objection is, that this is a sympathetic interest, for which the truth and importance of the event do no more than supply a groundwork. Equally clear is it, with no possible exception wide enough to qualify the practical uses of the law, that the strongest interest men in general can derive from sympathy, be their hearts as warm and expansive as they may, is feeble in comparison with that which inspires them in relation to their own happiness or misery.

The two conditions may reward a little attention.

The actuality of the event may be believed to be certain, morally or physically; but it cannot be emotive if the likelihood of it does not reach, at least, the low degree which is indicable by such a word as plausibility. It seems correct, also, to say, that the amount of likelihood which is the utmost attainable for an event contemplated as future, would be incalculably less effective if its object were a fact that is past, or one that is contemporaneous. The impression of probability to the extent which an individual case is thought to require, may evidently give occasion to the introduction of arguments, and will perhaps be, oftener than any other emergency, the adequate reason for such introduction. For the same end, the insinuation of belief through plausible exposition may be, and often is, singularly effective. If we had time to turn aside, and glance at the bearings (for there are many such) of these doctrines on poetry, this question might be put:—Whether the undisguised allegory, which falls on most readers with so dead a coldness, is not stopped at the very first stage of its passage towards emotive excitement, by the initial impression it makes of an unreality which we cannot even fancy to be removed?

As to the second condition, one remark only is needed. There is frequent risk that those whom we desire to interest in an event, may think it to be, both in its own nature and in respect of its causes and consequences, so unimportant, that their attention can hardly be awakened to the imagination of it by any considerations of this sort. But, unless they are unusually low in the scale either of intelligence or of susceptibility, they can scarcely fail to take some sympathetic interest in any event which is known to be actual, and which affects any human being whatever. Towards keenness of interest, however, especially in the absence of personal relation, the importance of the persons having part in the event is a very active instrument of excitement.

The last four of Campbell's emotive circumstances are reducible to one principle, by a generalization to which he

himself shows the way; and the taking of one or two subordinate distinctions suffices to systematize completely this part of his scheme.—Sympathetic interest, which it is or ought to be experienced by us towards all men, is quickened in a geometrical ratio as its sphere of objects is narrowed, in convergence towards the circle within which our personal affections revolve. Circumstances which imply such an approach are actively suggestive to us of reflections, which give to these an indirect power of excitement. Such circumstances are, first, proximity of events in time; and, secondly, proximity of events in place. It must be a question dependent on the concomitant features of a case, which of the two shall be the more strongly emotive. But both the one and the other move us, not otherwise than by suggesting the relations on which emotion generative of desire must directly rest; and the representation of an event in which such relations are explicitly prominent, must always be more effective than any indirect method of excitation. We are moved intensely by events concerning those who stand in close relation with ourselves; and, while benevolent and sympathetic affections may, in some finely-touched natures, be even more profound than those which centre in self; so, for fiery and angry tempers, or in circumstances which keenly irritate even tempers less harsh or hasty, hatred and revenge may for a time quite overpower regard for self. But, in all ordinary instances, the objects most excitative of desire or aversion, and of volition if action be possible, are undoubtedly events with whose progress and consequences our own happiness or suffering is known by us to be connected.

(IV.) SUPPLEMENTARY QUESTIONS.

32. There come up for consideration, lastly, two questions, which, though they involve form, involve matter also, and which therefore could not aptly have been raised earlier. *In the first place*, persuasion, like argumentation, may be attempted, not on minds open to its influence, but on minds prepossessed against it. How, then, if at all, by means different from argument, may emotions be got rid of, which would prevent the rise of the desire or volition aimed at? *In the next place*, although eloquence is not poetry, nor poetry eloquence, yet each of them has in it so many of the elements of the other that their results must sometimes coincide. Poetry has not infrequently been made the spur to action: persuasive eloquence has always been held to be, in some degree or other, amenable to the laws of beauty or taste. What can be determined as to the admissibility, into persuasion, of that imaginative pleasure, not tending towards action, the excitement of which is characteristic of poetry? A question nearly allied is this other: What place is there in eloquence for appeals to the sense of the ludicrous, through wit and humour?

The answer to the first of these questions may be given in the following shape. The answer to the second will follow in the next section.

I. For the removal of Emotions Unfavourable to the excitement of the wish and volition, which in a given case persuasion aims at, the methods most widely available are three.—*First*, The allaying of the emotion may be attempted, by the representation of the object in an aspect which does not tend to excite the unfavourable emotion, and the contemplation of which, therefore, is inconsistent with the continued intensity of the emotion. *Secondly*, The diversion of the emotion may be attempted, by the representation of some other object, which tends to excite the unfavourable emotion, and on which, therefore, it may be expended harmlessly. *Thirdly*, The extinguishing of the emotion may be attempted, by the representation of the object in an aspect tending to excite some other emotion, irreconcilable with the emotion which is to be removed.

Processes
constituting
Eloquence.

Removal
of unfavourable
emotions.

Processes
constituting
Eloquence.

The three methods which have thus been described rest obviously on the same principle. The mind can never be totally blank; and in those changes whose agitation is the life of consciousness, emotion in some phase or other wells up incessantly to the surface. All the methods, therefore, are designed for converting the obstructive emotion into an emotion which shall not obstruct.—The emotion may cease to obstruct, if its intensity is diminished so far that it no longer prompts any wish at all; and here will emerge scope for argumentation, as in proof of improbability, insignificance, or want of real personal relation.—Again, the emotion may cease to obstruct, if there be suggested some other object of thought, which indeed keeps the emotion awake, but the character of which is such that the emotion or consequent wish bearing on it shall not be incongruous with the emotion and wish to which the persuasive process is directed. When dislike is felt towards a person in whose behalf we intercede, a hearing may be found for our words in his favour, if he ceases, though it were but for a short while, to be thought of as the object of the grudge, some other victim being suggested who as well deserves it.—Lastly, the emotion which is obnoxious may lose its hurtfulness, if there can be conjured up some other emotion, incompatible with the continued existence of it and its volitional consequents. This declaration of open war against an impeding emotion or desire, is more frequently called for and more extensively possible than either of the other methods of attack; but in a majority of cases it cannot be brought to bear, unless through and after processes of exposition or argumentation. The most signal of its occasions are ministered by the diversity, and the frequent incompatibility, of the relations in which every man stands towards every object which he can think of as attainable through exertions of his own. Hardly anything is there that can seem desirable to us as giving free play to some strong law of our nature, but the thought will arise, that the gratification of that desire would be attended with the pain consequent on disobedience to some other law. Well is it for us when deliberation is prompt and firm, and when choice is guided by wise and worthy motives. When there is doubt, and especially when that doubt is deeply founded, either on the character of the objects or on internal weakness of our own, the door is open for the entrance of influences from without, which may determine us with momentous effect either towards good or towards evil. Among such influences, powerful eloquence may be one of the most active. We have brooded longingly over a future act, which promises to gratify avarice, or hate, or ambition: our inclination towards it may be cooled or extinguished, by a startling representation of the gnawing pain of the remorse by which one day it would surely be followed; and our imagination may then be sensitive to the image of some other act, some act of forgiveness or self-sacrifice, which, in satisfying conscience and the love owing by man to man, would bestow the purest and highest happiness that can spring from within, but which, as being adverse to our preconceived passion, we could not bear to contemplate till that passion had been made to die away. Unfortunately, likewise, the progress might be in the opposite direction: we might be made to sink from the nourishment of a wish virtuously and nobly prompted, to the displacement of it by another, derived from mean and degrading sources of enjoyment. One of the most obvious, as well as most usually employed, of the antitheses which give room for such diversions of emotion and desire, is that which subsists between the serious and the ludicrous. Put the case, that the obstacle which bars our being led towards a certain wish or the consequent act, is our fear or our hatred of a person who would be benefited by it. It could rarely be possible, by force of mere words, whether argumentative or imaginative, to convert our ill-will directly

into any benevolent affection. But even so, the ill-will might be rendered inoperative through feelings which, though still prompted by a bad opinion of the person, could not co-exist with our original desire of injuring or resisting him. If a man is simply ridiculous, if our feeling towards him is mere contempt, we cannot hate him cordially, and shall not fear him at all. This case,—the diversion of emotion and wish of a serious cast by the exhibition of the object in an aspect which is ludicrous,—introduces us to the second of the questions raised in the beginning of this section. For wit and humour rest on the emotion of the ludicrous; and they stand in relations which, though far from being clear, are very intimate, to the imaginative pleasure which is characteristic of poetry.

Processes
constituting
Eloquence.

33. II. That Imaginative Pleasure, the excitement of which is the characteristic function of poetry, is so far in- as to the consistent with the kind of emotion which issues in volition, and the objects tending to excite these severally are in the most instances so unlike each other, that emotions of the former class cannot in a process of persuasion be excited either intensely or very frequently, without difficulty, or without some risk of injury to the persuasive result. The emotion of the ludicrous, also, as excited by Wit and Humour, is indeed, oftener than purely poetical pleasure, excitable by objects available towards persuasion; but it likewise is equivocal in its effects, as not tending directly towards action. Nevertheless, both pure poetical pleasure, and the emotions excited by wit and humour, are often useable with advantage in persuasion, under the restriction always of being kept in subservience to the distinctive purpose of the process. Especially it is true, that the slight or moderate excitement of a pleasure properly poetical or contemplative, not only is often a natural consequent of the contemplation of objects tending principally towards the excitement of volition, but is even a condition towards the full effect of persuasive eloquence in a cultivated and refined state of society.

That, even in processes aiming at the purposes which constitute the distinctive province of eloquence, there is scope for the entertainment of the purpose which distinguishes poetry,—is a proposition, the truth of which is allowed, by implication, in doctrines which have a place, and which, being important as well as true, deserve to have a place, in every intelligent code of laws ever laid down to guide the student of rhetoric. No reasonable doubt can be thrown on the assertion, that certain elements truly poetical are admissible in eloquence as subordinate adjuncts and decorations. But difficulties begin to gather about us, like thickening mists, when we strive to determine analytically the relations between the means which subserve the poetical purpose, and those which subserve the persuasive,—and when we seek to derive hence a code of exact restrictions.

Such a code would bridge over, for passage from either side, the gap on whose opposite sides poetry and eloquence stand, covering ground which exhibits dissimilar landscapes, but which hides strata illustrative of analogous formation. The piers of the bridge, however, must be two: a theory of eloquence, a theory of poetry. For the former of these, there is given here no more than a plan; and the attempt even to design the latter, is forbidden alike by the purpose of the treatise and by its limits. We can venture on nothing beyond some hasty strokes, indicating a very few features, in respect of which the two classes of processes are least likely to conflict with each other.

It is in effect acknowledged by rhetoricians, that the effectiveness of eloquence is impaired, if not destroyed, by the intrusion of anything excitatory of emotions contradictory of those which it is the prerogative of poetry to excite. For so much must be meant by the maxim, that neither in

poetical
pleasure.

Processes
constituting
Eloquence.

persuasion, nor even in argumentation, should there be admitted any object, or any treatment of any object, which would offend against the laws of taste. The rule is sound for any discourse intended to possess a character properly literary; that is, it is sound for the highest and worthiest class of cases to which rhetorical precepts are applicable. Though, likewise, taste should be understood as meaning good taste, the rule would continue to be sound for all discourses whose hearers or readers possess a reasonable amount of æsthetic cultivation. If the proviso be interpolated, that the taste of the audience, be it good or bad, is to give the standard, the rule holds for all cases possible. Every man is in some degree susceptible of a contemplative pleasure, incident to the exercise of his imagination; however widely the objects exciting that pleasure in a rude and coarse mind may differ from those which would excite it in a mind refined by nature and by training. And no man can fail to be interrupted in his progress towards belief and desire, if the object be set before him in a light which, independently of relations to action, affects him with an unpleasant feeling. So much is admitted when the question is considered from the negative side.

A positive rhetorical value is attached to poetical pleasure, in rules commonly laid down for style. Obedience to the laws of good taste is prescribed to language: it should, we are told, possess the quality called Beauty or Elegance. The rule is good for every composition of a class worthy of being criticised, and for every writer or speaker who is likely to reflect on his task in a thoughtful spirit. It is an instructive fact, however, that no one has ever been able to describe intelligibly any specific method (beyond rules properly grammatical) of putting the maxim in practice. The student of eloquence can only be told that, rules which bear on or tend towards Perspicuity being duly attended to, he will approach towards eloquence of style in proportion to his success in making his style Animated,—that is, in fitting it for the purpose of persuasion. The study of language is often helpful towards the excitement of imagination and of some consequent emotion; but what the character of that emotion is to be, is a question dependent, not on the words, but on the matter.

We reach higher ground on the positive side,—indeed we gain a rule which is practically more useful than any other relating to this question,—when we take account of a doctrine on which great stress has been placed in several preceding stages of our survey. In no use to which language can be put, is any quality of a composition more valuable than its power of commanding attention. Now Attention is excited by everything that is emotive. It is a question not always met by one answer,—which of the two shall arouse attention most effectively; an object moving us to pain, or one moving us to pleasure. So likewise, a positive answer could not be given to this other question:—whether attention will be attracted most keenly by an object raising feelings which prompt towards action, or by one which raises feelings not having that tendency. The chances are much in favour of objects urging us towards desire and will; and, for reasons lying in the same quarter, the chance is also, that attention will be more keenly awakened by painful objects than by pleasant ones. So much the less danger is there, that objects such or so represented as to incline by both paths in the opposite direction,—that is, away from action and away from pain,—should, if they are suggested sparingly, interpose any serious check or wide diversion to the course into which persuasion aims at inviting the mind. Therefore, far from seldom, when both theme and audience are favourable to the finer influences, persuasive eloquence may warrantably seek to awaken or enliven or revive attention, through images which do not immediately lead beyond the play of fancy and the pleasure which is attendant on it. When, indeed, the use of such expedients is

VOL. XIX.

guided by genius and skill, the excitements of the poetic or semi-poetic vision and emotion may be gathered from among the adjuncts of the very object on which action is to be directed; the transitory change of mood, too, is not unlikely to allow the gathering of new energy of consciousness; and the check which for a moment threw the wave of feeling backward upon thought, may give even a fiercer impulse to the gush with which afterwards it plunges forward into passion.

34. The legitimacy of the poetical element as an aid to The relation between persuasion and poetical representation. The eloquence, not only as a powerful means of calling up attention, but also as a direct step on the way towards the end aimed at by persuasion, will be put on a ground yet broader, and may perhaps be extended to more various applicabilities, through the answer which may correctly be given to a question now to be put.

Poetry and Persuasive Eloquence pursue for a certain distance the very same track: at what point do their routes necessarily diverge? More specially, they concur in working through the excitement of Imagination and consequent Emotion; persuasion, however, must have as its next step the excitement of a Wish, whether it be a desire or an aversion: must it be held, then, that poetry cannot take this step,—that it would be unfaithful to its function if it should excite the Wish that something were, or that something were not? The answer is this. It is not true that the excitement of desire, or even of its contrary, is excluded from the competency of poetry. Such an exclusion is quite inconsistent with all ordinary opinions; and it is very far indeed from being a necessary consequence of that exact separation between poetic and persuasive representation, which it has here been attempted to illustrate. The bearings of the question could not be set forth satisfactorily, without a full exposition of the theory of poetry which is now founded on; but a few hints, merely fitting along the edge of one section in that theory, will exhibit some of the data on which the answer must depend.

Contrast, first of all, a poet's warm description of poetry with the colder one given by a philosopher. Let us think especially of the third quality assigned to poetry, in those pregnant words of Milton, seized on admiringly by Coleridge. "Poetry," says he, "is simple, sensuous, *passionate*." Kant, on the other hand, asserts of the Beautiful, that it is "*without interest*;" and with him, as with most or all of the more recent Germans, all the emotions characteristic of poetry and the other fine arts are emotions of beauty. The two doctrines are quite reconcilable; but both require some explanation.

It must be maintained firmly, as the central doctrine of all the fine arts,—that, while their mode of operation is the excitement of imagination, their end, the result for the sake of which the operation is performed, is the excitement of Emotion, of a state of mind which is a feeling. If it is admitted that their end is pleasure, this is accepting the doctrine, only specifying it (and correctly) by saying that the emotion is pleasing. If the mental process which it excites shall travel onward even by one step further, in that normal development of consciousness which issues in action, the art has, in its result (which presumably is due to something in its procedure), trespassed on ground which it cannot continue to occupy without becoming an alien to its native domain. But if it has taken the one step only, its position is easily recoverable: the wish, the desire, the longing, may generate only a new emotion, purely contemplative; and,—such flowings and ebbings being successively prompted through successive images, whether suggested by the poem or by the fancy of the reader,—wish and emotion may float through the soul in a series of delightful alternations, each impelled and guided by some

quence.

new image in the thronging train of airy fantasies. None of the emotions can be more than momentary: no emotion can be more. But it is for the sake of the emotion that the images and wishes are cherished; and, so long as the poetical mood endures, it is back into emotion that wish and image will incessantly fall. That which would most effectually annihilate the poetical mood, that which most certainly would make the mind cease to be susceptible of the visionary emotion, would be the development of the wish into a consequent volition. The calm lake which has been darkened by a passing cloud, becomes again the mirror of its woody bank as soon as the sunshine again breaks out; but when the mountain blast has swept over it, its surface, lashed into agitation, can no longer reflect the brilliant shadow. This, then, is what must not happen as the effect of poetry; the transformation of desire into will. If such a transformation should take place incidentally, the mind which is the subject of it has been thrown down into a mood which is anti-poetical, and from which it cannot easily be elevated by the purest poetry which may next be presented to it. If a work poetical in name aims at such a transformation, it is really not a poem, but something else: with the introduction of such a design, it has ceased to be poetical, and has become persuasive. Understood under these explanations, Kant's proposition may be accepted as equally true and important.

Not less important are doctrines, which may be supposed to have been intended under the proposition which was quoted as its counterpart. Towards that one among those doctrines which here concerns us, the way has been opened by the assertion, that the transition from emotion to desire is not necessarily destructive of poetical effect. This assertion is not broad enough; for, though it is true, it contains scarcely half of the truth. Not only is it true that poetry may prompt wishes without being faithless to its vocation: it is true, moreover, that poetry does and must incessantly prompt wishes in all their higher modes,—as good-will or ill-will to persons, or as inclination or dislike to states of our own, dependent on things. It is equally a truth, and is a truth still more momentous, that to its capacity as a prompter of wishes poetry owes the possession of powers, the loss of which would degrade it into a mere toy, the plaything of a few imaginative dreamers. That capacity is not what makes poetry to be poetry: it is not what makes any fine art to be a fine art. But so far as any fine art can exercise that capacity without impairing its own peculiar functions, just by so far is that art elevated above being a mere decoration of life and a mere pastime for leisure; the comparative freedom with which that capacity can be subordinated to poetical ends, is the most active of the causes which raise poetry immeasurably higher than any other of the fine arts; and the fulness of diversified suggestion with which, through that capacity, poetry can people the visionary land conjured up by its spell, is the fountain whence flow out the love and reverence with which poetical art is honoured by the universal human heart. That which confers the capacity is the symbolism of language. By the manner in which words operate, arts making them its vehicle are, as we have seen, shut out from certain modes of representation which are open to arts operating directly through perception. But, in their own manner, through symbolic suggestion, words can represent all conceivable objects. Therefore poetry embraces, in its light but vigorous grasp, all those classes of objects, to one of which separately each of the weaker fine arts has its province confined; therefore also poetry enters into sympathizing alliance with those processes of real life and action, most of which the other fine arts have neither hand to touch nor eye to see.

If we are to use the term Beauty as designative of objects which excite the pure emotion of contemplative art,

whatever be the kind of process by which the emotion is awakened, the ordinary and obvious meaning of the word must receive a very large widening. That which we should naturally speak of as beautiful is an object of sight. Pleasing colour, or combinations of colour, may indeed be disposed of rightly by being regarded as no more than precedent conditions, and described as sensuously agreeable; and, when this exclusion has been made, Beauty proper is beauty of form. The arts of design are the only fine arts whose works are beautiful in this sense. Even such a work is not high in its class, unless the form which it presents and suggests shall to Beauty add what is usually called Expression,—that is, the capacity of suggesting emotions tending towards wish. Whether beauty of form is possible in the absence of expression, is a question which, though the answer is not far to seek, cannot be touched at present. The two antithetical terms do, at least, denote the predominance of the one or the other of two diverse attributes. The law of those arts might thus be said to be, that beauty shall predominate over expression; intensity and fulness of expression enliven and elevate a picture or a statue, but expose it to the risk of overstepping its proper function. Now, poetry has doubtless the power to suggest images of beautiful forms. Not only, however, is the suggestion vague, the same words exciting different images in every two different minds; but, over and above, it subserves in no more than a very slight degree the poetical effect. If beauty is beauty of form, the law of poetry is not beauty, but expression.

It is desirable, however, that we should be able to designate by one common name all phases of the pure contemplative emotion characteristic of all the fine arts; and the word Beauty, originally given to sensuous agreeableness, and raised in the language of art to denote attributes of form, offers itself temptingly for use. Of all objects excitative of pure poetical emotion, it is convenient to say that they are Beautiful; and it may not be unsafe to call them so, if we can guarantee our steady remembrance of the fact, that their beauty is Expressive Beauty. The necessity for implication of the limiting epithet reminds us at once of the world-wide sphere of poetical objects, and of that tendency to put the objects to extraneous uses by which poetry is beset more than any other art of its class.

Terms being thus understood, Expressive Beauty might be said to be the central law of poetry. Pure poetical pleasure is generated by images which, whether they be pictures of nature or of life, or of human consciousness as it works within, are barred by their ideal character from all immediate bearing, not only on action, but even on wishes tending to action, either of our own or of others. The glittering shower of fancies, and feelings, and longings, which the fountain throws up, cannot flow outward to form a brook, but incessantly, in sunshine and music, falls back into the encircling basin. Poetry having no other elements than these, would be pure; but it would not be strong. It would be lyrical in spirit, whatever it might be in form; and much more is demanded of it. If the poet would stir up the heart from its depths, he must look abroad on life, and feel the passions of humanity: he must conjure into the circle of his art shapes expressive of the purest joy, and the deepest suffering, and the most energetic action; that, by sympathy, and hope, and fear, the atmosphere may be agitated into healthy circulation.

Thus, from the heart of its empire, where it would only be a sluggard-king dreaming on his day-bed, Poetry, justly desiring active rule, and sometimes imprudently ambitious of foreign conquest, travels outwards towards or up to the frontiers of its dominions, and that by any of many diverging paths. In every direction, as the distance increases, the operation of the central laws becomes weaker,

quence.

Processes
constituting
Eloquence.

though spontaneous activity is developed more and more energetically; and, if the borders are fairly crossed, the laws of the poetical realm cannot be enforced, unless as an invader might impose on the conquered any laws he chooses to bring with him.

When we remember that the sway of eloquence stretches over all those contiguous territories which poetry is so often tempted to reconnoitre or to visit, it becomes plain that the two are actually connected by bonds much stronger than those which show themselves on the surface. If poetry, by drawing closer its relations with life and action, can often inspire itself with increased force and profundity of passion; so eloquence may, though seldomer and with less safety, rise to higher refinement and elevation without essential loss of strength, through idealization of imagery, and consequent softening of desire and emotion.

Poetry seeks its frontiers by two high roads, leading in directions diametrically opposite. The one of these, pointing as it were to the cold north, soon enters desert tracts, and has few by-paths worth traversing: the other ushers us into scenes where everything around is full of warm interest and overflowing with luxuriant activity. In the first of those quarters the principle of animation is the emotion of the Ludicrous. When objects capable of exciting this feeling are contemplated from those idealized points of view which exclude immediate reference to action, they yield images whose æsthetical character is describable by such names as Wit and Humour; the former of which may be said to have its objective root in incongruity of ideas, the other in the incongruities of human nature. It is so difficult to reconcile feelings of this class with loftier and more worthy aspirations, that the excitement of them is hardly admitted in any of the fine arts, except painting and poetry; while even in poetry their sphere is narrow, in comparison at least with that which belongs to serious emotion. In eloquence, they have a scope which is very much wider; and, when the character of the matter and purpose does allow either persuasion or argumentation to call in the aid of the ludicrous, the circumstances always allow, and often require for the production of full effect, that the representation be idealized or æsthetically softened in such a way as to make it rightly describable as witty or humorous. It is on this side, indeed, that eloquence, though coming in contact only with one small frontier-province of poetry, touches the poetical domain more closely than it can on the opposite or serious side.

On this other side, poetry seeks to gather materials out of all phases and all degrees of serious emotion and passion, and desire and aversion. The kinds of the objects are not more diverse than the uses to which the art strives to put them. Milton's phrase, already used, may be understood widely enough to cover all varieties of the applications, to which poetry thus seeks to put the seriously emotive relations of life and action. Let us say that poetry, when it shoots off at this pole from the sphere of the purely Beautiful, passes into that of the Passionate. We come nearer to some of the problems which the name suggests, by saying that the genera of the passionate are reducible to two: the Sublime, which tends towards development in the Epic; the Pathetic, whose characteristic development takes place in Tragedy.—In the Sublime, the predominant emotion may be said to be an idealized modification of Fear. Being so modified by being taken out of immediate relation to action, and being modified further by specific characteristics of the objects (which affect variously both its kind and the degree of its intensity), fear becomes the kernel of emotions to which perhaps all branches of the sublime may be referred—Awe, Reverence, Wonder. If the objects, as real, tend to excite emotions justly describable by such names, it must be the fault of the poet if the same

emotions are not excitable by the poetical representation of them. But genius and skill of art may purify into those phases the impressions made by objects, which, in the reality, would be merely terrific or horrible; while, contrariwise, whatever be the character of the objects, want of skill or coarseness of feeling in the poet may throw a work, or a scene or image of it, out of the true province of poetry, by giving predominance to the unidealized phases of the emotions.—To the Pathetic, as a variety of the passionate, would be referable all cases in which the emotion, whatever be its kind, is aroused, not directly, but through Sympathy. Sympathetic emotion, imaginatively reflected or thrown back, falls into modifications of poetic emotion, which, though by no means the only modifications that may be called tragic, are those on which Tragedy is dependent oftener and more widely than on any others.—If the pathetic should rise so that it seems to merge in the sublime, there is still this ground for a separation such as that which has been hinted at, that the emotion of sublimity generated through sympathy remains relative or subjective, while there is another region of the sublime in which emotion is excited directly,—that is, through thought in which the prominent idea is that of the object.

35. The applicabilities of those distinctions to rhetorical use can be but very rapidly touched on.

In the first place, the idealization of passion has an incidental and subsidiary use, which, though it cannot penetrate deeply into the matter principally treated, stretches over almost all kinds of composition that are not poetical in design. It is often an apt means of awakening or enlivening attention. Pleasure of any kind, and imaginative pleasure not least, inclines us to concentrate our thoughts on the objects that excite us; and the inclination is suggestively transferable to objects with which those others are in relation. Though the staple of a discourse should be severe abstract reasoning, the mental eye may the more promptly admit the clear and cold light of truth, if it has been strengthened and excited by semi-poetic fancies flickering on the distant horizon. On occasions not a few, likewise, ideal imagery acts in the same direction, not only in virtue of its own force, but also by raising prepossessions in favour of the mind from which it springs.

Questions more doubtful confront us when we come to consider specific adaptations, involving cases in which the poetic mood might become a prominent feature in the mental state excited.

The most delicate of all cases, is that of a discourse designed for carrying on the process of persuasion to its consummation. Such a discourse must have a practical bearing so immediate, that hazard would almost always be incurred by any aspiration rising, for more than a very brief flight, above the level of actuality. Equally practical in effect, and therefore equally intolerant of invitations towards the contemplative, are most of those discourses in which, though the persuasive process in its earlier stages holds a conspicuous place, still it is really no more than subsidiary, the purpose ultimately striven after being the generation of belief, the enforcing on an audience acquiescence in the truth of a proposition. In describing such instances, however, we are taking it for granted, not only that the occasion is in substance a matter of active business, but also that the effect on the recipients, be it what it may, is designed to be immediate. But if judicial oratory be held to fall within this description, with some applications (certainly not all) of oratory to political and other social questions, we are yet entitled to say that there are many other cases, still oratorical rather than strictly literary, in which the design is different, and the field raised more or less above that of every-day life. Especially, it happens very often, as in many discourses of a religious cast, that

applicabi-
lities of the
doctrines
last set
forth.

Processes
constituting
Eloquence.

the end looked to lies beyond any mental state that is excited at the moment. What is wished for is the excitement of such a frame of mind as shall prompt subsequent thought; so that, though volition should be the result ultimately in view, it shall only spring up hereafter, seemingly from the spontaneous action of the resolving mind, but really from germs which have been sown by the speaker. The ground is thus enlarged on all sides; and passionate poetry surrenders many a spoil to the successful forays of passionate eloquence, provided always the objects be such that each of the arts may, in its own way, handle them to advantage. It is, however, when the poetic voice is but imperfectly modulated that oratory may most freely emulate its tones. Eloquence of all kinds, indeed, speedily grows languid in the rarefied atmosphere which fans the serenely sensitive existence of the highest poetical art: if its breathing is to be free and its action energetic, it must not climb above those subalpine heights, on which the dense air of real life has been relieved but in a slight degree from the superincumbent pressure.

But, further, though the spirit of these restrictive cautions must guide us everywhere, yet the quarter on which they tell most strongly fills a space comparatively narrow in that large territory, which is here claimed for Eloquence and alleged to be subject to its laws. The mass of pure literature is made up of works which owe their literary character, not to circumstances raising them above the occasion that prompted them, but to the intention with which they were brought into existence. Those works are not intended for generating one immediate effect,—not for producing one state of mind, which both has little complexity, and is concentrated on one group of objects. They are designed for producing a series of mental states, which shall expatiate over many and diverse objects presented in succession; and they are designed for producing those states through deliberate study, in which the reader's thought works with an independent activity, marvellously unlike the receptive obedience with which the same mind would have been impelled to follow the same prompting if it had been pressed with the hurry and force of oral declamation.

All such works issue, as it was asserted in one of the prefatory sections, from a combination of more than one of the three elementary and normal processes, and most of them from a combination of all the three. It must carefully be remembered, too, that, in instances which occur continually, each of these processes is performed in part only; there is a turning off from the road after the earlier stages of the journey. In the appeal to the judgment, the end desired may be, not to establish belief, but only to prepare the way for it: thus exposition may go no further than analysis of ideas or explanation of words; and the occasion may entitle argumentation to rest in the suggestion of conjectures. Still more frequent, and more frequent in pure literature than in oratory, is the occurrence of a process, in which persuasion, used only as an aid, is satisfied with the conjuring up of emotive images, or, at furthest, stops short with the raising of vague desires. History, for instance, and its hand-maid Biography, are essentially expository. But in these kinds of composition there is no phase of eloquence that may not co-operate with the main purpose, from the passionate picturing of characters and events, to the calm inculcation of universal truth. Nor would it be either just or safe to pronounce sentence of outlawry on certain branches of prose literature, which dwell so temptingly on the very borders, that they themselves are often doubtful to which of the two kingdoms their allegiance is preferably due. The novel and romance should be dealt with on this footing; that they are works essentially poetical in design, but sacrificing purity and elevation of æsthetic effect to the interest and variety of a biographical kind of individualization, for which verse would not allow scope. Many other kinds of literary works we have,

Processes
constituting
Eloquence.

and some of these interesting and brilliant in a high degree, to which there must be extended a tolerance still more liberal, yet not so liberal as to absolve them from all obedience to law. In such works the writer is content with his position as the man of genius, without claiming also the rank of a literary artist: he casts forth, because he chooses to do so, the products of his vigorous reason, or rich imagination, or profound sensibility, without seeming to aspire to the production of any one class of effects, and perhaps without conjecturing or caring what might be the issue.

Evidently, even in those legitimate forms of literature in which unity or totality of effect is firmly kept in view, there is thus room for such a diversifying of the means of impression as to preclude the possibility of passive subjection to any specific code of laws. But, while every literary free-man resists to the death the fetters which pedantic rules would rivet on him, no literary man can scorn with impunity the constitutional code of that realm of thought, in which, by attempting literary creation, he enrols himself as a citizen.

Those assertions must be repeated which were our point of departure. The distinct conception of one paramount purpose is the root of everything that is really great and strong in any department of literary art. The only purposes towards which literature can intelligently work are those which have now been recognised. The processes which have been represented as leading severally to the attainment of those purposes are the norms of all literary methods. Genius can, in a certain degree, achieve success in spite of itself; it can force its way in defiance of obstacles which it has reared up in its own path: vigour of thought, of imagination, or of passion, can bear receptive minds along with it, though its procedure should be incoherent; and to kindred souls it can suggest results possessing a symmetry which it had itself inadequately conceived. But the finest or loftiest genius can give birth to no work of art which shall be either great or enduring, unless it has learned, from reflection or from instinct, the few broad principles on which the character of art depends. Laws which are rooted in the nature of things never fail to avenge themselves on those who disobey them.

APPENDIX.

THE LAWS OF PROSE STYLE.

36. Questions of Style, which are the prominent feature in many systems of rhetoric, and the whole contents of many others, have with us been made to stand far in the background. This is thought to be the place which becomes them. That characteristic manner of expression, which is what we understand by the style peculiar to a writer or speaker, may indeed have derived some of its points from the study of models or of rules; but it is determined mainly by the cast of the man's own intellect and character, and is really peculiar or forcible in proportion to the amount in which he possesses individual peculiarity or strength.

A general theory of communication can fitly consider this question only:—what qualities must not be wanting in language if the style constituted by the words is to be good,—that is, if it is to be fit for serving the uses to which language is put? Adequate knowledge both of things and names being presupposed, this answer is given:—that style cannot be good unless it obeys laws belonging to each of two several orders.—In the first place, there are laws, disobedience to which, if thorough-going, makes language unfit to be a medium of communication for any purpose whatever. These laws constitute the science of Grammar; and, in fact, a very large proportion of the rules laid down for style are grammatical, not rhetorical. These are the most workable of all rules of style; and they cannot be too

Outline of
the prin-
ciples rul-
ing prose
style.

Processes
constituting
Eloquence.

sedulously attended to by the unpractised student of composition.—In the second place, there are laws, disobedience to which unfits language only for some one purpose, leaving it (under limitations to be marked immediately) available for purposes which are different. These are the only laws of style that are properly rhetorical; but they are nothing else than the laws of the processes of communication we have already studied, or corollaries drawn from those laws by the easiest deduction. They have been brought out already in illustration of the theory of the processes, at all points where they aptly served that use, and were not too obvious to deserve being explicitly stated.

It may be well, however, to draw together under one outline a digested sketch of the principles of both kinds, within which must fall all specific Rules of Style. Poetical composition, which commonly and most wisely adopts metrical forms, is beyond our purview; and, for the purposes entertained by eloquence, the words may be held to be always couched in the form of prose.

I. The Purposes of language being *three*, and none of the three being absolutely excluded from the competency of eloquence, Prose Language, if it is to be fit for the attainment of all the three, must have each of three specific aptitudes. It is fitted for each of the three purposes by a combination of certain qualities; and each of the combinations receives one name. It is fitted for the purpose entertained in exposition and argumentation by Perspicuity; it is fitted for the purpose entertained in persuasion by Animation or Vivacity; it is fitted for the purpose entertained in poetical representation by Beauty or Elegance.

Language is said to be Perspicuous,—or adequate for communicating cognition or thought,—when it is free from each of three faults. It must not be obscure,—that is, convey no meaning clearly; it must not be ambiguous,—that is, convey more meanings than one; it must not be unintelligible,—that is, convey no meaning at all. But language has not the degree of perspicuity it ought to have, unless it conveys its one meaning readily as well as clearly.

Language is said to be Animated, when it is adequate for the purpose of persuasion. But the only element of this adequacy for which rules of style can give any assistance, is, or arises directly out of, the special aptitude of the words for exciting Imagination, the first step in the process.

Language is said to be Elegant or Beautiful, when it gratifies the taste,—that is, excites imaginative pleasure. In respect of the words, this gratification stands yet more closely related to persuasion than it does in respect of the objects and their images.

II. Although each of these three names denotes a specific aptitude for one purpose, yet the relations which connect the purposes cause the second aptitude to be dependent on the first, and the third to be dependent both on the first and on the second. Language may be perspicuous without being more: but it cannot be animated without being perspicuous; and it cannot rightly be said to be elegant unless it be both perspicuous and animated.

Hence perspicuity is an *essential* quality of style: it can never be dispensed with. The other two are *occasional* qualities. In certain kinds of composition they would be out of place; in other kinds, they might safely be wanting; and they might be absent in certain parts of compositions which elsewhere admit or require them.

While, again, animation is dependent on perspicuity; so, contrariwise, animation increases perspicuity in certain cases, and lessens it in others. It increases perspicuity when, by aiding in the excitement of imagination, it makes attention more energetic. It lessens perspicuity when (as in philosophical or other abstract discussions), the ideas requiring very wide terms for their full expression, the desire of animation leads to the use of terms which are too narrow.

Processes
constituting
Eloquence.

III. For the attainment of Perspicuity, Animation, and Elegance, severally, language must be brought to bear on the specific purpose in respect of three parts:—the Choice of Words or Phrases, the Number of them, the Putting Together of them.

1. (i.) So far as the Choice of words and phrases is concerned, language is made Perspicuous by its possession of two qualities: Purity and Precision. The former consists in conformity to grammatical laws, which fits the words for conveying some meaning; the latter consists in conformity to the thought of the speaker or writer, which fits the words for conveying the meaning intended. When the choice is spoken of as embracing phrases as well as single words, there is designed such a description of this one element of perspicuity as shall enable it to cover all questions purely grammatical. Purity, then, grammatical correctness, is, within certain limits (which it is never worth while to transgress), a condition of perspicuity. It is on perspicuity alone that grammatical considerations have a direct bearing. But purity is not enough: therefore perspicuity, though resting on grammar, is not wholly dependent on grammatical laws. The words must be precise also; which word, as here understood, has a wider meaning than that which it often receives from critics and teachers of style. Let us understand the term as embracing everything that makes a word or phrase to represent the desired idea, to represent it exactly, to represent it completely, and to represent no other: and its meaning will then comprehend all the special rules (such as retrenchment of superfluities), to the expression of which it is sometimes restricted.—(ii.) In respect to the Number of the words or phrases, the only universal rule which can safely be propounded does in truth merely remind us, that words are but ministers of thought, that they should be used for a purpose distinctly apprehended, and that, when not so used, they are worse than useless. The number of words having been used which is sufficient to convey the meaning perspicuously, every additional word lessens perspicuity. The words required may be few, or they may be many: no rule can touch the exigences of individual cases.—(iii.) It is through failure in the Combination of words and phrases,—that is, in the construction of sentences,—oftener than through any other fault, that persons untrained in composition fall into obscurity or ambiguity. The books lay down a few excellent rules for particular cases; and some of them are still more instructive through the collection of examples. The whole doctrine may be gathered under one principle. Clear thinking must have unity of object: a complex thought, if clear, has some one element which predominates over the rest, and in due subordination to which all the others are placed. Every sentence is designed for giving expression to one leading thought: let the sentence be so framed that the pre-eminence of that thought shall unequivocally be signified. Let the expression of subsidiary thoughts be grouped about the leading assertion in such a way as to show their dependence on it; each inferior member and clause being likewise so arranged that its own unity be not lost sight of.

2. In the analysis of persuasion, we were brought so frequently on questions as to language, that the means of attaining Animation of style can hardly now be described otherwise than by borrowing from preceding illustrations.—(i.) In the Choice of words and phrases, animation is attained through two methods: it is attained directly, by the preference of the less extensive term to the more extensive; it is attained indirectly, by the preference of figurative expressions to unfigurative.—(ii.) In regard to the Number of words, the only rule must be that which was laid down as affecting perspicuity. The caution, given some time ago, may be repeated: that animation is likely to require a fullness of expression greater than that which would be appro-

priate to perspicuity.—(iii.) In the Construction of sentences, likewise, animation is governed by the same principle as perspicuity: its great law is the law of unity.

3. The gratification of taste depends primarily on the choice of objects; and this is a point beyond our province. So far, again, as the sense of Beauty is ministered to by style, three hints only can be given.—(i.) The words can have no direct power of exciting the emotion, unless as being representative of images. But this is the source which gives animation its power. Therefore the methods of producing animation are efficient also for producing elegance: and on this side no further rule can be assigned. (ii.) Words have, however, an indirect power of gratifying taste, in so far as they are examples of systematic obedience

to recognised laws; and in so far also as this obedience is evidence of skill and talent and knowledge, on the part of the writer or speaker. Therefore grammatical purity is an element of elegance in style. In this view, a value which is real, and far from being inconsiderable, belongs to the cautions which treatises on style give so often, against incorrectnesses of expression which do not go far enough to cause either obscurity or ambiguity. (iii.) Though melody of language finds its consummation and favourite seat in metrical compositions, yet prose also has, or may have, its looser and more flexible rhythm. Therefore, even in works not poetical, melody is an adjunct or element of elegance in style. (w. s.)

RHEUMATISM is a painful affection of fibrous and muscular tissues, affecting principally the larger joints, and places covered by muscles; as the wrists, elbows, knees, hip-joint, back, and loins. The internal parts also, as the heart and diaphragm, are considered capable of being affected by rheumatism. When the joints about the back and loins are affected, the complaint is called *lumbago*; when the pain is in the hip-joint, it is called *sciatica*; and *pleurodyne*, or pain in the side, when the muscles of the chest are affected. Rheumatism may occur either with fever or without it; in the first case it is termed *acute*, and in the second *chronic rheumatism*. Not long after the application of the exciting cause, the patient feels pain and stiffness in one or more joints when he attempts to move them; this quickly increases till motion becomes almost impossible, from the excessive pain attending it. Along with this local and often very general pain there occur very strong fever, much thirst, heat, and dryness of skin, strength, fulness, and hardness of pulse. The feverish symptoms are somewhat increased towards evening; and when the patient gets warm in bed the pains are more severe. In a short time some of the affected joints swell, and the pain is a little relieved, but by no means removed. As to the *causes* of this malady, it may be remarked that rheumatism is a disease of the constitution, and is induced by a poison circulating in the blood, and probably carried from one joint to another. The tendency to rheumatism is hereditary; and in some families this predisposition is very marked, and the disease is excited by the most trifling causes. Cold and damp are the most common causes of the disease, and hence the poor suffer much from it. Persons who get their clothes wet or damp, and neglect to change them, are often seized with rheumatism. Acute rheumatism is most common between the ages of fifteen and forty. It is not a dangerous disease as long as it is confined to the joints, but there is always the risk of the heart being attacked. Dr Parr remarks regarding the *diagnosis* of this disease, that "rheumatism is often so blended with gout as to prevent our seeing which is the principal complaint. In general, rheumatism occurs in consequence of an evident cause, as cold; the gout without any such cause. Rheumatism has no preceding complaints; gout is preceded by languor, flatulency, and indigestion; rheumatism is the disease of the strong and active; gout, of those advanced in life; rheumatism attacks the larger, gout the smaller joints; rheumatic limbs, though swollen, are not red like gouty. The fever of gout remits irregularly; that of rheumatism has exacerbations in the evening, and remissions in the morning. These circumstances will contribute to the distinction; but the cases so often run into each other, and differ by shades so transient and minute, that the greatest difficulty is found in the distinction of particular complaints. Rheumatic pains in the chest resemble pleurisy, and in the abdomen resemble inflammation of the bowels. In each case, the soreness to the

touch, the pain felt at the origin or insertions of the muscles, while the more appropriate symptoms of the real inflammation of the part are absent, will sufficiently mark the nature of the disease."

Acute rheumatism is to be considered as an inflammatory and febrile disease, and, as such, to be treated in the first instance by cautious blood-letting, in quantity proportioned to the violence of the disease and the strength and constitution of the patient. In all cases the bowels must be well opened. The best medicine for this purpose is a draught containing half an ounce of Epsom salts, twenty or thirty drops of antimonial wine, thirty drops of colchicum wine, and an ounce of senna infusion. After the saline purgative it is often advisable to bring out a copious sweat, and to continue that sweat over the whole body for thirty-six or forty-eight hours. The most effectual and approved method of this is to employ the compound powder of ipecacuan and opium, commonly called Dover's powder; of this we give 10 or 12 grains, having put flannels next the patient's skin, and put him in blankets. When this dose has brought out a sweat, it is to be encouraged by drinking plentifully of warm gruel or barley-water; but if it should fail to occasion perspiration, another dose must be given at an interval of four hours, and this repeated every four hours till a copious sweat breaks out over the whole body. It is proper to abstain from drinking till the sweat breaks out, as drinking too soon after taking the powder is apt to occasion vomiting. When the perspiration has continued general and copious for a sufficient time, the load of bed-clothes is to be gradually diminished; the body is to be rubbed dry with warm flannel, and great care taken for some time not to expose it to cold. When the pain and stiffness of the joints continue after the sweating, some stimulating embrocation is proper, as turpentine ointment, or volatile liniment, or camphorated oil. If the pain still continue obstinate, it may be necessary to apply a blister to any of the joints or muscular parts that require it. The essence of mustard, which has gained some reputation as an external application in rheumatism, is composed of oil of turpentine, camphor, and a portion of rosemary, to which is added a small quantity of flour of mustard.

Chronic rheumatism is distinguished by the pained parts being cold and stiff, and not easily made to perspire; by being worse in cold weather than in warm; by the patient's being very sensible to the changes of weather; and by the general health being not very greatly impaired, at least till the disease has continued many months. The affected joints remain for a long time swollen and tender, and occasionally permanently thickened and distorted. The cure of chronic rheumatism is very difficult. Many expedients have been tried, and there is a necessity for varying the treatment in almost all instances of it. Sweating and friction are proper commencements, and these must be followed up by warm bathing, warm pumping, the use of the Bath waters, or sometimes by sea-bathing, by electricity,

Rhin. and the frequent use of the flesh-brush. The system is to be invigorated by bark, wine, iron, and other tonics. The ammoniated tincture of guaiac, in the dose of two or three drachms, has been employed with success; also the oil of turpentine, from ten to thirty drops mixed with honey, or what has been a good deal employed of late, cod-liver oil, from half an ounce to an ounce. The above doses are to be taken twice a-day, and persevered in for some time. Much attention is to be paid to the wearing of proper clothing, and not to expose the body to the vicissitudes of the weather, and especially to avoid cold and damp. Much benefit is often derived from wearing Pulvermacher's electric chains.

RHIN, BAS, a department of France, bounded on the N. by Rhenish Bavaria, E. by Baden, S. by the department of Haut-Rhin, and W. by those of Vosges, Meurthe, and Moselle: length, from S.E. to N.W., 68 miles; average breadth, 30 miles; area, 1914 square miles. It has a general slope from the Vosges Mountains, extending along the west of the department, to the Rhine, which washes its eastern border in a parallel direction. In the more elevated regions there are rugged and precipitous rocks, shaggy with forests, along with deep, romantic glens: in the lower tracts broad rich plains, with vine covered hills, and some marshes near the bank of the Rhine. In the former district the prevailing geological formations are limestone, sandstone, and gypsum; the latter is composed of tertiary deposits. The whole of the department is watered by affluents of the Rhine. The largest of these is the Ill, which flows northwards, from Haut-Rhin, nearly parallel to the main river; and after receiving from the Vosges in this department the Lieporelle, Scheer, Andlau, Eger, and Bruche, falls into the Rhine a short distance below Strasburg. The Zorn, Moder, Surbach, and Lauter flow from the mountains immediately into the Rhine. Of these rivers, besides the Rhine, the Ill and the Moder are navigable. Among the mineral resources of the country are iron, coal, alum, slate, building-stone, and potters' clay. There are mineral springs at several places. The soil of the country is generally fertile, except the marshy ground along the Rhine and the barren tracts among the Vosges; and cultivation is well and extensively carried on. The winters are long and severe; in the summer, which comes on almost without any spring, sudden changes are not unfrequent; but the autumn is in general exceedingly fine. Corn, potatoes, pulse, beet-root, and hemp are the crops chiefly raised. Tobacco has been for a long time cultivated here. The vines, though reckoned inferior to those of Haut-Rhin, produce several excellent wines. There are in the department about 123,500 acres of corn land, 74,000 occupied by potatoes, 44,400 by vineyards, 158,000 by meadows, and 365,000 by forests. The meadows are favourable for the rearing of cattle, which are numerous and of a good breed. Pigs especially are bred in great quantities, and form an important article of commerce. It is estimated that there are 50,000 horses, 140,000 horned cattle, 76,000 sheep, and 90,000 pigs. Manufactures are extensively carried on: steel and cutlery, fire-arms, swords, bayonets, surgical instruments, woollen cloth, calico, leather, beer, and chemical substances, are among the articles produced. The trade is also considerable. Both the natural and the manufactured products of the country are sent to other parts of France, and to foreign lands; much of the timber being floated down the Rhine in large rafts, and sawn up in Holland. Communication is facilitated by three canals,—that between the Rhone and the Rhine, that between the Marne and the Rhine, and that of the Bruche, as well as by two railways,—from Paris to Strasburg, and from Strasburg to Basel. Bas-Rhin contains four law courts of the first instance, a tribunal of commerce, a lyceum, normal seminary, six colleges, and 1000 elementary schools. It belongs, along with Haut-Rhin, to the diocese of

Strasburg, and to the sixth military division, containing seven arrondissements. Its four arrondissements are as follows:—

	Cantons.	Communes.	Pop. (1870).
Strasburg....	12	161	242,145
Saverne	7	165	102,119
Schlestadt	8	114	139,390
Weissembourg	6	102	89,261
Total	33	542	569,855

RHIN, Haut, a department of France, bounded on the E. by Baden, S. by Switzerland and the department of Doubs, W. by those of Haute-Saone and Vosges, and N. by that of Bas-Rhin: length, 64 miles; breadth, about 36; area, 1477 square miles. Like the department already described, it lies in the valley of the Rhine, between that river and the Vosges; the southern extremity being shut in by the ramifications of Mount Jura. The summits of the Vosges are all accessible, and not entirely destitute of vegetation; many of them being of a rounded form, are called *ballons*. Upon the lower slopes there are extensive forests, penetrated here and there with meadows, containing cottages and farms. Lower down, the rich corn-fields and sloping vineyards, the numerous towns and villages that stud the country, present a beautiful scene, inclosed by the silvery border of the Rhine on the east. Next to this, the largest river in the department is the Ill, which rises in the Vosges, receives most of the other streams, and carries their waters to the Rhine. A few of the rivers in the S.W. flow into the Doubs, and thus belong to the basin of the Rhone. The mountains in some parts are formed of granitic and other primitive rocks; lower down, sandstone, limestone, and marl are found; and in the plain the tertiary formation prevails. Iron, granite, porphyry, freestone, coal, and potters' clay are among the mineral productions of the department. The soil in the centre of the plain is very good, though of inferior quality near the mountains and the river. Agriculture is much attended to. The produce of grain is generally sufficient for the demand; that of wines superabundant; the best kinds of Rhine wines raised in France are those which come from this department. The same crops are generally raised here as in Bas-Rhin. The extent of arable land is about 240,000 acres, that of vineyards 29,000, of meadows 133,000, and of forests 350,000. Horses and cattle are numerous and of good breeds; there are calculated to be in the country 25,000 horses, 100,000 horned cattle, 60,000 sheep, and 62,000 pigs. The climate is like that of Bas-Rhin, only somewhat less mild. Manufactures are actively carried on. Besides iron furnaces and forges, there are manufactories of cotton and calico,—of the latter about 500,000 pieces are annually produced; hosiery, leather, ironmongery, clocks and watches, paper, and numerous other articles are also produced. Colmar, Mulhausen, and Thann are the chief manufacturing towns. Commerce is actively carried on here; wine, oil, hemp, timber, coal, iron, and manufactured articles are exported. Communication is promoted by the navigable rivers Rhine and Ill; by the Rhine and Rhone Canal, and by the railway from Strasburg to Basel. There is an imperial court at Colmar for the departments of Haut and Bas Rhin; besides which, this department has 3 subordinate tribunals, a lyceum, 4 colleges, a normal seminary, 14 superior, and 736 elementary schools. It is divided into 3 arrondissements as follows:—

	Cantons.	Communes.	Pop. (1856).
Colmar.....	13	139	208,829
Altkirch	7	159	160,588
Belfort.....	9	191	130,025
Total.....	29	489	499,442

The inhabitants, both of this department and of that of Bas-Rhin, are of German origin; and a *patois* of that lan-

Rhin.

Rhine.

guage is generally spoken. A large proportion of the population are Protestants, especially in the lower of the two departments; and there are many Jews, who, though universally hated, have in their hands the most of the trade. These two departments, which formed the province of Alsace, once a part of Germany, came into the possession of France by the peace of Westphalia in 1648.

RHINE (anc. *Rhenus*, Germ. *Rhein*, Fr. *Rhin*, Dutch *Rijn*), one of the largest and most celebrated rivers of Europe, has its source in Switzerland and its mouth in Holland; Germany on its right bank, and France for a part of its course on the left. Politically it separates Germany from France; but if we define the country rather by the language and character of the people than by the arbitrary divisions of states, we must say that the Rhine flows through the middle of Germany, having on both sides German inhabitants, speaking the German language. The name of the river, however, was originally Celtic, *hrén*; but when the Celts were expelled by the Germans the name also gave place to one of a similar sound, *hrin*, signifying roaring. It is formed by three brooks from the N.E. slope of Mount St Gotthart, in the canton of Grisons; the mountain dividing between the Italian and German nations, and sending almost from the same point the Rhone by the lake of Geneva to the Mediterranean; the Ticino, by lake Maggiore to the Po; the Inn, by the Danube to the Euxine; and the Rhine to the German Ocean. The Fore, Middle, and Hinder Rhine are the names of the three brooks which pour down from the glaciers over rocks and cliffs in tumultuous noisy course, and unite to form the river. Of these, the last, which is the largest, flows through a most tremendous chasm, the Via Mala. For a length of 4 miles, perpendicular, sometimes overhanging, rocks rise to the height of 1600 feet on either side of the river, which rushes through the abyss, compressed in some places to a width of 10 feet. The three streams unite above Cur; and the river thus formed flows northward through Grisons, afterwards separating the county of Vaduz, belonging to the Prince of Liechtenstein, and the Vorarlberg, belonging to Austria, on the right, from the Swiss canton of St Gall on the left. It pursues this course onwards to the Lake of Constance through a narrow valley, which below Werdenberg assumes an entirely different character, and is called the Upper Rhine valley, or *Rheingau*. Instead of the bleak inhospitable rocks of the Grisons, affording only meadows and pasture land, there is here a mild climate, luxuriant vegetation, rich vineyards and corn-fields, woods, and orchards, so as to render this one of the most beautiful valleys of Germany. The chief town in the valley is Rheineck, near the head of the Lake of Constance. Among the affluents of the Rhine above this point the principal are the Plessur, Lanquart, and Ill, from the right; and from the left, the Tamina, rushing violently down from Pfeffers into the still turbulent Rhine. At Cur the river becomes navigable for boats. It enters the lake of Constance sometimes with such force that its waters meet those of the Argen and Schussach, which fall into it from the opposite side. For some distance the stream can be distinguished in the lake by its motion and its clearer water among the deep green waves around. It leaves the lake at Constance to enter another, the Lower or Lake of Zell. After its exit from the latter it flows westwards, separating the grand duchy of Baden and the canton of Schaffhausen from the cantons of Thurgau, Zurich, and Aargau, and passing Schaffhausen, where it forms the finest cataract in Europe, 300 feet broad and from 45 to 60 high. From a castle in the vicinity, the inhabitants call the fall Lauffen, or Great Lauffen, to distinguish it from another not so remarkable farther down the river. Not far below Schaffhausen the Rhine receives the Thur; and at a small village called Coblenz, the Aar, a considerable river

watering a great part of Switzerland, and augmented by the Reuss and the Limmat. As this last river has its source not far from the Rhine, above Werdenberg, and is separated from it only by an elevation of 20 feet, it has been supposed that the Rhine itself anciently followed this course, and flowed through the lakes of Wallenstadt and Zurich into the Aar. Although at the confluence the Aar is the larger of the two streams, yet as the Rhine preserves its former course, carrying along with it the waters of the other which flowed northwards, it still retains the name of Rhine. By means of this affluent the Rhine receives the waters of all the Swiss lakes it has not traversed, excepting only that of Geneva; and the number of glaciers that go to form the united stream is 270; so that before leaving Switzerland the Rhine carries away almost all the waters of that country. Below the confluence of the Aar the Rhine passes the falls of Waldshut, Lauffenburg, Seckingen, and Rheinfelden, and, flowing through Basel, enters the second part of its course. At this point it turns to the north, and leaving the narrow valleys through which it had previously flowed, enters the broad and beautiful valley of the Rhine, stretching from the Black Forest (*Schwarzwald*) on the E., to the Vosges and their continuation, the Hardt Mountains, on the W., a distance of 40 or 50 miles; and from Basel, 200 miles northwards, to Mainz. During this part of its course the Rhine separates Baden on the E. from Alsace, now the French departments, Haut and Bas Rhin, and the Rhenish palatinate, now a part of Bavaria, on the W.; and afterwards traverses the grand duchy of Hesse-Darmstadt. It passes by or near the towns of Strasburg, Carlsruhe, Spire, Mannheim, and Worms, and receives numerous affluents from the hills on either side, the largest being the Neckar, rising on the E. slope of the Black Forest, and flowing in a circuitous course through Wurtemberg and Baden, till, after passing Heidelberg, it joins the main river at Mannheim. With Mainz ends the broad, rich, vine-covered valley of the Rhine. Here, too, the Main enters the river, flowing in a zig-zag course through Franconia from the Fichtelgebirge on the E., its tawny waters not readily mingling with the bluish Rhine. This river, sweeping round from between the Donnersberg on the left, and the Odenwald on the right enters a narrow defile which extends as far as Cologne, including some of the finest romantic scenery in Europe. Between Mainz and Bingen the former northerly course of the stream is turned by the Taunus Mountains towards the west, and the southerly exposure and the shelter of the heights behind renders this part of the banks the best for the growth of the vine. The level country which the Rhine incloses in a semicircle from Worms to Bingen is known by the name of the Gau. At the latter place the Rhine, receiving the Nahe from the W., turns again in a N.W. direction, and forces its way through a long narrow cleft in the mountains. At Coblenz it receives the Moselle from the left, and a little way farther up the Lahn from Nassau on the right. At this point, too, it enters the Prussian dominions, which it had below Bingen separated from Nassau. Between Coblenz and Cologne the valley is sometimes narrow, sometimes wider, combining the beauties of both kinds which appear in the upper part of its course. Besides the places already mentioned, Bonn is the principal town here on the Rhine; and there are many old castles and ruins celebrated in the history or legends of the country. With Cologne begins the third and lowest portion of the Rhine. Here it emerges gradually from the mountains into a low plain, flowing still north-west through Prussia. It receives below Coblenz the Sieg, the Ruhr, and the Lippe from the E., and the Erft from the W., and passes the towns of Dusseldorf and Wesel before leaving Prussia and entering Holland. A short distance below this point the Rhine begins to separate into different chan-

Rhine.

Rhine. nels. Near the village of Pannerden it divides into two; the larger, which flows westwards, taking the name of Waal, and the other retaining the name of Rhine, flowing N.N.W. Further on, near Arnheim, a stream called the Yssel is sent off from the Rhine towards the N., falling into the Zuyder Zee. This channel was originally formed by a canal cut by Drusus between the Rhine and Old Yssel. A third division of the Rhine takes place at Wyck, where the smaller and more northerly branch retains the name Rhine, and flows past Utrecht and Leyden, while the other stream takes the name of Leck. A fourth and last division takes place at Utrecht into the Vecht, flowing northwards to the Zuyder Zee, and the old Rhine (*Oude Rijn*), which at one time lost itself in the sand, but has now found an outlet by a canal made in 1807. The Waal, after leaving the Rhine, unites with the Meuse or Maas, which farther down sends off a branch on the left, called the West Kil, and, flowing onwards, joins the Leck, passes Rotterdam, and enters the ocean at the promontory called the Hook of Holland. The West Kil expands into the estuary Hollands Diep, and discharges its waters by a channel on either side of the island of Over Flackee. Thus the Rhine enters the sea by six mouths, though the name is confined to one of the smallest. But it is probable that this was once the main branch, and that its character has been changed by various subsequent inundations. All the branches of the river are connected by smaller streams and artificial canals; and the whole country, from its lowness, is so liable to inundations of the river or sea that it has to be protected with embankments as far up as Wesel in Prussia. These are generally 25 or 30 feet above the lowest level of the river; but notwithstanding all precautions the country is occasionally laid under water, to the great loss of property and sometimes of lives. The whole length of the Rhine is nearly 700 miles, and it drains an area of more than 75,000 sq. miles. Its breadth at Basel is 750 feet, near Strasburg 1000, at Mainz 1500, and at Dusseldorf, the broadest part, 2300; its height at the source 7650 feet above the sea, at Constance 1335, at Basel 800, at Strasburg 453, at Mainz 274, and at Cologne 110. It is navigable for ships and steamers as far as Basel, about 570 miles from the sea; above that place it is interrupted by cataracts, and navigated only by small boats. From Basel to Strasburg it floats vessels from 25 to 30 tons burden; from thence to Mainz, 100 to 125; onwards to Cologne, from 125 to 250 tons; and below that town it is navigable for the largest ships. The waters of the Rhine are connected by canals with those of the Rhone, Danube, and Schelde. Although the free navigation of the river is secured by the peace of Vienna, exorbitant tolls and dues are exacted by every one of the states which it traverses or washes. The traffic is, however, very great, both on the river itself and on the railways that line its banks. The picturesque scenery and many historical and romantic associations connected with the Rhine make it also a place of resort for vast numbers of tourists from all countries, and have rendered this king of German rivers the theme of many a song and tradition among the people of Germany.

RHINE, Province of (Germ. *Rheinprovinz*), the most westerly province of the Prussian monarchy, bounded on the N. and N.E. by the province of Westphalia, E. by Nassau, Hesse-Darmstadt, and Rhenish Bavaria, S. by France, and W. by Belgium and Holland. It consists of five governments, whose areas and population are as follows:—

	Square Miles.	Circles.	Pop. (1855).
Cologne (<i>Cöln</i>)	1,534	11	523,680
Dusseldorf	2,084	13	1,007,570
Coblenz	2,324	12	509,164
Trèves (<i>Triër</i>)	2,779	13	506,535
Aix-la-Chapelle (<i>Aachen</i>) ..	1,601	11	436,352
Total	10,322	60	2,983,301

The southern and eastern parts of the province are mountainous, while in the N.W. there is an extent of level ground, forming the plain of the Lower Rhine. Furthest to the south is the rugged and woody Hunsrück, between the Rhine, Moselle, and Nahe. The loftiest point in these mountains, in that part called the Hochwald, has an elevation of 2526 feet. North of these are some branches of the Sauerland Mountains, which extend northwards on the right bank of the Rhine as far as the Ruhr. Part of the Westerwald also lies in this province; the most remarkable portion being the Siebengebirge, a basaltic group near the Rhine above Bonn. Another chain of hills here is the Eifel, a continuation of the Ardennes, extending between the Aho and Moselle, as far as Coblenz. Forests cover the loftier summits of the mountains, and vineyards their lower slopes; the plains are occupied with rich pastures and corn-fields. The chief river is the Rhine, which for 180 miles traverses the province, and receives most of the other rivers that water it. Among its affluents the Moselle is the largest, flowing from France through a deep narrow valley into the left bank of the Rhine. From the same side flow the Nahe and Erft; while the Sieg, Ruhr, and Lippe, which flow in the opposite direction, traverse the province for a part of their course. Agriculture is actively carried on here. The extent of arable land in 1852 was 2,732,558 acres; of gardens and vineyards, 154,903 acres; of meadows and pasture land, 1,256,836 acres; of wood, 2,031,773 acres; and of waste land, 605,252 acres. Live stock are reared in considerable numbers; and the province contained in 1855, 122,511 horses, 839,789 horned cattle, 492,364 sheep, 127,031 goats, and 242,283 pigs. For mineral wealth, this is the most important province of Prussia; more than 35 per cent. of the total value of mineral produce, or upwards of L.4,000,000, being derived from it alone. Silver, iron, copper, lead, marble, porphyry, freestone, basalt, coal, sulphur, alum, &c., are the productions of the country. In manufacturing industry, the province of the Rhine occupies the first rank, not only in the Prussian possessions, but in the whole of Germany. Cotton, woollen, and silken stuffs; lace, paper, hardware, machinery of all kinds, musical instruments, beer, brandy, chemical substances, sugar, and tobacco, are among the articles produced. Trade is also in a flourishing condition here, and is favoured by the Rhine steamers, and by the railways which connect the principal towns with one another, and with the centres of commerce in the adjacent countries. The country now occupied by the province belonged, after the fall of the Roman empire, to the Frankish monarchy, afterwards to that of Lorraine, and finally to Germany. The various officers appointed by Charlemagne, under the title of *Gaugrafen*, gradually became independent of the imperial power, and rose to be permanent and hereditary possessors of the land; so that in the eleventh century the country was divided among many independent states, including some of the possessions of the courts palatine, and of the archbishops of Mainz, Trèves, and Cologne,—the three spiritual electors of the empire. Prussia had previously to the present century only the principality of Mörs and the duchies of Cleve and Yeldern. At the time of the peace of Luneville in 1801, there were here 100 separate states of the empire; the Rhine was then made the frontier of France; and the Prussian possessions fell to that country. In 1814, not only these lands were restored to Prussia, but the whole of the other states were united in a mass, and added to that kingdom, of which they formed at first the two provinces of Jülich-Cleve-Berg and Lower Rhine, but were subsequently united into one.

RHINOCEROS. See MAMMALIA.

RHIO, or RIOW, a Dutch seaport in the East Indies, on the small island of Bintang, off the south extremity of the Malay peninsula, 50 miles S.E. of Singapore. It is a

Rhode
Island.

neat place, regularly laid out, consisting of a European and a Chinese town; the former clean and handsome, the latter somewhat dirty. It has a fort, governor's house, church, and school. The harbour is large and safe, though the entrance is difficult and dangerous. Rhio is a thriving town, and has a very considerable trade. Pop. 6000.

RHODE ISLAND, the smallest of the United States of North America, lying between N. Lat. 41. 18. and 42. 3. W. Long. 71. 6. and 71. 55.; bounded on the N. and E. by Massachusetts, S. by the Atlantic, and W. by Connecticut. Its length from N. to S. is 47 miles; greatest breadth, 37; area, 1306 square miles. The surface, though undulating and broken, rises in no place to the elevation of mountains, hardly even to what may be called hills; the highest point, Mount Hope, in the E. of the state, being only 300 feet above the sea. Narraganset Bay, a fine sheet of water, stretches northwards from the Atlantic, and divides the state into two unequal portions. Its length is about 30 miles, and its breadth about 12. It has various arms stretching into the land, especially on the eastern side. Among these are Mount Hope Bay, stretching to the N. E.; Providence Bay, to the N.; and Greenwich Bay, to the N. W. The greater part of the state lies to the W. of this inlet, a small portion to the E., and some part is composed of the islands in the bay. Rhode Island, which has given its name to the state, has a length of 15 miles, an average breadth of 3, and an area of about 50 square miles. The fertility of its soil, and mildness and salubrity of its climate, have made this a favourite place of resort, and obtained for it the appellation of the Eden of America. To the W. of it lies the island of Canonicut, to the N. W. Prudence Island; while Block Island, in the Atlantic, about 10 miles off the coast, also belongs to this state. The rivers that water the state are of no great length or volume, but flow with a considerable fall and a steady supply of water, so as to afford good water-power. Providence River, flowing southwards from Massachusetts into the north arm of Narraganset Bay, with its affluents the Pawtucket and Pawtuxet, and the Pawcatuck, which waters the S. W. of the state, and falls into Stonington harbour in Connecticut, are the principal streams that flow through Rhode Island state. The mineral resources of the country are not of much importance. Iron, anthracite coal, limestone, marble, and serpentine have been obtained here; but no mines, and only a few quarries, are worked. The continental part of the state has a soil composed of gravelly loam, which is pretty fertile, though somewhat difficult of cultivation. On the islands, where the formation is in general slaty, the soil is more productive. Throughout the state the soil is more suitable for grazing and dairy farming than for the plough. Rhode Island itself is celebrated for its cattle and sheep, butter and cheese. The whole extent of cultivated land in the state amounted in 1850 to 356,487 acres, and the produce was 539,201 bushels of maize, 215,232 of oats, 651,029 of potatoes, 5036 of grass seeds, 129,692 lb. of wool, 995,670 lb. of butter, 316,508 lb. of cheese, and 74,818 tons of hay; besides more or less of rye, barley, wheat, pulse, hops, &c. The value of orchard fruits amounted to L.13,328, that of market products to L.20,475, that of live stock to L.319,293; and that of slaughtered animals to L.139,056. Oak, chestnut, walnut, and pine trees are the chief kinds of timber grown in the state; but there are no extensive forests. The climate is mild and temperate, not unlike that of Great Britain, the vicinity of the ocean tending to moderate the heat of the summer and the severity of the winter. Manufacturing industry is extensively developed in Rhode Island, and is assisted by the great amount of water-power in the country. It contained in 1850, 1144 establishments, each producing goods upwards of L.100 in value. Among these were 158 cotton factories, with an aggregate capital of L.1,335,000, employing 4959

Rhode
Island.

men and 5916 women, consuming L.755,950 worth of raw materials, and producing goods to the value of L.1,343,147; 45 woollen factories, with a capital of L.202,600, employing 987 men and 771 women, consuming L.292,780 worth of raw materials, and producing goods valued at L.496,209; 21 forges, furnaces, &c., with a capital of L.127,200, employing 1020 men, consuming L.77,085 worth of raw materials, and producing 11,208 tons of cast and wrought iron, valued at L.198,144; several breweries and distilleries; and 10 tanneries, with a capital of L.8580, consuming L.8460 worth of raw material, and producing manufactured leather to the value of L.15,632. In the manufacture of cotton this state is, in proportion to its population, the first, and in that of woollen stuffs the second among the states of the Union. Ship-building is not so much attended to now as it once was, owing to the failure of the necessary supply of timber. An active commerce is carried on, both with foreign countries and with the seaports of the United States. Cotton and woollen stuffs, along with apples, cheese, and butter, form the principal articles exported. The value of the imports in 1852 was L.42,017, and that of the exports L.37,325. The number of vessels built in the year was 14, tonnage 3205; the total tonnage of those owned in the state 41,049, of those that entered 20,350, and of those that cleared 16,929. Many of the ships are employed in the whale, cod, and mackerel fishery. Internal communication is provided for by railways, of which there were in January 1857, 65 miles in operation, connecting Providence the capital, with the chief towns in the adjacent states. There are in Rhode Island 93 banks, 38 of which are in Providence, besides 18 savings-banks, containing in May 1855 deposits to the amount of more than a million sterling. The executive power is vested in a governor, elected annually by the people, along with a lieutenant-governor, secretary of state, treasurer, and auditor, appointed in the same way. The salary of the governor is L.200. Legislative power is in the hands of a general assembly, consisting of a senate, composed of the governor, lieutenant-governor, and a member from each of the 32 towns in the state, and a house of representatives of 72 members. The right of voting, and of being elected to public office or membership of the legislature, is granted to every citizen of the United States owning real estate to the value of L.27, or L.1, 8s. a year. The judicial establishments consist of a supreme court and a court of common pleas; the former consists of one chief and three associate justices; the latter is held by one member of the supreme court in each county of the state. There is a state prison and a jail at Providence. Considerable attention is paid by the government to education. There is a university at Providence, which is in a flourishing condition. Besides this, there were, in 1850, 46 academies, with 75 teachers and 1601 scholars; and 416 primary public schools, with 518 teachers and 23,130 scholars. A normal school and a reformatory school are supported by the state; and there is a permanent school fund of L.15,391. There were in the state, according to the census of 1850, in all 221 places of worship, with 98,736 sittings; of the former, 100 belonged to Baptists, 26 to Episcopalians, 23 to Methodists, 21 to Congregationalists, 18 to Quakers, 7 each to Roman Catholics and Christians, 4 each to the Union Church, Unitarians, and Universalists, 2 each Swedenborgians and the Free Church, and 1 each to Jews, Mariners, and Second Adventists. The total amount of taxable property in Rhode Island in 1855 was L.23,161,490. The country was originally occupied by the Narraganset Indians, and was first colonized by Europeans in 1636. Roger Williams, expelled from Massachusetts on account of his religious and political opinions, descended the Pawtucket, and settled on a piece of land which he bought from the Indians, and called Providence, in acknowledgment of "God's merciful providence to him in his dis-

Rhodes. tress." He was soon joined by a number of settlers; and he not only was among the first who allowed perfect liberty of conscience to men of all religions, but did much to enlighten and elevate the natives, whom he restrained by his mild influence from many acts of violence against his former persecutors. Two years afterwards another settlement was formed at Newport, by William Coddington and seventeen others, who had also been expelled from Massachusetts. Other settlements were subsequently formed; and these were united under the title of Rhode Island and Providence Plantations, and received a charter from Charles II. in 1663. This being one of the most liberal granted in America remained in force for 180 years. For a long time after the settlement of the colony, the prosperity and happiness of its people is attested by the barrenness of its annals in events. But in the revolutionary war the state played a conspicuous part. From the beginning of the contest Rhode Island was resolutely opposed to the British claims, and sent delegates to the first Congress in 1765. In 1776 a strong British force, under Clinton and Parker, sailed from New York, and occupied Rhode Island, blockading in the harbour of Providence the squadron of Commodore Hopkins. The Americans laid siege to Newport in 1778, but without success; and during their retreat an indecisive action took place at Quaker Hill. In 1779 Newport was abandoned by the British; and in the following year a French force arrived here, and the country was not further molested by the British. Rhode Island was the last of the original states to agree to the constitution, and only did so in 1790. To the war with Britain in 1812 the majority in this state was opposed; and like the neighbouring states it gave no support to the arms of the Union. In 1840 an association was formed for the purpose of amending the state constitution, and they called a convention for this purpose. A new constitution was framed, and supported by a party in the state; but owing to the illegality with which it had been prepared, was not recognised by the government, who proceeded, by another convention, to draw up a second constitution. The general excitement that prevailed, and the attempts of the suffrage party, as they were called who supported the illegal constitution, to obtain the government, prevented the other scheme from coming into operation; but their designs were finally frustrated, and a third constitution framed, which was agreed to nearly unanimously in 1844. Rhode Island is divided into five counties as follows:—

	Pop (1850).	Capitals.
Bristol	8,514	Bristol.
Kent	15,068	E. Greenwich.
Newport.....	20,007	Newport.
Providence	87,525	Providence.
Washington	16,430	Kingston.
Total.....	147,544	

RHODES, an island in the Ægean Sea, belonging to the Turkish empire, lying off the S.W. coast of Asia Minor, between N. Lat. 35. 52. and 36. 28, E. Long. 27. 40. and 28. 15.; about 10 miles S. of Cape Alepo. Its length is about 45 miles from N.E. to S.W., its greatest breadth 18 miles, and its area nearly 424 square miles.

Aspect of
the coun-
try.

The island is diversified in its surface, and contains in its centre an elevated mountain named Artemira (anciently *Atabyris*) which commands a view of the whole island. From this height there is a most extensive prospect of the island around its base; of the elevated coast of Asia Minor on the N.; on the N.W. the Archipelago, studded with its numerous islands; on the S.W. is seen Mount Ida in Crete, veiled in clouds; and on the S. and S.E. the vast expanse of waters which wash the African shore. Here and there on the island are seen ranges of moderately elevated hills, on which are found numbers of ancient pines, planted by the hand of nature. These forests were formerly very

thick, but they are now greatly thinned by the Turks, who cut them down, and take no care to plant others in their place. On the farther side of the nearest range of hills the surface of the island falls lower, and several hills in the form of amphitheatres extend their bases as far as the sea.

Rhodes was famed in ancient times for its delightful climate, and it still maintains its former reputation. The air is pure and salubrious, and there is hardly a day throughout the year in which the sun is not visible. The winds are liable to little variation; they blow from the west often with great violence for nine months in the year, and at other times from the north; and they moderate the summer heats, which are chiefly felt during the months of July and August, when the hot winds blow from the coast of Anatolia.

Rhodes, in addition to its fine climate, is blessed with a fertile soil, and produces a variety of the finest fruits and vegetables. Numerous streams and rivulets, which take their rise from the summit of Mount Artemira, water the surrounding plains and valleys of the island. The inhabitants have a great taste for gardens; and around the villages are several cultivated fields and orchards, containing fig, pomegranate, and orange trees. On the sloping hills carob-trees, and others both useful and agreeable, still grow abundantly; the vine also holds its place, and produces a species of wine which was highly valued by the ancients, though it seems to have degenerated greatly in modern times. The valleys afford rich pastures, and the plains produce every species of grain: the wheat is of an excellent quality; and, but for the extortions of its barbarian rulers, the island might be the seat of agriculture as well as commerce, and might export large quantities of corn.

The commerce of the island has been, since 1846, increasing at a rapid rate. Many British manufactures are imported by indirect routes, through Smyrna, Constantinople, Beyrout, and other places. Cotton stuffs, calicoes, and gray linen are among the goods most in demand. It is not so much, however, the peasantry of the island who use these British goods, for they prefer their own home-made stuffs; but they are exported to the neighbouring coast of Anatolia, between Boudroum and Adalia, and thence conveyed into the interior. The following table exhibits the shipping and trade of Rhodes from 1851 to 1855:—

Year.	Number of Vessels	Tonnage.	Crews.	Value of Imports	Value of Exports.
1851	2031	100,027	9,139	L.39,561	L.15,477
1852	2116	112,847	15,101	140,721	30,770
1853 ..	2287	114,222	15,985	143,577	52,357
1854	2156	115,882	15,615	187,515	109,923
1855 ...	2303	134,502	18,065	181,704	108,884

The expansion of the trade has been very much owing to the establishment of steam navigation direct to the island. As yet there are no British steamers that call here; but there are many which ply regularly on this line under the French, Austrian, and Turkish flags.

The only town of any importance in the island is the capital, Rhodes, which stands at the north-east extremity. It rises in an imposing manner from the sea, on a gentle slope in the form of an amphitheatre. It is surrounded with walls and towers, and defended by a large moated castle of great strength. These fortifications are all the work of the Knights of St John. Above them rise the domes and minarets of the mosques, and the tufted stems of the palm-trees, which adorn this like most other oriental towns. The interior of the city does not correspond to its outward appearance. Those ancient streets which were laid out with such art and on so great a scale, and that

Rhodes.

uniform series of buildings which were monuments of taste, have been succeeded by narrow winding streets, and buildings without grace, ornament, or regularity. There are still some monuments which testify that the island was once possessed by the Knights of Rhodes, namely, their arms, which still adorn the fronts of several buildings, and their tombstones in the church of St John; the walls and towers also bear marks of their heroic resistance to the Ottoman arms. But there is no longer any monument of its grandeur in times of antiquity; there is no theatre, no magnificent temple or spacious portico. The statues and paintings for which Rhodes was famed in the early ages of Greece and Rome have all been removed. Not a vestige is to be seen of the Colossus, described as 70 cubits high, and reckoned one of the wonders of the world. The streets bear everywhere marks of desolation. One half of the houses in the city are in ruins, and one half in the suburbs are uninhabited, though those occupied by the Greek inhabitants are generally good stone buildings, surrounded with gardens well stocked with all the fruits of the climate. The principal buildings which remain are the church of St John, which is become the principal mosque; the hospital, whence the charity of the knights was liberally dispensed to the faithful from all quarters of the world, and which has been transformed into public granaries; the palace of the grand-master, now the residence of the pasha; and the senate-house, which still contains some marbles and ancient columns. Of the streets, the best and widest is a long street which is still called the Street of the Knights. It is perfectly straight, and formed of old houses, on which remain the armorial bearings of the members of the order. On some of these buildings are still seen the arms of the Popes and of some of the royal and noble houses of Europe.

Rhodes has at present two harbours. The least of these lies towards the east, and its entrance is obstructed by a barrier of rocks, so as to admit the entrance of but one ship at a time. It is sufficiently sheltered, but by the negligence of the Turks the sand has been suffered to accumulate until it has been gradually almost choked up. The other harbour is larger, and also in a bad condition; here frigates of thirty guns may anchor, and are sheltered from the west winds, though they are exposed to the north and north-east winds. The two harbours are separated by a mole which runs obliquely into the sea. At the eastern entrance is the fort of St Elmo, with a light-house; but the light is very feeble, and visible only a few miles. The town contains a Turkish library and three Mohammedan colleges. Manufactures of red leather and shoes are carried on here. Pop. about 15,000. The sites of Lindus, Jalyus, and Camirus, which in ancient times were the chief towns in the island, are now marked by insignificant villages, with a few remains of antiquity.

History.

In the very earliest times the beauty and fertility of the island seem to have brought it into notice: it is said to have had several names; and the one that it has since retained signifies probably the Island of Roses, from *ῥόδον*, a *rose*, which was its symbol. After various poetical legends about its original inhabitants, we learn that it was colonized by the Dorians, who emigrated from their native land; and that its cities, Lindus, Jalyus, and Camirus, formed, along with Cos, Cnidus, and Halicarnassus, the Dorian Confederacy, or Hexapolis, worshipping at the common sanctuary of Apollo on the Triopian headland. The island was then divided among the three confederate towns, and soon attained a flourishing condition, sending out colonies to the coasts of Lycia, Cilicia, Sicily, Italy, Spain, and the Balearic Islands. It was not till a later period, however, that Rhodes became one of the great maritime and political powers in Greece. After the Persian wars it belonged to the Athenian confederacy, and remained in subjection to it for the

most part of the Peloponnesian war. But in 412 the aristocratic party gained the ascendant, and the Rhodians deserted the Athenian cause. In 408 the new capital, Rhodes, was built and peopled by the other three cities. The architect was Hippodamus of Miletus, who had planned and embellished the Piræus at Athens; and the new city soon became one of the most splendid in the world, adorned with magnificent buildings and exquisite works of art. When Conon and his fleet restored the Athenian power by his victory off Cnidus, Rhodes again embraced the victorious cause; but her fidelity during the subsequent contests was not very great. Sparta afterwards received the allegiance of the island; and in the Social War (B.C. 157-5) it joined the alliance against Athens; and, with the assistance of the Carian monarch Mausolus, succeeded in achieving independence. But finding the power of that king dangerous to their liberties, the Rhodians once more sued for the Athenian protection, which they obtained through the eloquence of Demosthenes. But neither they nor the rest of Greece could resist the overwhelming power of Macedonia, though Memnon, a Rhodian, was one of the ablest generals under the last Persian king, and attempted to check the career of Alexander. Rhodes received a Macedonian garrison; but it was expelled after the death of Alexander, and a resolute resistance was begun to the Macedonian power. This formed one of the most illustrious periods in the history of the island. The capital was besieged in 303 B.C. by Demetrius Poliorcetes, with a large army and a complete train of the artillery of that age. Although a breach was effected in the walls, the desperate valour of the defenders foiled all the attempts to carry it by assault, and cost the besiegers the lives of some of their generals and a great number of their soldiers. This heroic resistance obtained for the Rhodians great renown; they enjoyed the friendship of Rome, and obtained possession of some of the adjacent islands and coasts. For arts as well as arms the island was then renowned: Æschines, who had contended in eloquence with the greatest of orators, opened a school of rhetoric here; Protogenes embellished the city with his paintings; and Chares of Lindus with the celebrated statue, in which

Rhodes.

“the gigantic king of day
On his own Rhodes looks down;”

and the Rhodian laws, especially on maritime affairs, were reckoned the best in antiquity, and many of them adopted into the Roman code. The Colossus, not probably striding over the harbour, stood for fifty-six years, till an earthquake prostrated it in 224 B.C. Being the sovereigns of the seas, the Rhodians by their fleets rendered good service to Rome, with whom they were in alliance, and retained their independence for a long time. The severest blow they suffered was from Cassius in 42 B.C., who plundered it even to the bare temple walls in the desperate cause of liberty, for the island had embraced the side of Cæsar. Under the empire the liberty of Rhodes was permitted and withdrawn according to the caprice of the sovereign. It continued a part of the Roman empire; after its partition, of the Eastern, till 616 A.D., when Chosroes the Persian obtained possession of it for a short time. It was subsequently conquered by Moawiyah, one of Othman's generals; but, recovered by the Byzantine empire, it proved the last of their Asiatic possessions that succumbed to the infidel. In 1308 it was granted by the Emperor Emmanuel to the Knights of St John, who soon after resisted a siege by the Sultan Othman. They strengthened the natural advantages of the place by skilful fortifications; and by discipline and equipments made themselves nearly a match for the superior numbers of the Turks. Nor did the knights restrict their efforts to self-defence; they conquered Smyrna, and established an outpost there in 1344; and at a later period formed a league against the common enemy of Christendom.

Rhodo-
mann
||
Rhône.

But in 1401 Smyrna was taken by Timour: in 1480 Mahomet II. besieged Rhodes with a vast train of artillery; and, though then averted by the courage of its few defenders, the downfall of the place could not long be averted. The last and most famous siege of Rhodes took place in 1522, when, after a desperate resistance for four months to the overwhelming numbers of the Ottomans, the knights, being left unassisted by all the European powers, capitulated on honourable terms, and evacuated the island. On the first day of 1523, Villiers de Lisle Adam, the grand-master, embarked, the last of the small band, carrying away all the property of the order, and leaving the ruins of their city to the enemy. The knights subsequently settled in Malta, where they also gained great renown. Rhodes has since been in the possession of the Turks, and is now the residence of the pasha of the Archipelago. Pop. 20,000, chiefly Greeks, but including 5000 Turks and about 1000 Jews.

RHODOMANN, LAURENTIUS, a German scholar, was born at Sarswerfen in 1546, and was educated at the expense of the Count of Stolberg. The great effort of his life was to revive Greek learning. He studied it closely at the university of Rostock. He then taught it with enthusiasm at Jena. His zeal in the same cause did not cease after his translation in 1601 to the chair of history at Wittenberg. He continued to write Greek verses, and to edit and translate Greek works till shortly before his death in 1606. Among the most important publications by Rhodomann are the following editions of Greek authors:—*Anonymi Poetæ Græci*, 8vo, Leipsic, 1588; *Quintus Calaber*, Hanover, 1604; and *Diodorus Siculus*, in 2 vols., Hanover, 1604.

RHOMBROID, and RHOMBUS. See GEOMETRY; *Definitions*.

RHONE (anc. *Rhodanus*), a river of Europe, belonging principally to France, rises in Switzerland at the Furka Pass, near Mount St Gotthardt, whence also flows the Rhine in an opposite direction. It dashes down in a series of cascades, and flows south-west through the canton of Valais, receiving numerous affluents from the Bernese Alps on the right, and the Pennine on the left. At Martigny the river takes an abrupt turn to the north-west, and flows through a flat, swampy, and very unhealthy valley into the Lake of Geneva, which stretches in the form of a half-moon between the steep rocks and cliffs of Savoy on the south, and the sloping vineyards of the Pays de Vaud on the north. The pure, blue waters of the swiftly-flowing river issue from the lake at Geneva; but they do not long retain their clear colour, as they mingle with the muddy Arve descending from Mont Blanc. After traversing the canton of Geneva in a S.W. direction, the Rhone leaves Switzerland, and flows southwards along the frontier between France and Savoy, through a narrow pass between the Alps and Mount Jura. A road traverses the defile midway up the declivity, and this entrance to France is commanded by the Fort de l'Écluse, a strong fortress, with batteries hewn out of the solid rock. A short distance below this fort is the Perte du Rhone, where the river plunges into a deep chasm, covered over with massive fragments of rock that have descended upon it. Many of these have been removed by the Sardinian government, so that the cascade is not so remarkable as it once was. At this place the Rhone receives from the right the Valserine, a picturesque stream flowing down from Mount Jura. The southerly course of the river continues as far as St Genis, near which it receives from the south the Guiers, a small stream which separates Italy from France. At this point the Rhone turns abruptly to the N.W., separating the French departments of Ain and Isère, which it continues to divide, flowing afterwards more towards the west, until it reaches Lyons; receiving during its course the Ain

from the north, and emerging a short distance above Lyons from the hilly region it had been previously in. At Lyons the sluggish, gently-flowing Saône from the east joins the Rhone, its muddy water being distinguishable for some distance from the clearer river that it joins. The united stream has a considerable breadth, and flows nearly due south, through a beautiful country studded with villages, among rows of poplar and willow trees. It separates the departments of Rhone, Loire, Ardèche, and Gard on the right, from those of Isère, Drôme, Vaucluse, and Bouches-du-Rhone on the left, and falls into the Mediterranean by two mouths in the last of these departments. The chief affluents of the Rhone from the right, flowing from the Cevennes, are the Doux, Ardèche, Cèze, and Gardon, and they are generally of small size; while on the left the river receives from the Alps the larger tributaries Isère, Drôme, Vigne, and Durance. The chief towns along this part of the Rhone are the ancient Vienne, Valence, Montélimart, Orange (which gave a title to the illustrious house of Nassau), and Avignon, once the place of exile of the Popes. At Arles the river divides into the little Rhone, flowing S.W., and the main stream pursuing a S.E. course. Neither of these channels is of much use for navigation, as their mouths are obstructed by bars; but vessels may enter by two canals, that of Martigues from the E., and that of Beaucaire from the W. From Lyons to the sea the Rhone is regularly navigated by steamers, though the rapidity of the current and the shifting sands in the bed of the river render the progress upwards difficult. Above Lyons steamers ply, but not so regularly, on the Rhone as far as Seyssel, on the Swiss frontier, and on the Saone as far as Chalons. The whole length of the Rhone is about 530 miles, of which 350 are in France: the height of its source is 5904 feet above the sea, that of the Lake of Geneva 1142 feet. The area watered by the Rhone and its affluents is estimated at 11,300 square miles.

RHONE, a department of France, next to that of Seine the smallest in the kingdom, bounded on the N. by the department of Saône-et-Loire, E. by those of Ain and Isère, S. and W. by that of Loire: length, from N. to S., 60 miles; greatest breadth, 28; area, 1042 square miles. The western part of the department is occupied by a prolongation northwards of the Cevennes, known by the names of the Lyonnais, Beaujolais, and Charolais heights. This range here forms the watershed between the Mediterranean and the Atlantic; for the rivers that descend its eastern slope flow southwards by the Saône and Rhone into the Mediterranean, and those that run down the opposite side swell the volume of water which the Loire pours into the Atlantic. One of the highest summits of this chain, near the middle of the west side of the department, is Tarare, which rises to the height of 4500 feet. The greater part of the chain has a bare, steep, and rugged character, though the mountains of Charolais to the north have more gentle slopes, and are generally well wooded. From the neighbourhood of Beaujeu, in the north of the department, two branches diverge from the principal range,—one towards the N.E., and the other to the S.E., between the valleys of the Azergue and Saône. From the southern part of the chain, another offset, the Mont d'Or, stretches N.E., and divides the Brevanne from the Saône and Rhone. The mountains are for the most part composed of granitic and other primitive rocks; the country further down belongs to the secondary, and that along the rivers to the tertiary formation. Coal and copper are the most valuable minerals of the country; both are worked to some extent. Porphyry, marble, sandstone, gypsum, and potters' clay are also found here. The department is almost entirely watered by the affluents of the Saône and Rhone, which was its eastern border, a very

Rhone.

Rhubarb. small part only lying to the west of the hills. The soil is for the most part not fertile; and so, notwithstanding the excellent cultivation, the produce of grain is not sufficient for home consumption. Potatoes, however, are more extensively produced. The most important of the natural productions of Rhone are its wines, many of which are highly esteemed. The climate is healthy, but from the mountainous nature of the country somewhat colder than other regions in the same latitude. The extent of arable land is estimated at 353,000 acres, of meadows 90,000, and of vineyards 75,000. The forests are of small extent, and afford comparatively little wood. Besides the crops already mentioned, pulse, madder, millet, hemp, and flax are raised. The quantity of wine produced annually is about 17,000,000 gallons. Large numbers of cattle are reared; also goats in the hilly regions, and many silk-worms. Rhone contains about 10,000 horses, 71,000 horned cattle, 66,000 sheep, 18,000 goats, and 14,000 pigs. The annual value of the coal worked is about L.8000, of the copper L.10,000, and that of the produce of all the quarries L.20,000. It is for manufactures, however, that the department is chiefly distinguished. Lyons is for silk fabrics the most celebrated city in Europe; satins, velvets, lace, shawls, ribands, hosiery, &c., are also made in great quantities. Muslin, hats, paper, glass, hardware, machinery, and other articles are among the manufactures of the country. There is an active trade in raw and manufactured articles, as well as in wines, coal, timber, &c. Communication is facilitated by the two navigable rivers, by the canal of Givors in the south of the department, and by the railways from Chalons to Lyons, and from Lyons to St Etienne. The department forms the diocese of Lyons, and contains a court of appeal at Lyons and two inferior tribunals, an academy of theology, science, and literature, a secondary school of medicine, a lyceum, normal seminary, college, 10 superior and 663 elementary schools. Its divisions are as follows:—

	Cantons.	Communes.	Pop. (1856).
Lyons.....	17	129	460,034
Villefranche	9	130	165,957
Total	26	259	625,971

The capital is Lyons.

RHUBARB is the root of various species of *Rheum*, Nat. Ord. *Polygonacea*. The rhubarb of commerce is obtained through various sources, and appears to have been known to the ancients, although much obscurity invests the history of the *Rha* or *Rheon* of the ancient Greek writers, and the *rhacoma* of the Romans. These names are supposed to have been applied to the dried roots of *Rheum rhaponticum* of Linnæus, which is a native of Thracia, and of the coasts of the Euxine and Caspian seas, and part of Siberia. The rhubarb root was first introduced into European pharmacy by the Arabians, and was highly valued by Avicenna. The finer kinds of rhubarb are received from Chinese Tartary and possibly from Thibet. It finds its way to Europe through Russia; and from the fact, that the best kind was formerly sold by the merchants of Anadoli or Anatolia, it was called *Turkey* rhubarb. This sort is now generally imported from Russia and Turkey. There is another sort, rather inferior, which is called *Canton* or *East Indian* rhubarb, imported from Canton or Singapore. Of late, much rhubarb root has been prepared in Europe, and is either used as a milder medicine or for the purpose of sophisticating the finer foreign sorts. The town of Banbury in Oxfordshire has long been famous for the cultivation and preparation of English rhubarb, which is the product of *Rheum rhaponticum*; no other species is found to be of any value medically. Within the last few years the petioles or leaf-stalks of the various species of rhubarb have become a most

important staple of our vegetable markets, in consequence of their agreeable subacidity and their succulence, which renders them very useful and wholesome in tarts and other forms of food. The chief species of rhubarb now known are:—*Rheum palmatum* (Linn.), supposed to yield the Turkey rhubarb root; it is also cultivated in this country as a culinary vegetable. *R. undulatum* (Linn.) is the source of the French rhubarb. *R. compactum* (Linn.) is also cultivated in France for its root, which is prepared to imitate the foreign drug. *R. Emodi* (Wallich) yields that kind of East Indian rhubarb known in trade as Himalayan; it is also a favourite garden species. *R. rhaponticum* (Linn.) is the commonest kind in cultivation in our gardens. Hundreds of tons of the leaf-stalks of this species are sent to our markets every week during the season, and form a cheap and refreshing food for all classes. The roots also are prepared as before stated. Ten or twelve other species are known, and some of them are probably as well adapted for the purposes of medicine or cookery as those above mentioned, but they have not been so well examined.

The quantity of rhubarb root imported in 1858 was 211,117 lb., the estimated value of which was L.39,300. This large quantity is entirely consumed in pharmacy, it being applied to no other use than as a mild aperient medicine. (T. C. A.)

RHUDDLAN, or **RHYDDLAN**, a parliamentary borough of N. Wales, county of Flint, on the Clwyd, which is here crossed by two bridges, 3 miles N.N.W. of St Asaph. It was once a large and important place, but is now distinguished for little except its ancient remains; it contains only a few streets, but is generally well built, and has several places of worship belonging to Wesleyan and Calvinistic Methodists, Baptists, and Independents. The castle of Rhuddlan is a square red stone edifice, with six massive round towers, and has little pretensions to architectural elegance. Its age is not certainly known, but it was in existence in the eleventh century, and was attacked and burned by King Harold in 1063. In after-times it was a place of much importance and the scene of many historical events. Of the house where Edward I. held in 1283 the Parliament which secured the Welsh rights a portion still remains, and is marked by an appropriate inscription. It was in Rhuddlan that the infant son of Edward I. was acknowledged Prince of Wales. In the civil war the castle was held by the royalists, but was taken by General Mytton in 1646, and soon after dismantled. The River Clwyd is navigable as far as Rhuddlan for vessels of 60 tons. Pop. (1851) of the borough, 1472; of the parish, 3049.

RHUMB, and **RHUMBLINE**. See **NAVIGATION**.

RHYME (Sax. *rim*; Germ. *reim*), in poetry, is the consonance of sounds in the last syllable or syllables of verses. In the former case it is called *male* rhyme, in the latter *female*. Some derive it from the Greek *ῥυθμος*, which is a palpable error. Rhyme, as an accompaniment of verse, cannot be traced farther back than to the *rymours* of Normandy, the *troubadours* of Provence, and the *minnesingers* of Germany. (See **POETRY**.)

RHYTHM, (Gr. *ῥυθμος*, *measure*) is the metrical arrangement of speech. (See **RHETORIC**.)

RHYTHMOMETER, from *ῥυθμός*, and *μέτρον*, an instrument contrived to measure equal portions of sounds in musical performance, and to mark the time, at longer or shorter intervals, according to adjustment of the mechanism. Maelzel's *metronome* is the instrument of this kind most generally in use, although one more simple and less costly might easily be made. Diderot, in the fourth memoir of his mathematical works, suggested a musical chronometer, but added, "Le seul bon chronomètre que l'on puisse avoir, c'est un habile musicien qui ait du goût, qui ait bien lui la musique qu'il doit faire exécuter, et qui sache en battre la mesure." The chief utility of a rhyth-

Ruddlan
||
Rhythmo-
meter.

Riazan. mometer consists in the power of fixing the duration of time which a composer wishes to give to the equalized portions of his composition, as indicated by the vibrations of a pendulum, and as marked by relative numerals affixed to characters of musical notation. Almost all pieces of music of classical importance are now printed with indications of the metronome measures of time; and this is a great improvement, inasmuch as before the present century we had nothing but tradition, and often no tradition at all, to guide us in the comparative slowness or quickness with which the notes of a musical composition were to be performed. (G. F. G.)

RIAZAN, or **RJAZAN**, a government of European Russia, bounded on the N. by that of Vladimir, E. and S. by that of Tambov, and W. by those of Tula and Moscow, lying between N. Lat. 53. and 55. 40., E. Long. 38. 18. and 41. 30: length, from N. to S., 180 miles; greatest breadth, 125; area, 16,454 square miles. It is in no part mountainous, but the surface is diversified by low hills, undulating champaigns, rivers flowing between elevated banks, small forests, and clumps of trees. The Don and the Oka, an affluent of the Volga, along with their respective tributaries, are the chief rivers of the government; the former traversing for a short distance its S.E. corner, the latter flowing in a curve through the central and northern parts from W. to E. Rocky heights occur on the banks of a few of the rivers, but the soil in general is composed of a thick stratum of black mould of considerable fertility. Stone, clay, marl, and lime are found in some places. North of the Oka the land is low and marshy; the climate, too, is not so healthy as that of the southern part. The summer is generally very hot, and the weather variable for a great part of the year. Cultivation is extensively carried on here. Riazan contained in 1849, 5,161,238 acres of arable land, 1,019,025 acres of meadow land, 2,508,099 acres of wood, and 1,056,088 of waste land. In the same year there were produced 51,217,538 bushels of corn, and 2,653,563 bushels of potatoes. The corn is sufficient to supply the domestic wants, and leave a surplus for exportation. Rye, wheat, oats, and barley are the kinds chiefly raised. Hemp and flax are also cultivated. There are many gardens and orchards, and culinary vegetables are much attended to. Of live stock, the government contained in 1849, 482,095 horses, 366,120 horned cattle, 603,410 sheep, 206,832 swine, and 2817 goats. A large number of bees is also kept. The most important minerals obtained here are ironstone, freestone, clay, marl, lime, and sulphur. The manufactures are neither many nor important. In 1849 the total number of factories was 122, and the number of hands employed 10,963. Among the former there were 34 of leather, 18 of tallow and candles, 14 of cloth, 11 of silk, 11 of glass and crystal, and 5 of sugar. The trade is chiefly carried on through Moscow, except for salt, which is obtained from the banks of the Volga. The inhabitants are nearly all Russians, and belong to the Greek Church, except 5133 Mohammedans, and a few Protestants, Roman Catholics, and Jews. The government is divided into twelve circles as follows:—

	Pop. (1849).		Pop. (1849).
Riazan.	135,729	Jegorjewsk ...	103,329
Saraïsk	112,490	Michailov	106,208
Kasimov	122,652	Pronsk	87,088
Skopin ...	112,637	Riashsk	98,225
Ranenbourg ..	113,480	Ssaposchok	110,303
Dankov	88,515	Sspassk	117,816
Total	1,308,472		

Riazan, the capital, stands in a broad valley at the confluence of the Lebeda with the Trubesch, an affluent of the Oka, 105 miles S.E. of Moscow. It has a cheerful appearance; the streets are broad, though but ill paved, and the houses in general well built. In the centre is a public

garden, with a handsome kiosk or pavilion. Of its twenty churches, one of which is a cathedral, none are very remarkable. There are also two convents, several schools, and various charitable institutions. The manufactures of the place include iron, glass, woollen and linen cloth, canvas, &c. Riazan is defended by a fortress, and inclosed with earthen ramparts and palisades. It is the seat of the civil governor, and of the Archbishop of Riazan and Saraïsk. The name of Riazan was conferred on this town by Catherine II. in 1777, as the former place of that name had fallen into ruins. At that time it had only 1500 inhabitants, but now the population is 21,449.

RIBALTA, **FRANCISCO**, a distinguished Spanish painter, was born at Castellon de la Plana in 1551, and studied at Valencia. His rise to eminence is connected with the following romantic anecdote:—Having succeeded in winning the heart of his master's beautiful daughter, he sought her hand from her father. The cruel reply was, that he was too great a novice in his art for such an honour. Determined to remove this objection, he set out to study in Italy, the great school of painting. Love stimulated his genius; he caught some of the finest graces of Raphael and the Carracci; and at the end of three or four years he appeared at his old master's door in Valencia, eager to show his improved artistic skill. Finding the studio empty, and seeing an unfinished picture on the easel, he quickly completed the piece, and withdrew. The old artist, on his return, was astonished to find that a master-hand had been at his painting, and still more astonished when he was told that the hand was Ribalta's; and of course was but too glad to have such a promising painter for his son-in-law. Ribalta now commenced to practise his profession with great success. His composition was tasteful and spirited, his drawing free and grand, and his colour often admirable. He combined the beauties of Domenichino and Sebastian del Piombo; and sometimes imitated Raphael so exquisitely that a picture of his was once mistaken by an Italian connoisseur for a work of the great prince of painting. The excellence of his pieces was soon recognised. Orders for religious pictures came pouring in upon him. During the rest of his life he was busily engaged in adorning the churches and convents throughout the country; and in 1628 he died, with the reputation of being one of the greatest historical painters of Spain. Many of Ribalta's works still remain to preserve his reputation. Among others, there are his masterpieces in the Collegio de Corpus at Valencia, consisting of "San Vincente de Ferrer visited on his sick-bed by our Saviour and Saints," a "Last Supper," a "Holy Family," and a "Beata." There are also "The Descent of Christ into Hades" at Segorbe, and a "Purgatory" at Castellon de la Plana. The picture of "Christ bearing the Cross," in Magdalen College, Oxford, which has been ascribed to different great artists, was identified by Mr Ford to be a Ribalta.

RIBALTA, **Juan**, the son of the preceding, was born in 1597, and studied painting under his father. His artistic powers were remarkable. He was only eighteen when he executed a "Crucifixion," which is now one of the gems of the Valencian Museum. There was no kind of subject which he did not try with success. His pictures, both of low life and of sacred story, all possessed such excellence that it was difficult to distinguish them from those of his father. In fact, he was promising to be one of the greatest of Spanish painters, when he was cut off prematurely in 1628. (See Stirling's *Artists of Spain*.)

RIBEAUVILLE (Germ. *Rappoltswiler*), a town of France, in the department of Haut-Rhin, at the foot of a beautiful valley in the Vosges, 7 miles N. of Colmar. On a hill to the west of the town stand the ruins of Ribeau-pierre or Rappoltstein, surrounded by a beautiful garden; and on the heights above is the *Herdenmauer*, or Pagan

Ribalta
Ribeauville.

Ribera

Ricardo.

Wall, a fortification of unknown origin, consisting of unhewn and uncemented stones. The chief buildings in the town are a handsome church and a town-hall. It has manufactures of cotton goods of various descriptions. Pop. 6525.

RIBERA, JOSÉ DE, called by the Italians *Il Spagnoletto* ("the Little Spaniard"), was born at Xativa, in the kingdom of Valencia, in 1598. His parents were poor; but no poverty could prevent him from studying art. While he was still very young he managed to place himself in the school of Francisco Ribalta. Not long afterwards he was found in the streets of Rome, a ragged boy, copying the frescoes on the outside of the public buildings. A benevolent cardinal took him into his house, but the wayward "little Spaniard" soon returned to his vagrant habits of study. He begged his way to Parma and Modena to examine the masterpieces of Coreggio. On his return to Rome he pawned his cloak, and with the money set out to try his fortune in Naples. Ribera had not long settled in Naples before he began to achieve great success. Assuming the severely truthful manner of Caravaggio, he employed his brush on sacred subjects with striking effect. His stern prophets and apostles, with their gaunt and shrivelled faces, and his tortured martyrs, with their agonized features and mutilated limbs, soon rivetted the public attention, and procured him many patrons. An admiring picture-dealer gave him the hand of his lovely and well-dowered daughter. The viceroy Don Pedro Giron made him the court painter, with a handsome salary. There was scarcely one of his sackcloth-girt St Jeromes and his arrow-pierced St Sebastians which did not find a ready purchaser among the churchmen. He rapidly rose towards the highest rank of Neapolitan artists. Nor did he hesitate to use villainous stratagems to accelerate his promotion. Forming a conspiracy with two other unprincipled painters, he employed every malicious art to force his rivals off the field. D'Arpino, Guido, Gessi, and Domenichino were all in turn driven from the city, and not until his accomplices had died did he cease to cheat and bully for pre-eminence. The iniquitous life of Ribera is said to have come to a dismal close. In the midst of the hey-day of his opulence and fame his daughter was seduced by Don Juan of Austria. The proud painter, broken down with shame, hid his head in privacy. At length one day he disappeared from his house, and was never heard of more. Ribera's pictures are in great repute, especially among the Spaniards and Italians. In Italy his best works are to be found at Naples, and include "St Jerome startled by the Last Trump," "Silenus and the Satyrs," "The Deposition from the Cross," "The Twelve Apostles," "Moses and Elias," and "The Last Supper." In Spain he is chiefly known by the following pictures in the museum at Madrid:—"The Martyrdom of St Bartholomew," "Jacob's Ladder," "Prometheus," "Martyrdom of St Sebastian," "Ixion on the Wheel," and a "Dead Christ lamented." (See Stirling's *Artists of Spain*, and Lanzi's *History of Painting*.)

RICARDO, DAVID, the most distinguished political economist since Adam Smith, was the third of a numerous family, and was born in the city of London on the 19th of April 1772. His father, a native of Holland, and of the Jewish persuasion, settled in this country early in life. He is said to have been a man of good talents and the strictest integrity; and having become a member of the Stock Exchange, he acquired a respectable fortune, and possessed considerable influence in his circle. David was destined for the same line of business as his father; and received, partly in England and partly at a school in Holland, where he resided two years, such an education as is usually given to young men intended for the mercantile profession.

Ricardo.

Classical learning formed no part of his early instruction. He began to be confidentially employed by his father in the business of the Stock Exchange when he was only fourteen years of age. Neither then, however, nor at any subsequent period, was he wholly engrossed by the combinations and details of his profession. From his earliest years he evinced a taste for abstract and general reasoning, and manifested that determination to probe every subject of interest to the bottom, and to form his opinion upon it according to the conviction of his mind, which was a distinguishing feature of his character.

Mr Ricardo, senior, had been accustomed to subscribe without investigation to the opinions of his ancestors on all questions connected with religion and politics, and he was desirous that his children should do the same. But this system of passive obedience and blind submission to the dictates of authority was quite repugnant to the principles of young Ricardo, who, though he did not fail to testify the sincerest affection and respect for his father, found reason to differ from him on many important points, and even to secede from the Hebrew faith.

Not long after this event, and shortly after he attained the age of majority, Ricardo formed a matrimonial union productive of much domestic happiness. But his marriage being disapproved of by his father, it occasioned, with the change in his religion, a breach between them. Being thus thrown wholly on his own resources, he commenced business for himself. At this important epoch of his history the oldest and most respectable members of the Stock Exchange gave a striking proof of the high esteem entertained by them for his talents and the integrity of his character, by voluntarily coming forward to support him in his undertakings. His success exceeded the most sanguine expectations of his friends, and in a few years he realized an ample fortune.

"The talent for obtaining wealth," says a near relation of Ricardo's, from whose interesting account of his life we have borrowed these particulars, "is not held in much estimation; but perhaps in nothing did Ricardo more evince his extraordinary powers than he did in his business. His complete knowledge of all its intricacies; his surprising quickness at figures and calculation; his capability of getting through, without any apparent exertion, the immense transactions in which he was concerned; his coolness and judgment, combined certainly with (for him) a fortunate tissue of public events, enabled him to leave all his contemporaries at the Stock Exchange far behind, and to raise himself infinitely higher, not only in fortune, but in general character and estimation, than any man had ever done before in that house. Such was the impression which these qualities had made on his competitors that several of the most discerning among them, long before he had emerged into public notoriety, prognosticated, in their admiration, that he would live to fill some of the highest stations in the state."¹

According as his solicitude about his success in life declined, Ricardo began to devote a greater portion of his time to scientific and literary pursuits. When about twenty-five years of age he began to study some branches of mathematical science, and made considerable progress in chemistry and mineralogy. He fitted up a laboratory, formed a collection of minerals, and was one of the original members of the Geological Society. It is known, however, that he never entered warmly into the investigation of these sciences. They were not adapted to the peculiar cast of his mind; and he abandoned them entirely as soon as his attention was directed to the more congenial study of political economy.

He is stated to have made his first acquaintance with the

¹ See an account of the life of Ricardo in the *Annual Obituary* for 1823, supposed to be written by one of his brothers.

Ricardo. *Wealth of Nations* in 1799, while on a visit to Bath. He was highly gratified by its perusal; and it is most probable that the inquiries about which it is conversant continued henceforth to occupy a considerable share of his attention, though it was not till a later period that his spare time became almost exclusively occupied with their study.

Ricardo commenced his career as an author in 1809. The rise in the market-price of bullion, and the fall of the exchange which had taken place that year, excited a good deal of attention. Ricardo applied himself to the consideration of the subject; and the studies in which he had been latterly engaged, combined with the experience derived from his money transactions, enabled him not only to perceive the true cause of the phenomena in question, but to trace and exhibit its practical bearing and effect. When he began this investigation, he had no intention of laying the result of his researches before the public. But having shown his manuscript to Mr Perry, the proprietor and editor of the *Morning Chronicle*, he was prevailed upon by him, though not without considerable difficulty, to consent to its publication, in the shape of letters, in that journal. The first of these appeared on the 6th of September 1809. They made a considerable impression, and elicited various answers. This success, and the increasing interest of the subject, induced him to submit his opinions upon it to the judgment of the public, in a more enlarged and systematic form, in the celebrated tract entitled *The High Price of Bullion a Proof of the Depreciation of Bank-Notes*, which led the way in the far-famed bullion controversy. It issued from the press several months previously to the appointment of the Bullion Committee, and is believed to have had no inconsiderable effect in forwarding that important measure. In this tract Ricardo showed that redundancy and deficiency of currency are only relative terms; and that so long as the currency of a particular country consists exclusively of gold and silver coins, or of paper convertible into them, it is impossible that its value should either rise above or fall below the value of the currencies of other countries by a greater sum than will suffice to defray the expense of importing foreign coin or bullion if the currency be deficient, or of exporting a portion of the existing supply if it be redundant. But when a country issues inconvertible paper-notes, as was then the case in England, they cannot be exported to other countries in the event of their becoming relatively redundant at home; and whenever, therefore, the exchange with foreign states is depressed below, or the price of bullion rises above its mint price, more than the expense of sending coin or bullion abroad, it is a conclusive proof that too much paper has been issued, and that its value is *depreciated from excess*. The principles which pervade the report of the Bullion Committee are substantially the same with those established by Ricardo in this pamphlet. But the more comprehensive and popular manner in which they are illustrated in the report, and their being recommended by a committee composed of some of the ablest members of the House of Commons, gave them a weight and authority which they could not otherwise have obtained. And though the prejudices and ignorance of some, and the interested, and therefore determined opposition of others, prevented for a while the adoption of the measures proposed by Ricardo and the committee for restoring the currency to a sound and healthy state, they have since been carried into full effect; and afford one of the most memorable and encouraging examples in the history of the country of the triumph of principle over selfishness, sophistry, and error.

The fourth edition of this tract is the most valuable.

An appendix added to it has some acute observations on certain disputed questions in the theory of exchange; and it also contains the first germ of the original idea of making bank-notes exchangeable for bars of gold bullion.

Among those who entered the lists in opposition to the principles laid down and the practical measures suggested in this tract, and in the report of the Bullion Committee, a prominent place is due to Mr Bosanquet. This gentleman had great experience as a merchant; and as he professes that the statements in his *Practical Observations on the Bullion Report*, which are completely at variance with those in the latter, were the result of a careful examination of the theoretical opinions of the committee by the test of fact and experiment, they were well calculated to make, and did make, a very considerable impression. The triumph of Bosanquet and his friends was, however, of very short duration. Ricardo did not hesitate to attack this formidable adversary in his stronghold. His second tract, entitled *Reply to Mr Bosanquet's Practical Observations on the Report of the Bullion Committee* was published in 1811, and is perhaps the best controversial essay that has ever appeared on any disputed question of political economy. In this pamphlet Ricardo met Bosanquet on his own ground, and overthrew him with his own weapons. He examined the proofs which the latter had brought forward of the pretended discrepancy between the facts stated in his own tract, which he said were consistent with experience, and the theory laid down in the Bullion Report; and showed that Bosanquet had either mistaken the cases by which he proposed to test the theory, or that the discrepancy was apparent only, and was entirely a consequence of his inability to apply the principle, and not of any deficiency in the principle itself. The victory of Ricardo was perfect and complete; and the elaborate errors and mis-statements of Bosanquet served only, in the language of Dr Copleston, "to illustrate the abilities of the writer who stepped forward to vindicate the truth."¹

This tract affords a striking example of the ascendancy which those who possess a knowledge both of principle and practice have over those familiar only with the latter. And though the interest of the question which gave rise to it be now subsided, it will always be read with delight by such as are not insensible of the high gratification which all ingenuous minds must feel in observing the ease with which a superior intellect clears away the irrelevant matter with which a question has been designedly embarrassed, reduces false facts to their just value, and traces and exhibits the constant operation of the same general principle through all the mazy intricacies of practical detail.

The merit of these pamphlets was duly appreciated, and Ricardo's society was in consequence courted by men of the first eminence and consideration, who were not less delighted with his modesty, and the mildness and amenity of his manners, than with the reach and vigour of his understanding. It was at this period that he formed that intimacy with Mr Malthus and Mr Mill, the author of the *History of British India*, which ended only with his life. To Mill he was particularly attached; and he always felt pleasure in acknowledging how much he owed to his friendship.

Ricardo's next appearance as an author was in 1815, during the discussions on the bill afterwards passed into a law, for raising the limit at which the importation of foreign corn should be permitted to 80s. Malthus and a "Fellow of University College, Oxford" (Mr, afterwards Sir Edward, West), had in two able pamphlets, published almost at the same moment, developed the real nature,

Ricardo.

¹ First Letter to the Right Hon. Sir Robert Peel, by one of his Constituents, p. 61.

Ricardo. origin, and causes of rent.¹ But neither of them perceived the real value and importance of the principles which he had established. This was reserved for Mr Ricardo, who, in his *Essay on the Influence of a Low Price of Corn on the Profits of Stock*, showed the effect of that increase in the price of raw produce, which always takes place in the progress of society, on wages and profits; and founded a cogent argument in favour of the freedom of the corn-trade on the very principles from which Malthus had vainly endeavoured to show the propriety of subjecting it to fresh restrictions.

In 1816 Ricardo published his *Proposals for an Economical and Secure Currency, with Observations on the Profits of the Bank of England*. In this pamphlet he examined the circumstances which determine the value of money, both when all individuals have the power to supply it, and when that power is restricted and placed under a monopoly; and he showed that in the former case its value depends, like that of all freely-supplied articles, on its cost, while in the latter its value is quite unaffected by that circumstance, and depends entirely on the extent to which it may be issued compared with the demand. This is a principle of great importance; for it shows that intrinsic worth is not necessary to a currency, and that, provided the supply of paper-notes declared to be legal tender be sufficiently limited, their value may be maintained on a par with that of gold, or raised to any higher level. If, therefore, it were practicable to devise a plan for preserving the value of paper on a level with gold, without making it convertible into coin at the pleasure of the holder, the whole expense attending the use of a metallic currency would be saved. To effect this object, Ricardo proposed that bank-notes, instead of being made exchangeable for gold coins, should be made exchangeable for *bars of gold bullion of the standard weight and purity*. This device was obviously calculated to check the over-issue of paper quite as effectually as it is checked by making it convertible into coin; while, as the bars could not be used as currency, it prevented any gold from getting into circulation, and saved the expense of coinage, and of the wear and tear of the coins. Ricardo's proposal was recommended by the committees of the House of Lords and Commons appointed in 1819 to consider the expediency of the Bank of England resuming cash payments, and was adopted in the bill for their resumption introduced by Sir Robert Peel. Inasmuch, however, as it required that the place of sovereigns should be filled with L.1 notes, the forgery of the latter began to be extensively carried on; and it was judged better to incur the expense of recurring to and keeping up a mixed currency, than to continue a plan which, though productive of a large saving, held out an all but irresistible temptation to crime.

In 1817 Ricardo published his great work on the *Principles of Political Economy and Taxation*. This was a step which he did not take without much hesitation. He was not, and did not affect to be, insensible of the value of literary and philosophical reputation, but his modesty always led him to undervalue his own powers; and having already attained to a very high degree of celebrity as a writer on currency, he was unwilling to risk what he already possessed by attempting to gain more. Ultimately, however, he was prevailed upon by the entreaties of his friends to allow his work to be sent to press. Its appearance forms a new era in the history of political science. With the exception of the *Wealth of Nations*, it is the most important, as it certainly is the most original and profound work that has appeared on political economy. But the brevity with

which he has stated some of his peculiar doctrines, the fewness of his illustrations, and the mathematical cast of his reasonings, are apt to repel ordinary readers, and give an appearance of obscurity to the work. But those who study it with the attention which it so well deserves will find that it is eminently logical. And the powers of mind displayed in its investigations, the dexterity with which the most abstruse and difficult questions are unravelled, the sagacity evinced in tracing the operation of general principles, in disentangling them from such as are of a secondary or accidental nature, and in perceiving and estimating their remotest consequences, have rarely been surpassed, and will for ever secure the name of Ricardo a conspicuous place in the list of profound thinkers, and of the discoverers of useful truths.

The reader will find in the article *POLITICAL ECONOMY* a pretty full account of the leading principles advanced by Ricardo, and of his most material conclusions. It is to be regretted that he relied too much on theoretical reasonings, without making sufficient allowance for the circumstances natural to and inherent in society, which either counteract or materially modify some of the principles on which he laid the greatest stress. But despite the errors into which he thus necessarily fell, his work is of the highest value. It is the first in which we find an analysis and generally just explanation of the circumstances which determine the distribution of wealth among the various ranks and orders of society, and which govern their apparently conflicting but really harmonious relations. Since the appearance of Ricardo's work the whole face of the science has been changed, not merely by his numerous discoveries, and the new lights which he struck out in every department, but by the closer and more analytical method of reasoning which he introduced. In this respect there is yet, no doubt, much room for improvement; but any one who compares the economical writings of the last thirty years with those current before Ricardo's work made its appearance will be satisfied that there is now much less of loose generalization, and more regard to science and principle. The practical considerations which Ricardo too much neglected have had their influence ascertained by subsequent inquirers; and his doctrines having been properly modified, and made applicable to the exigencies of society, have acquired a high practical as well as theoretical value.

Previously to the publication of his *Principles*, Ricardo had retired from business, possessed of a large fortune, acquired with the universal respect and esteem of his competitors. He afterwards spent the greater part of the summers at Gatcomb Park, an estate which he had purchased in Gloucestershire. But he did not retire from the bustle of active life to the mere enjoyment of his acres—*Non fuit consilium socordia atque desidra bonum otium contereere*. He had other objects in view; and while his leisure hours, when in the country, were chiefly devoted to the prosecution of the interesting science of which he was now confessedly at the head, he determined to extend the sphere of his usefulness by entering the House of Commons. In 1819 he took his seat as member for Portarlington. His diffidence had, however, nearly deprived the country of the important services which he rendered in this situation. In a letter to one of his friends, dated the 7th of April 1819, he says:—"You will have seen that I have taken my seat in the House of Commons. I fear that I shall be of little use there. I have twice attempted to speak; but I proceeded in the most embarrassed manner, and I have no hope of conquering the alarm with which I

¹ There was little that was new in either of these pamphlets; the origin, nature, and causes of rent having been quite as well, or better, explained in a pamphlet by Dr Anderson, the editor of the *Bee*, published in 1777 (*Inquiry into the Nature of the Corn-Laws*), and in his *Agricultural Recreations*, published in 1801. But the investigations and discoveries of Anderson did not attract any attention, and were, indeed, totally forgotten; so that it was necessary the theory of rent should be re-stated (it is said to have been re-discovered), to make it be understood and appreciated by the public.

Ricardo. am assailed the moment I hear the sound of my own voice." And in a letter to the same gentleman, dated the 22d of June 1819, he says: "I thank you for your endeavours to inspire me with confidence on the occasion of my addressing the House. Their indulgent reception of me has in some degree made the task of speaking more easy to me; but there are yet so many formidable obstacles to my success, and some, I fear, of a nature nearly insurmountable, that I apprehend it will be wisdom and sound discretion in me to content myself with giving silent votes." Fortunately he did not adopt this resolution. The difficulties with which he had at first to struggle, and his diffidence in himself, gradually subsided; while the mildness of his manners, his mastery over the subjects on which he spoke, and his undoubted integrity, speedily secured him a very extensive influence both in the House and the country, and gave great weight and authority to his opinions.

Ricardo was not one of those who make speeches to suit the ephemeral circumstances and politics of the day. He spoke only from principle, and with a fixed resolution not to diverge in any degree from the path which it pointed out; he neither concealed nor modified opinions for the purpose of conciliating the favour, or of disarming the prejudices or hostility, of any man or set of men; nor did he ever make a speech or give a vote which he did not believe to be founded on just principles, and calculated to promote the lasting interests of the public. Trained to habits of profound thinking, independent in his fortune and inflexible in his principles, Ricardo had nothing in common with mere party politicians. The public good was the grand object of his parliamentary exertions; and he laboured to promote it not by engaging in party combinations, but by supporting the rights and liberties of all classes, and by unfolding the true sources of national wealth and general prosperity.

The change which has taken place in the public opinion respecting the financial and commercial policy of the country, since the period when Ricardo obtained a seat in the House of Commons, is as complete as it is gratifying. The most enlarged views are now supported by the leading members of both Houses. The protective system has no longer a single parliamentary supporter of eminence. All are now ready to admit that it is founded on vicious principles; that it has retarded the progress of those nations by whom it has been adopted; and that it is sound policy to admit the freest competition in every branch of industry, and to deal fairly and liberally with all the world. The writings and speeches of Ricardo contributed in no ordinary degree to accomplish this salutary and desirable change. As he was known to be a master of economical science, his opinion, from the moment he entered the House of Commons, was referred to on all important occasions;¹ and he acquired a constant accession of influence and consideration, according as experience served to render the House and the country better acquainted with his talents and his singleness of purpose.

In 1820 he contributed an article on the FUNDING SYSTEM for the *Encyclopædia Britannica*. He was a decided friend to the plan for raising the supplies for a war within the year, by an equivalent increase of taxation; and he was also of opinion that it would be both expedient and practicable to pay off the public debt by an assessment on capital. In this article he has endeavoured, if not with perfect success, at least with considerable ingenuity, to defend both projects from the objections commonly urged against them.

In 1822, during the parliamentary discussions on the subject of the corn laws, Ricardo published his pamphlet on *Protection to Agriculture*. This is the best of all his pamphlets, and is indeed a *chef-d'œuvre*. The questions respecting remunerating price, the influence of a low and

high value of corn on wages and profits, the effects of taxation on agriculture and manufactures, and many other topics of equal difficulty and interest, are all discussed in the short compass of eighty or ninety pages, with a precision and clearness that leaves little or nothing to be desired. Had he never written anything else, this pamphlet would have placed Ricardo in the first rank of political economists.

Though not robust, Ricardo's constitution was apparently good, and his health such as to promise a long life of usefulness. He had indeed been subject for several years to an affection in one of his ears; but as it had not given him any serious inconvenience, he paid it but little attention. When he retired to his seat in Gloucestershire, subsequently to the close of the session of 1823, he was in excellent health and spirits; and besides completing a tract, containing a plan for the establishment of a National Bank, he had engaged, with his usual ardour, in profound and elaborate inquiries in relation to the theory of value. But he was not destined to bring these inquiries to a close! In the beginning of September he was suddenly seized with a violent pain in the diseased ear; the symptoms were not, however, considered unfavourable; and the breaking of an imposthume that had formed within the ear contributed greatly to his relief. But the amendment was only transitory; within two days inflammation re-commenced; and after a period of indescribable agony, pressure on the brain ensued, which produced a stupor that continued until death terminated his sufferings on the 11th of September, in his fifty-second year.

In private life Ricardo was most amiable. He was a kind and indulgent father and husband, and an affectionate and zealous friend. No man could be more thoroughly free from every species of artifice and pretension, more sincere, plain, and unassuming. He was particularly fond of assembling intelligent men around him, and of conversing in the most unrestrained manner on all topics of interest, but more especially on those connected with his favourite science. He was always ready to give way to others, and never discovered the least impatience to speak; but when he did speak, the extent and accuracy of his knowledge, the solidity of his judgment, his perfect candour, and his peculiar talent for resolving a question into its elements, and for setting the most difficult and complicated subject in the clearest point of view, arrested the attention of every one, and delighted all who heard him. He never entered into an argument, whether in public or private, for the sake of displaying ingenuity, baffling an opponent, or gaining a victory. The discovery of truth was his exclusive object. He was ever open to conviction; and if he were satisfied that he had either advanced or supported an erroneous opinion, he was the first to acknowledge his error, and to caution others against it.

Few men have possessed in a higher degree than Ricardo the talent of speaking and conversing with clearness and facility on the abstrusest topics. In this respect his speeches were greatly superior to his publications. The latter cannot be readily understood and followed without considerable attention; but nothing could exceed the ease and felicity with which he illustrated and explained the most difficult questions of political economy, both in private conversation and in his speeches. Without being forcible, his style of speaking was easy, fluent, and agreeable. It was impossible to take him off his guard. To those who were not familiar with his speculations, some of his positions were apt to appear paradoxical; but the paradox was only in appearance. He seldom advanced an opinion on which he had not deeply reflected, and without examining it in every point of view. And the readiness with which he met and

¹ Mr Ricardo made the first of his prominent appearances on the 24th of May 1819, in the debate on the resolutions proposed by Mr (Sir Robert) Peel respecting the resumption of cash payments. He did not rise until he was loudly called upon from all sides of the House.

Ricaut.

overthrew the most specious objections that the ablest men in the House could state to his doctrines, is the best proof of their correctness, and of the superiority of his understanding. That there were greater orators, and men of more varied and general acquirements, in Parliament than Ricardo, we readily allow; but we are bold to say, that in point of deep, clear, and comprehensive intellect, he had no superiors, and very few, if any equals, either in Parliament or the country.

Ricardo was not less generous than intelligent; he was never slow to come forward to the relief of the poor and the distressed; and while he contributed to almost every charitable institution in the metropolis, he supported at his own expense an alms-house for the poor, and two schools for the instruction of the young in the vicinity of his seat in the country.

Besides the publications previously enumerated, Ricardo left one or two manuscripts. Among others, a *Plan for the Establishment of a National Bank* was found in a finished state, and has since been published. He also left Notes on Malthus's *Principles of Political Economy*, containing a vindication of his own doctrines from the objections of Malthus, and showing the mistakes into which he conceived the latter had fallen.

Though not properly belonging to the Whig party, Ricardo voted almost uniformly with them. He was impressed with the conviction that many advantages would result from giving the people a greater influence over the choice of their representatives in the House of Commons than they then possessed; and he was so far a friend to the system of the radical reformers as to give his cordial support to the plan of voting by ballot, which he considered as the best if not the only means for securing the mass of the electors against improper solicitations, and for enabling them to vote in favour of the candidates whom they really approved. He did not, however, agree with the radical reformers in their plan of universal suffrage: he thought the elective franchise should be given to all who possessed a certain amount of property; but he was of opinion that, while it would be a very hazardous experiment, no practical good would result from giving the franchise indiscriminately to all.

When the circumstances under which Ricardo spent the greater part of his life are brought under view, and when it is also recollected that he died at the early age of fifty-one, it may be truly said that very few men have achieved so much. His industry was as remarkable as his sagacity and his candour.

"The history of Ricardo," to use the words of his friend Mill, "holds out a bright and inspiring example. Ricardo had everything to do for himself, and he did everything. Let not the generous youth, whose aspirations are higher than his circumstances despair of attaining either the highest intellectual excellence, or the highest influence on the welfare of his species, when he recollects in what circumstances Ricardo opened and in what he closed his memorable life. He had his fortune to make, his mind to form; he had even his education to commence and conduct. In a field of the most intense competition he realized a large fortune, with the universal esteem and affection of those who could best judge of the honour and purity of his acts. Amid this scene of active exertion and practical detail, he cultivated and he acquired habits of intense and patient and comprehensive thinking, such as have been rarely equalled and never excelled."

The works of Ricardo have been collected and published, with a notice of his life, in an 8vo volume, by the author of this article. (J. R. M.)

RICAUT, or RYCAUT, SIR PAUL, an English traveller and diplomatist of the time of whose birth we find no account. He studied at Cambridge, where he received his bachelor's degree in 1650; and in 1661 he was appointed secretary to the Earl of Winchelsea, who was sent ambas-

sador extraordinary to Turkey. During his continuance in that station he wrote *The Present State of the Ottoman Empire*, in three books, London, 1670; and he afterwards resided eleven years as consul at Smyrna, where at the command of Charles II., he composed *The Present State of the Greek and Armenian Churches*, 1678. On his return, Lord Clarendon being appointed lord-lieutenant of Ireland in 1685, made him his principal secretary for Leinster and Connaught. King James II. knighted him, and made him one of the privy council in Ireland, and judge of the Court of Admiralty. These appointments he held till the Revolution. He was employed by King William as resident at the Hanse Towns in Lower Saxony, where he continued for ten years; but being worn out with age and infirmities, he obtained leave to return in 1700, and died in London on the 16th December of the same year. Ricaut continued Knolles's *History of the Turks*, 1680, and Platina's *Lives of the Popes*, 1685. There are likewise some other publications which bear his name.

RICCI, or RIZZI, SEBASTIANO, a famous Italian painter, was born at Cival di Belluno, in the Venetian state, about 1660. It was his good fortune to go through a thorough course of training. He first studied under Cervelli at Venice and Milan. He then travelled through Italy, familiarizing his hand in executing commissions. Lastly, he visited Germany, England, and Flanders, perfecting his notions of art by a close study of the different schools. The result of this excellent education was seen after Ricci had settled at Venice. While he was painting, many of the beauties of the great masters which he had seen occurred opportunely to his mind. Without servilely copying, he put them down upon his canvas. Accordingly his pictures came forth to the world exhibiting several different styles, and the excellences of several different artists. Ricci died in 1734. (See Lanzi's *History of Painting*.)

RICCIARELLI, DANIELE, an Italian artist, generally called, from the place of his birth, *Daniele di Volterra*, was born in 1509, and studied painting under Razzi and Peruzzi. The young artist, settling in Rome, strove most unweariedly to attain eminence in his profession. No efforts were spared on his pictures. He proceeded with a careful slowness, attempting to reach his ideal by a close imitation of Michael Angelo. It is even said that he sometimes in a difficulty had recourse to the more direct aid of that great master's own hand. The result of this earnest labour was, that Ricciarelli obtained abundant encouragement. His constant friend, Michael Angelo, recommended him on all possible occasions. He had the honour to beautify with works of art a chapel in the church of the Trinità, to paint in the Farnese Palace, to execute certain decorations in the Palazzo de' Medici at Navona, and to begin the stucco-work and the pictures in the Hall of the Kings. Nor was he less highly patronized when, towards the close of his life, he turned his attention to statuary. His last work was a bronze horse, intended for an equestrian statue of Henry II. of France. Ricciarelli died in 1566. The principal extant works of Ricciarelli are at Rome. These are a "St John the Baptist" in the picture gallery of the Capitol, a "Saviour bearing the Cross" in the Palazzo Rospigliosi, and a "Descent from the Cross," his masterpiece, in the church of Trinità de' Monti. There is also an "Elijah" at Volterra. (See Vasari's *Painters*, and Lanzi's *History of Painting*.)

RICCIOLI, GIOVANNI BATTISTA, an eminent astronomer, was born at Ferrara in 1598, entered the Society of the Jesuits in 1614, and died in 1671. (See DISSERTATION FOURTH, § iv.; and ASTRONOMY, *History of*.)

RICE, the seed of *Oryza sativa* (Linn.), a beautiful tropical grass (*Graminaceæ*), believed to be originally a native of some part of India. It is now extensively cultivated in the East Indies, China, parts of Africa and Southern Europe,

Ricci
||
Rice.

Rice. and in tropical America. Rice is second in importance only to wheat as an article of human food, and forms the chief nutriment of at least a third of mankind. Marsden, in his *History of Sumatra*, says it is "the grand material of food on which a hundred millions of the inhabitants of the earth subsist." It is admirably adapted to the wants of the inhabitants of the tropics, as it is not so heating to the human system as any of the other cereals, and it is almost a cure for diarrhoea and dysentery, which are so prevalent in warm climates.

Rice was known to the ancients, and is described under the name of *Opvčov* by Theophrastus, *Opvča* by Dioscorides, and *Oryza* by Pliny. The last-mentioned author, from the description given in his *Natural History*, appears to have been quite ignorant of the plant, or else mistaken in the grain altogether, for he describes it as a bulbous-rooted plant, with thick, fleshy leaves and purple blossoms. In its native country (India), rice has most probably been cultivated from the earliest times. It is naturally a marsh plant, and consequently requires a damp soil and a moist atmosphere; it is there usually cultivated in low lands, which are either naturally liable to be flooded, or which admit of easy and copious irrigation. There are, however, varieties cultivated which endure a much drier soil, and are adapted for hill culture. The upland or hill rice is smaller in grain and less valuable; but it is nevertheless cultivated in great quantities, the manure employed being chiefly the dung of animals mixed with wood-ashes. In India the varieties of rice are very numerous. No less than one hundred and sixty-one are enumerated in Moon's *Catalogue of Ceylon Plants* as being known in that island.

The finest rice in the world is that raised in North and South Carolina, in the United States, where the prevalence of swampy lands and a rich vegetable soil render its cultivation easy and very profitable. The rice of Carolina is remarkable for its pure white colour and large size; and as it contains a considerable proportion of gluten, it is most valued as an article of food. Rice in the husk is generally called *paddy*. In this state it is largely imported into Great Britain and husked at the rice-cleaning mills, which are now established in all our large ports: when kept in the husk, it is said to retain its vitality for many years.

The cultivation of this cereal is very much varied by the circumstances of the locality in which it is grown: in many places it is scattered over the land whilst still flooded, and as it sinks and settles in the mud it speedily germinates, and springs up as soon as the land is uncovered: in other places buffaloes are driven over the muddy surface as soon as the floods have retired, and a few grains are placed in each foot-mark, the rice often being made to germinate before being placed in the holes. Two crops of flooded rice are obtained annually in India; the first is cut in February and March, the second is reaped in October. The earlier one is by far the most valuable.

The quantity of rice consumed in this country, and in Europe generally, is very large; our imports in 1858 were, — of husked rice, 206,000 tons; and of unhusked rice, or paddy, 33,601 quarters.

Canadian Rice is the seed of *Zizania aquatica*, Hort. Kew (Nat. Ord. *Graminaceæ*). It grows on the margins of shallow streams and running waters, and produces an abundance of wholesome farinaceous grain. It is called in Canada *lake rice*, *tuscarora*, or *mahnomonee*; and is found in shallow waters from Florida to the Canadian lakes. It is regularly harvested by the Indians, this work being chiefly performed by their squaws; but it is not gathered in any quantity by the white population, although it is esteemed a great delicacy. It has been tried in this country, and it is likely that it would succeed if it should become an object of demand; and as it is aquatic, it can be cheaply cultivated.

(T. C. A.)

RICH, CLAUDIUS JAMES, a distinguished traveller and scholar, was born in 1787 near Dijon in Burgundy, and having been removed to England, was brought up at Bristol. His youth was characterised by an extraordinary aptitude for languages. When a mere child he picked up a knowledge of several modern tongues. At the age of nine he sat down to decipher some Arabic manuscripts, with no other aid than a grammar and dictionary. Not long afterwards he was reading Hebrew, Syriac, Persian, and Turkish. The boy, in fact, became such a remarkable orientalist that in 1804 the East India Directors despatched him to a writership in Bombay, and at the same time gave him permission to make any delays on the road for the purpose of increasing his knowledge. Rich took care to avail himself of this privilege to the utmost. As he sailed along the Mediterranean he formed the resolution of imbuing himself thoroughly with eastern manners and attainments. Placing himself in a school at Smyrna, he soon became metamorphosed into a young Turk. Then repairing to Alexandria, he began to acquire the language and martial accomplishments of a wild Arab. At the end of a year or two he had become so complete an orientalist that he set out in the disguise of a Mameluke to travel over land to the Persian Gulf. Nor was this difficult impersonation unsuccessful. He wandered over a great part of Palestine and Syria, entered the grand mosque at Damascus along with the Mohammedan pilgrims, and arrived at Bussora without ever having been challenged for a Christian. Rich's good fortune attended him to Bombay. On his arrival there in 1807, Sir James Mackintosh welcomed him to his house. A few months afterwards the eldest daughter of that philosopher bestowed upon him her hand. His abilities continued to attract interest, until in 1808 he was appointed resident at Bagdad. A wide field of investigation was now opened up to the ever-active and all-observant mind of Rich. He set himself, with characteristic enthusiasm, to make a sweeping survey of the district. Every research that could increase human knowledge was undertaken. The geography, history, manners, and statistics of the country were studied. Oriental manuscripts were collected from all quarters. Ancient medals, coins, and gems were picked up from among the remains of Nineveh and Ctesiphon. The ruins of Babylon were repeatedly explored, and his discoveries published in the form of two memoirs. Even astronomical observations were taken with all the enthusiasm and success of a professed mathematician. He had in fact amassed a most wonderful amount of multifarious knowledge, when he was cut off by the cholera at Shiraz on the 5th of October 1821. Rich's *Narrative of a Residence in Koordistan*, accompanied by a short memoir, was published by his widow, in 2 vols., London, 1836. His valuable collection of oriental MSS., coins, and antiquities, is now in the British Museum.

RICHARD, the name of three English kings. Richard I., surnamed *Cœur de Lion* (the "Lion-hearted"), was born in 1157, succeeded his father Henry II. in 1189, and was killed by an arrow at the siege of the castle of Chaluz in 1199. Richard II., the son of the Black Prince, was born in 1366, succeeded his grandfather Edward III. in 1377, was deposed by Bolingbroke in 1399, and is said to have been put to death in Pontefract Castle in 1400. Richard III., the son of Richard, Duke of York, was born in 1452, usurped the crown from his nephew Edward V. in 1483, and was slain on Bosworth field in 1485. (See ENGLAND.)

RICHARD DE BURY, a learned English statesman, was born at Bury St Edmunds in 1287, and was educated at Oxford. A bright career of preferment was early opened up before him. Scarcely had he finished his studies before he was appointed tutor to the Prince of Wales (afterwards Edward III.) The devoted manner in which this office was discharged was the means of accelerating his rise. No

sooner had his pupil succeeded to the throne than a shower of dignities, both civil and ecclesiastical, began to fall upon his head. He was made treasurer of the wardrobe and clerk of the privy seal. The revenues of many rich benefices were placed at his disposal. He was twice despatched to Rome with a splendid retinue as legate to Pope John XXII. At length he reached the climax of his good fortune by being appointed bishop of Durham in 1333, and treasurer and high chancellor of England in 1334. Richard adorned this high station by appearing as an enthusiastic and enlightened lover of books. In the course of his travels he had devoted both his time and his money to the collecting of literary works. It now became the congenial task of his declining years to complete his collection. Every library in the kingdom was examined in quest of new treasures. Those that could be bought he purchased. Those that could only be borrowed he caused to be copied by men who were kept in his palace expressly for that purpose. Thus did he procure a splendid assortment of books, which, at his death in 1345, he bequeathed to that hall at Oxford which is now called Trinity College. Richard de Bury left a treatise upon his own book-collecting labours, entitled *Philobiblon*. It was published at Cologne in 1473, at Spire in 1483, at Paris in 1500, and at Oxford in 1599. An English translation by Mr J. B. Inglis was published in 1832. (See *English Cyclopædia of Biography*.)

RICHARD OF CIRENCESTER, an old monkish historian, was born in the beginning of the fourteenth century at Cirencester in Gloucestershire, and entered the Benedictine monastery of St Peter, Westminster, in 1350. During his leisure hours in the cloister he addressed himself to the study of British history and antiquities. To perfect his information, he is said to have explored all the different libraries in England. The chief result of his labour and investigation began to appear in the form of a treatise, *De Situ Britannie*. The body of the matter was compiled from Cæsar and other classical authors. The Itinerary he professed to have taken chiefly from certain fragments left by a Roman general. The work was proceeding successfully when the author met with an interruption. His ecclesiastical superior the abbot found fault with him for wasting his consecrated time upon such secular pursuits. He indeed vindicated his conduct in an enlightened and spirited manner; but he felt himself obliged to bow to authority, and to bring his book to a premature close. The death of Richard is supposed to have taken place about 1401. The above-mentioned work was discovered in 1747, and published in 1757 by Charles Julius Bertram, professor of English in the Royal Marine Academy at Copenhagen. An English translation appeared in 1848, forming, along with five other old English chronicles, a volume of Bohn's "Antiquarian Library." Richard of Cirencester is also the author of the following unpublished works:—*Historia ab Hengisto ad Ann. 1348*, the former part of which is in the public library of the university of Cambridge; and *Tractatus super Symbolum Majus et Minus*; and *Liber de Officiis Ecclesiasticis*, both in the Peterborough library.

RICHARDSON, JONATHAN, a portrait-painter of some note, was born about the year 1665, and against his inclination was placed by his father-in-law apprentice to a scrivener, with whom he lived six years. Having obtained his freedom by the death of his master, he followed the bent of his disposition, and at the age of twenty became the disciple of Riley, with whom he lived four years, whose niece he married, and of whose manner he acquired enough to maintain a solid and lasting reputation, even during the lives of Kneller and Dahl, and to remain at the head of the profession when they no longer continued to exercise it. The following characterisation of Richardson is by the author of the *Anecdotes*.

Richard-
son.

"There is strength, roundness, and boldness in his colouring; but his men want dignity, and his women grace. The good sense of the nation is characterised in his portraits. We perceive that he lived in an age when neither enthusiasm nor servility was predominant. Yet with a pencil so firm, possessed of a numerous and excellent collection of drawings, full of the theory and profound in reflection of his art, he drew nothing well below the head, and was void of imagination. His attitudes, draperies, and backgrounds are totally insipid and unmeaning; so ill did he apply to his own practice the sagacious rules and hints which he bestowed on others. Though he wrote with fire and judgment, his paintings owed little to either. No man dived deeper into the inexhaustible stores of Raphael, or was more smitten with the native lustre of Vandyck. Yet though capable of relishing the elevation of the one and the elegance of the other, he could never contrive to see with their eyes when he was to copy nature himself. One wonders that he could comment on their works so well, and imitate them so little." He quitted business some years before his death; but his temperance and virtue contributed to protract his life to a great length in the full enjoyment of his understanding, and in the felicity of domestic friendship. He died suddenly at his house in Queen's Square, on the 28th of May 1745, in his eighty-first year. In 1719 Richardson published two discourses: *An Essay on the whole Art of Criticism as it relates to Painting*; *An Argument in behalf of the Science of a Connoisseur*. In 1722 there appeared *An Account of some of the Statues, Bas-reliefs, Drawings, and Paintings in Italy, &c.*, with Remarks by Messrs Richardson, senior and junior. His son made the journey; and from his notes, letters, and observations, they both at his return compiled this valuable work.

RICHARDSON, Samuel, a distinguished novelist, was born in the year 1689, in Derbyshire. His father, the descendant of a reputable family in the county of Surrey, followed the occupation of a joiner. The son was at first intended for the church; but after his father had sustained some heavy losses he was left, at the age of fifteen or sixteen, to make choice of some employment which did not require so expensive a preparation. He only appears to have received the most ordinary training of a country school. He was a bashful boy, and gave an early preference to the society of the other sex. From his childhood he delighted in letter-writing; and to this early taste we may trace the germ of his principal works. "I was not more than thirteen," he informs us, "when three of these young women, unknown to each other, having an high opinion of my taciturnity, revealed to me their love secrets, in order to induce me to give them copies to write, alter, or correct, for answers to their lovers' letters; nor did any one of them ever know that I was the secretary to the others." In 1706 he was bound apprentice to John Wilde, a printer at Stationers' Hall, London. Although he served a rigid master, he contrived to steal from his hours of rest and relaxation some precious intervals for the improvement of his mind. After the completion of his apprenticeship he continued for five or six years to work as a compositor and corrector in a printing-office, and part of this time as an overseer. Thus he gradually arose to the situation of a master-printer, having first taken an office in a court in Fleet Street, and afterwards in Salisbury Court. As an apprentice he had been diligent and conscientious, as a master he was assiduous and liberal. In addition to the proper avocations of a printer, he on various occasions undertook to write indices, prefaces, and, as he describes them, honest dedications. The punctuality, together with the integrity and liberality of his dealings, speedily procured him friends, and his business became very prosperous. Through the interest of Mr Speaker Onslow, he was em-

Richard-
son.

played to print the Journals of the House of Commons, in twenty-six volumes folio. In 1754 he was chosen master of the Stationers' Company. In 1760 he purchased a moiety of the patent of law-printer to his Majesty, and in this branch of his business he was joint partner with Miss Catherine Lintot. He was thus enabled to live in comfort, and to make a suitable provision for his family. Like other prosperous citizens he set a due value on country air, and had first a residence at North End near Hammersmith, and afterwards at Parsons Green near Fulham, where he spent such intervals of time as he could spare from business, and where he was seldom without visitors.

The first work that recommended him to public notice was *Pamela, or Virtue Rewarded*, published in the year 1741. The two volumes of which it originally consisted appear to have been written in less than three months. Its success was almost unprecedented, for it reached a fifth edition within the space of a year. "The printer in Salisbury Court," says Mrs Barbauld, "was to create a new species of writing; his name was to be familiar in the mouths of the great, the witty, and the gay, and he was destined to give one motive more to the rest of Europe to learn the language of his country." Some inconsistencies in the work were powerfully ridiculed by Fielding in his *History of Joseph Andrews*, whom he introduces to his readers as the brother of Pamela. This was an injury which Richardson, though an amiable and benevolent man, found it very difficult, if not impossible, to forgive. In his correspondence with his admiring friends he predicted that Fielding would speedily sink into oblivion. But, in the present age, for every reader of *Pamela* and *Clarissa* there are at least five hundred of *Joseph Andrews* and *Tom Jones*.

The brilliant success of this novel prompted some nameless individual to write and publish a continuation of the story, under the title of *Pamela in High Life*. Richardson, who might very safely have disregarded such an attempt to invade his province, was thus induced to add a second part, which however made no addition to his reputation. "These volumes," says Mrs Barbauld, "two in number, are, like most second parts, greatly inferior to the first. They are superfluous, for the plan was already completed; and they are dull, for instead of incident and passion, they are filled with heavy sentiment, in diction far from elegant. A great part of it aims to palliate, by counter-criticism, the faults which had been found in the first parts. It is less a continuation than the author's defence of himself." On the story of Pamela the famous dramatist Goldoni has written two of his plays, *Pamela Nubile* and *Pamela Maritata*.

In the year 1749, Richardson published the first two volumes of *The History of Clarissa Harlowe*. This work, which he extended to eight volumes, is the chief foundation of his celebrity as an original and inventive writer. Notwithstanding its inordinate length, the book long continued to enjoy an almost unrivalled share of public favour, and, whatever may be its defects or redundancies, this favour could only be secured by the author's power over the imagination and moral feelings. The outline of the story is sufficiently simple, nor is the curiosity of the reader excited by intricate plots and marvellous adventures. It is a work, not of action and enterprise, but of character and sentiment. His next production was *The History of Sir Charles Grandison*, published in 1753, in seven volumes. In his previous works he had given ample delineations of female character, and he now endeavoured to exhibit a pattern of a perfect man. Whatever is graceful and engaging in the man of spirit and fine gentleman it was his aim to unite with every moral virtue, and with the strict observance of Christian principles. This was certainly a difficult enterprise; and the writer's genius is more successfully displayed in delineating the character of Clementina, than in portraying

ing that of his hero. The nervous system of Richardson was naturally weak; and during his latter years his hand shook, and he was subject to frequent fits of giddiness. His disorders having at length terminated in apoplexy, he died on the 4th of July 1761, at the age of seventy-two.

Richardson left behind him the character of a virtuous and benevolent man, highly respected in all the relations of private life. His chief weakness seems to have been vanity, which is sufficiently displayed in his private correspondence. His success in literature was so great and so unexpected, and he received so much flattery from his friends, especially from his female friends, that it would have required a very firm texture of mind to resist the access of that passion which so easily converts a wise man into a fool. He was twice married. His first wife was Miss Allington Wilde, daughter of the printer with whom he served his apprenticeship. She bore him five sons and a daughter, who all died young. His second wife, who survived him for many years, was Elizabeth, the sister of Mr Leake, a bookseller of Bath. She became the mother of a son and five daughters. The son died at an early age, but four of the daughters survived him: Mary, married in 1757 to Mr Ditcher, an eminent surgeon of Bath; Martha, married in 1762 to Edward Bridgen, Esq.; Anne, who died unmarried in 1804; and Sarah, married to Mr Crowther, surgeon of Boswell Court.

Besides his three novels in nineteen volumes, he published some other works. *The Negotiations of Sir Thomas Roe, in his Embassy to the Ottoman Porte from 1621 to 1628 inclusive*, 1740, fol.; *An edition of Æsop's Fables, with Reflections; Familiar Letters to and from several Persons upon Business and other subjects*. He furnished some additions to the sixth edition of De Foe's *Tour through Great Britain*; and some of his contributions are to be found in periodical works. Long after his death appeared *The Correspondence of Samuel Richardson, author of Pamela, Clarissa, and Sir Charles Grandison; selected from the original manuscripts bequeathed by him to his family; to which are prefixed a Biographical Account of that Author, and Observations on his Writings*, by Anna Lætitia Barbauld, London, 1804, 6 vols. 12mo. His works, with a sketch of his life and writings, by the Rev. Ed. Mangin, appeared in 19 vols., London, 1811. (For an estimate of Richardson's place as a novelist, see ROMANCE.)

RICHELIEU, ARMAND JEAN DUPLESSIS, Cardinal, *Duc de*, was the younger son of a Poitiers gentleman, whose impoverished exchequer did not allow him to support, in anything like style, the honours of his genealogical tree. Born on the 5th of September 1585, he received a tolerable education preparatory to his entering the army. One of his brothers, Alphonse, had already been comfortably provided for by the church, and a bishop's mitre at Luçon was the first prize which the Poitiers *gentilhomme* secured towards the worldly welfare of his family. Whilst the prelate thus sailed easily down the stream of life, the soldier would have to fight his way to distinction sword in hand, starting with the usual chances of a *cadet de famille*. History does not inform us whether young Armand's inclination was in accordance with the parental will; but certainly his subsequent conduct at the siege of La Rochelle proves that he was more at home on the field of battle than in the arena of theological discussion. The Bishop of Luçon had not yet been consecrated when, under the impression of religious scruples, he was induced to renounce a position so many would have earnestly coveted, and to withdraw himself entirely from the world. He entered a Carthusian monastery. This circumstance was likely to prove a serious matter to the straitened fortunes of the Duplessis family; but our soldier *in posse* thought that he was called upon to retain at any cost the position his brother had parted with; so, throwing back his sword into the scabbard, he adopted

Richelieu.

Richelieu.

the crozier as the prop of his rising destinies. None of the transactions connected with this episcopal promotion will bear close examination. Richelieu was only twenty years old when it took place, and a great many difficulties were raised by the Pope, not without strong reasons. Henri IV. had to interfere; the French ambassador at Rome exhausted all his diplomatic resources; as a final climax, Richelieu himself started for the Eternal City, fully determined to conquer. His Holiness yielded at last, and the ceremony of consecration took place on April 17, 1608. The young Bishop of Luçon immediately after repaired to his diocese. Arriving in a part of France where the majority of the people belonged to the Protestant religion, Richelieu resolved to discharge his duties with vigour and prudence. He would settle differences, soften irritations, and display uniformly the spirit of forbearance, when brought into contact with his Huguenot diocesans. "Gentlemen," he said, in a sort of oratorical programme to that effect, "as I am come to live with you, and to make my habitual abode in this place, there is nothing that can be more agreeable to me than to see your faces, and to know from your own declarations that you feel pleasure at my presence. I thank you for the good wishes you express. I shall do my best to deserve them by every kindness in my power; for the strongest anxiety I have is, that I may be useful to all and each of you. There are some in this company who are separated from us, as I am aware, on matters of faith; may we, notwithstanding, be all united together in the bond of charity! I shall do all I can towards that object; it will be as useful to them as to us, besides pleasing the king, whom every one of us is bound to obey. Time will prove more fully than anything I can say the affection I bear to you; I shall therefore leave deeds to show that your welfare will be the end of my endeavours."¹

If Richelieu manifested kindly dispositions towards the Huguenot separatists, he affected likewise a strong sympathy for the common people, who, overwhelmed by taxes, and bearing the dreadful consequences of a protracted succession of civil wars, could hardly eke out a miserable livelihood. He solicited and obtained for them some slight relief. Here, however, we discover a strong contrast in the principles which the despotic statesman adopted subsequently as the foundation of all true government. "All politicians," he wrote, in his celebrated *Testament Politique*, "are agreed that, if the people's circumstances were too easy, it would be impossible to keep them within the bounds of duty. We must compare them to mules, which, being accustomed to burdens, are more injured by repose than by work."

What with the Huguenots, and what with the lame condition to which "the mules" were reduced, the see of Luçon does not appear to have been a very lucrative benefice. Richelieu, the powerful genius who ruled so long over the destinies of France, and whose very name struck terror into the heart of Austria,—Richelieu began by driving bargains for some cheap church furniture, and doing duty in second-best surplices. A number of letters written by him at this period have been published; they are full of little chit-chat on domestic grievances,—letters which show that the bishop then lived in a laudable state of apostolic simplicity. His favourite correspondent was a Madame de Bourges, who resided in Paris, and who seems to have been in the habit of procuring for the young prelate the necessities he required from time to time. "I shall find no lack of occupation here," he writes to her in April 1609, "I assure you; everything is in such a ruinous condition that it will require hard labour to set matters right again. I am very badly off for lodgings, as there is not one chimney but

smokes. You may imagine that I am not anxious for a severe winter: patience, however, is the best remedy. I can give you my word that my bishopric is the ugliest, the muddiest, the most disagreeable in the kingdom; but I leave you to guess what is the condition of the bishop. I have neither garden nor avenue, nor any place at all where I may take a walk; I am, in fact, a prisoner in my own house. I break off this discourse to tell you that we could not find amongst my clothes a tunic and a dalmatica of white taffeta, which were to be forwarded with the white damask ornaments you ordered for me; this makes me think that they must have been forgotten."

Many of the letters to Madame de Bourges are exactly in the same style; trifling topics are discussed, sometimes in a genuine vein of comic humour, always with a kind of philosophic *insouciance*. Then our bishop, after having sedulously done what he could amidst the Huguenots and the "mules" of the diocese, feels that he ought to refresh himself by a journey to Paris, and a visit to those who, at the Louvre, dispense honours, riches, and power. There is the Bishop of Evreux, Du Perron; his controversial works have procured him almost the reputation of an oracle; his sermons are drawing large crowds to Notre Dame; he has become a *lionized* prelate, and a man of unbounded influence. "Why," quoth Richelieu, "should not I walk in his footsteps?" But in order to do so he must have an hôtel in Paris. An hôtel! Yes, for the sake of decorum—of appearances. For a bishop, furnished lodgings would hardly be the thing. Madame de Bourges, that excellent housekeeper, is once more consulted. "You will oblige me much by your good advice: I am rather hesitating, especially about a house. On one hand, I am afraid that much furniture will be required; on the other, as my temper, similar to yours, is a little inclined towards vainglory, I should like both to be more comfortable, and also to make some figure. Now this might be more conveniently managed if I had a house of my own. A poor nobleman is a pitiable thing; yet there is no helping that."

And accordingly, off to Paris he went, determined to make his way at court, and to get into some sort of notice. His first attempt proved a signal failure; he endeavoured to create a sensation by his sermons, and preached several times before the queen, but apparently to no purpose. Nay, if we believe Priolo, the Bishop of Luçon was *infelix concionator*. Altogether, the result of these Paris journeys does not seem to have been very encouraging. Richelieu returned to his diocese, and soon found out that, without taking the trouble of a long and expensive pilgrimage from Poitou to the metropolis, he could have secured close at hand, the advice, the encouragement, and the assistance which he required.

There lived at that time in the west of France a man whose religious zeal and whose talent as a preacher were much talked of. François Leclerc du Tremblay, a Capuchian friar, better known afterwards as *Father Joseph*, had, when twenty-two years old, renounced the most brilliant prospects to embrace the monastic life. Neither the earnest entreaties of his mother nor the allurements of the world could avail. He donned the cowl; but by his transcendent powers soon raised himself to the highest posts in his community. He uncompromisingly denounced from the pulpit the lax ideas which the civil wars had introduced into the church, and which especially infected the convents. Moved by his sermons, the nuns of Fontevault had even requested him to draw up a plan for the reformation of the monasteries belonging to their order. This Father Joseph did successfully; but in order to consolidate the work he had been enabled to begin, he wished to secure the appointment, as

Richelieu.

¹ See for all this the first volume of Richelieu's correspondence, published by M. Avenel, and the clever articles of M. Sainte-Bouve in the *Causeries du Lundi*, vol. vii.

Richelieu, abbess, of Antoinette d'Orléans, sister of the Duc de Longueville; and some difficulties, it would seem, stood in the way of this nomination. The Bishop of Luçon was then residing in the Priory des Roches, near Fontevault; Father Joseph called upon him for his advice. These two clever men soon understood each other's character; and although Du Tremblay was eight years older than Richelieu, he constantly affected to receive his instructions with the greatest respect. When they both went to court for the purpose of reporting about the settlement of the Fontevault business, Father Joseph spoke of Richelieu to Marie de Medici as of a superior prelate who could render her the greatest services.

We have seen the bishop endeavouring to steer his course steadily amongst difficulties of a temporal nature. He was not by any means so fortunate in disposing of cases connected with the anxieties of the soul and the appeals of conscience. He was ignorant of spiritual things; and the few letters reprinted that relate to such subjects are as commonplace and tame as can be imagined. Fancy his reverence sitting down to his desk with a *Complete Religious Letter-Writer* before him, and instead of giving to the distressed the outpourings of his heart, sending to them pages from a manual published *cum privilegio*. If we would study the veritable Richelieu, and see him himself again, we must turn to the despatches in which he lectures a vicar-general or a parish priest. Let the following (penned in 1610) suffice by way of specimen:—"Sir, I have received the letter you wrote to me on the subject of the differences which have arisen between M. De la Coussaye and yourself. I cannot but blame you for them, because my desire is, that those who have the management of affairs in my diocese should live in peace together. I inform M. De la Coussaye of this, and I warn you likewise, so that you may make it your object to preserve union. You are both my vicars-general, and as such your only aim ought to be to please me in all things, which will certainly be the case, provided you act for the glory of God. Your letter makes it clear that you were out of temper when you took up your pen; for my part, I love my friends so well that I wish to be acquainted only with their good tempers, and in my opinion they ought not to show any other. . . . Thank God, I know how to behave myself, and I know still better how they should behave who are placed under me. . . . I wish you to tell me of the irregularities which you may notice in my diocese; but you must do so more gently."

The circumstances in which Richelieu was placed at that time compelled him to display much deference to some people respecting whom he entertained in after-life a very different opinion. For instance, while he is only the insignificant Bishop of Luçon, wearing questionable surplices, and dwelling in a house with smoky chimneys, he can write to Sully in the most submissive manner. A letter, dated September 21, 1612, begins thus:—"Sir, if I had as many ways of being of service to you as I have occasion to be importunate, I would prove my affection and my zeal with as much pleasure as I feel pain now, in taking up the pen to beg for undeserved marks of your benevolence. I would never have ventured to do so had I not been aware that those who may be called truly great, more by their qualities than by the offices they fill, are very glad of an opportunity of assisting their inferiors; for they prove thus, that if their power commends them, their kindness places them higher still," &c. &c. Compare the obsequious tone which characterises the above letter with the opinions which the prelate gives of Sully in the *Histoire de la Mère et du Fils*. We should, however, remember that, as late as 1626, contemporary historians and annalists took very little notice of Richelieu. When they speak of him, it is quite *par hasard*, and often in the most disparaging manner. Baptiste Le Grain's allusion to the bishop is not only laconic, but bor-

dering upon contempt. Savaron, relating the opening of the States-General in 1614, merely says that Richelieu, in delivering up the *cahiers* of the clergy, spoke for a long hour. Then, when he describes the negotiations which took place between the king and the queen-mother,—negotiations in which Richelieu played so conspicuous a part,—he omits his name altogether, alluding only to Cardinal de la Rochefoucauld and to Father de Bérulle. Paul Phélypeaux de Pontchartrain, who had been employed since 1610 as secretary of state in the most important transactions, and who must have been well acquainted with Richelieu, has the following sentence, under the date of December 1616:—"About that time several rumours were spread abroad. . . . All the old ministers were to withdraw and to make way for two or three men whose sole merit and experience consisted in their abetting the designs of the marshal (Concini), and of his wife." Appreciations such as these are scarcely credible, except upon the supposition, that the writers who penned them were blinded either by party spirit or by jealousy.

The murder of Henri II. produced in Europe the effect of a thunderbolt. At the time when that event was permitted to happen, France had reached a state of prosperity which seemed doubly glorious after the horrors of the civil wars. Party animosity was gradually subsiding, and Catholics and Protestants were living together in the bonds of mutual forbearance. But, on the other hand, it must be acknowledged that the Edict of Nantes was grounded upon a wrong basis; the Protestants were considered, not as a church, but as a political community; whilst the edict was odious to the crown, it could hardly satisfy the Huguenots; and it was quite evident that, as soon as the stroke of death removed the monarch who had brought about the compact, the structure he had reared would speedily fall to the ground. The persons most anxious to play a part in the game of politics observed each other closely; and Richelieu's absence from his diocese became a matter of common occurrence. We have already alluded to the speech which he pronounced before the States-General. It is a tedious composition, written in the affected style of the age, and rather remarkable for the view the orator takes of administration and public business. He succeeded so thoroughly in flattering the ambition of Marie de Medici that she named him almoner to her household,—a post which, by-the-bye, he did not long retain, for a few days only after his appointment he sold it, *permissione superiorum*, to the Bishop of Langres. This was, we must acknowledge, a smart way of raising the wind, and of proving that our *pauvre noblesse* had their wits about them. With the results of the bargain Richelieu could keep up a better establishment than the one which Madame de Bourges enabled him to maintain; and he patiently awaited the course of events. In the meanwhile, he was very assiduous in his attentions to the powers that were,—the under-secretary of state Barbin, Concini, and Leonora Galigai. The storm of factions was agitating the court; amidst a crowd of petty intriguers and of men whose talents were not equal to their ambition, Concini felt the advantage of securing the cool judgment and the steady determination of Richelieu.

And truly France had been reduced to a pitiable condition. From the height of prosperity it had sunk into the most precarious state. Indolent, headstrong, and wavering, the queen-mother, Marie de Medici, retained for her advisers the men least capable of offering her a firm support in the season of adversity. Villeroy, Jeannin, Sillery, possessed ability no doubt, but only as instruments in the master's hands. They could not take the initiative: guide them, they would act judiciously; leave them to themselves, and they were lost. The nobles, who still entertained the hope of regaining their former power, had at first reckoned upon the support of the States-General. De-

Richelieu.

ceived in this expectation, they had withdrawn altogether from the court, and, strengthened by crowds of adventurers still anxious for plunder and thirsting for blood, they raised the standard of civil war. Such was the general desolation that the king had an army to attend his progress when he went to Bordeaux, on the occasion of his own marriage with Ann of Austria, and to settle the union between his sister Elizabeth and the son of Philip III. In the interim, Father Joseph had undertaken to negotiate with the confederate princes who were then assembled at Saint Maixent; in the name of the queen-mother, Marshal Brissac and the Duc de Villeroy began a series of conferences which the ambition of the rebels protracted as much as possible. At length, in the first days of May 1616, a peace was signed at Loudun, the terms of which implied so much weakness on the part of the government that, although the princes had obtained every pledge they required, it was evident they did not intend to be satisfied at so cheap a rate. "The princes," says Richelieu in his memoirs, "received from the king great gifts and rewards instead of the punishment they deserved; consequently they did not abandon to his Majesty the faith they had sold him so dear; or, if they did, it was not for long." In fact, the pretensions of the nobles rose as high as the throne: they talked of nothing less than shutting up the queen in a convent, and giving the crown to the Prince de Condé. The danger became imminent; France had an aftertaste of the League, or an anticipation of the Fronde. Things demanded an act of vigour and determination. Whilst Villeroy, Jeannin, and Sillery were hesitating, and forming a thousand resolutions which they did not know how to carry out, Richelieu, Barbin, and a few others prevailed upon the queen to sanction the arrest of the princes. She did so; but the plan was so clumsily managed that Condé alone was secured. It is not at all unlikely that the escape of the rest, which a little would have prevented, hastened the advent of Richelieu to the ministry. He had himself vainly attempted to negotiate with the Duc de Nevers; hostilities were already beginning in several places, and a civil war was opening of which no one could foresee the result. On November 30, 1616, Armand Jean du Plessis de Richelieu received his commission as secretary of state, with the right of precedence over all his colleagues. He had already for some time been employed upon missions of no slight moment, and he had even been appointed to proceed to Spain in the capacity of an ambassador. This was a post he would much like to have filled; but the fresh propositions which the queen made to him through Concini were still more to his taste, and he accordingly took his seat at the council-board as the leader of a few obscure but zealous men. It was a ministry inspired by the most vigorous patriotism. One obstacle, however, stood in the way of their usefulness,—they had met, so to speak, under the patronage of Marshal d'Ancre, and this circumstance rendered them unpopular.

Richelieu had not long assumed the presidency of the new cabinet when a strange revolution took place in the management of public affairs; it became evident that an experienced hand was at the helm, and that decision and firmness were to be the principles that should prevail. An impartial historian must conceal none of the difficulties which Richelieu had to surmount during this his first ministry. In the first place, although he was nominally the *premier*, yet his influence was not, by any means, unchecked. The under-secretary Barbin, for instance, had almost equal power; and it was clear that a man of less energy than Richelieu could not have kept the cabinet together for a month. The want of money proved a more serious obstacle; the exchequer was empty, and Richelieu had often to advance funds in order to defray the necessary expenses which occurred in the course of business.

Richelieu.

The armies were badly equipped, badly paid, and either utterly dispirited, or in a complete state of insubordination. There were, besides, no sources of information that could be relied upon; not one single document or copy of a despatch existed at the seat of government; state-papers had never been deemed worth preservation; and the ministers were absolutely compelled to labour in the dark. But difficulties are the test of genius; and Richelieu overcame all those which stood in his way. He began by inviting, in the most energetic manner, the princes and the other rebel leaders to return to their duty; taking, at the same time, all the necessary means of compelling them to do so. Whilst fresh levies were being raised, and the army remodelled, ambassadors were despatched to England, to Germany, to the Netherlands, for the purpose of depriving the rebels of the assistance they expected from those foreign courts. Richelieu's request, however, did not determine the princes to lay down their arms. Consequently all things being now ready, a warrant of high treason was issued against them: three different armies took the field, and attacked them simultaneously in Champagne, Berry, and L'Ile de France. In the course of two months the princes, completely beaten, and driven from the posts which they occupied, were obliged to surrender unconditionally in the hands of the king.

When the *coup d'état* of April 24, 1617, in bringing De Luynes to power, revived once more, but for a short time only, the expectations of the nobility, Richelieu, by an exceptional piece of good luck, did not suffer for his devotedness to the queen-mother. Probably his position as an ecclesiastic secured to him some measure of respect; but this was not all. He had managed to gain by timely flattery the good-will of the new favourite, and the very alteration which took place in his fortunes only brought him more prominently forward. Banished as he was at Mirebeau, he contrived to interest both parties on his behalf. To the court he adduced his withdrawal from public business as a proof of the most absolute submission; to Marie de Medici he described it as the result of his unremitting zeal for her service, and as a new persecution on the part of her enemies. He thus contrived to weather the storm; and when the excitement produced by the catastrophe of Concini had subsided, he looked round to see what could be done. We cannot enter here into the particulars connected with the disgrace of the queen-mother. Suffice it to say, that Richelieu served her to the utmost of his power, and rendered her party so formidable that it proved a serious obstacle to the ambitious views of the new favourite. The Bishop of Luçon through his intrigues, his determination, and his unscrupulous conduct, had become a dangerous personage; he was first ordered to return to his priory at Coussay, then to his episcopal palace, and finally he was banished to Avignon. There he seemed determined upon leading a life of retirement; and a casual observer, anxious to know how he spent his time, would have found him busily employed in writing theological works. This, of course, was merely a feint, designed to throw his enemies off their guard. Attention to his books did not prevent Richelieu from observing the course of events; and when Marie de Medici contrived to escape from Blois, he joined her without any further delay. By his influence, the whole of the Anjou nobility—the Ducs de Longueville, de Bouillon, d'Epemon—rallied round the standard of the queen. The issue of this campaign is well known. A battle was fought at Pont de Cé, near Angers, where the rebel troops met with a signal defeat. A treaty, nevertheless, concluded shortly after, secured to Richelieu almost as many advantages as if he and not De Luynes had triumphed. The queen received permission to return to court, with the full enjoyment of all the privileges and honours due to her rank; and the king pledged himself to

Richelieu. solicit a cardinal's hat for Richelieu, whose niece, Made-moiselle de Pont Courlay, married the Marquis de Combalet, nephew of De Luynes.

After the death of the favourite in 1621, Richelieu did not immediately return to power, but he saw that his day was coming; and when he resumed again the supreme authority, his reign lasted without interruption till the fatal moment which saw him struck down, as it were, at the foot of the scaffold to which he had sent Cinq-Mars and De Thou. Louis XIII. had always, from the very first, felt an unconquerable aversion for the Bishop of Luçon, and it was with the greatest difficulty that Marie de Medici obtained the prelate's appointment to the office of privy-councillor. The patent was signed nevertheless, and although no definite duties were assigned to him, it was not long before he cast all his colleagues into the shade. The first important result accomplished by the new ministry was the marriage of Henrietta, the beautiful daughter of the late king, with the Prince of Wales. This match had already been contemplated by La Vieuville under the Luynes administration. It was an object of the highest moment, as it strengthened France against the influence of Austria;—Austria, the Carthage of Richelieu—the enemy which he must destroy at any cost. The Pope, reduced at that time to act as a mere tool in the hands of the Spaniards, was occupying on their behalf the Valteline, and thus protecting their communication with the German empire through the passes of the Alps. Instead of gaining the neutrality of Switzerland by a series of negotiations which would have wasted time, Richelieu sends (1624) the Marquis de Cœuvres against the Papal troops, at the head of a Swiss army, and we witness the singular spectacle of a Roman Catholic prelate defeating the successor of St Peter with weapons both spiritual and temporal;—we say spiritual, because Richelieu had obtained from the theological board at the Sorbonne a sort of salvo for his conscience. Many have professed astonishment at the system of policy thus adopted by the French minister. It has seemed inconsistent for a cardinal to start in his ministerial career by making an alliance with two heretic nations, England and the Netherlands, and by waging war against the Pope; but we must not forget that the preservation of France, as a first-rate political power, was the great end the cardinal had in view: to this he sacrificed every other consideration, and, without any scruple respecting the means employed, pushed forward to the goal. He once said to La Vieuville,—"I never undertake anything without having well considered it; but when I have made up my mind I go on resolutely, overthrowing every obstacle, mowing down every impediment, and then I cover everything under my red gown." To form an accurate idea of the system of policy pursued by Richelieu, it is only necessary to read Gabriel Naude's *Apologie pour les Coups d'Etat*. It is there explained in a few pages; and the despotic cardinal might, if he had thought fit, have produced from that volume, chapter and verse to justify the decapitation of Marillac and the death of Puylaurens.

The following year the energetic minister made a trial of his strength upon the Huguenots, but at that period France had no navy, and the Protestants of La Rochelle, supported by the English government, would have easily triumphed over the troops of Louis XIII. if an attack had been directed against that well-fortified town. The Bishop of Luçon determined to wait for a while; and, notwithstanding all the squibs and pasquils which were levelled at him, he treated with the Protestant party. This short delay was employed by him in necessary preparations, and in securing the means of effective action afterwards. He began by obtaining from Montmorency the cession of the admiralship; he suppressed the important post of constable, and all the other high offices connected with the crown; an

assembly of the notables, called together under Richelieu's own influence, voted considerable reductions in the salaries of the state dignitaries; the fortresses not situated on the frontiers were completely destroyed. These summary reforms evidently were chiefly designed to reduce the power of the nobles. For the achievement of this object, Richelieu spared neither time nor means. The mania of duelling during the seventeenth century had reached so extraordinary a pitch that, in the course of twenty years, 8000 letters of free pardon were signed by the king on behalf of *gentilshommes* who had either sent or received challenges. This barbarous custom was stopped at once. Comte de Chapelle and the Duc de Bouville had fought a duel on the Place Royale in Paris; they were both beheaded. John Barclay, in the complimentary epistle to Louis XIII., which forms the Preface of his *Argenis*, says:—"Nec acrior sceptri vindex fuisti, quam deinde salutis singulorum: impio more sublato, qui jubebat Gallos tuos, levibus inter se rixis commissis, passim jugulum suum dare, aut petere alienum." Richelieu has a claim to the full benefit of this congratulation; but we cannot believe that humanity was the chief motive which actuated him in his legislative enactments against duelling. He took advantage of what had become a fashionable mania to deal a blow at the nobility, who, he well knew, would quarrel and challenge one another in spite of the strictest edicts.

It was not to be expected that the cardinal would meet with no opposition in the course of his administration. A conspiracy, excited by the Duchess de Chevreuse and some other ladies (the fair sex have always been politicians in France), was organized in support of Gaston, Duke of Orleans. They wanted that indolent prince to wrest from Richelieu's iron hand a sceptre which no one else could safely wield; they had even gone so far as to arrange for him a matrimonial alliance with a foreign princess. The minister lost not a minute; but first he would try what gentle means might do; and he presented D'Ornano, Gaston's governor, with the *bâton* of a marshal of France. This act of kindness was mistaken for fear, and the conspirators became bolder than ever: then a perfect *razzia* took place; every legal form was preserved by prosecutors who were entirely and unreservedly devoted to Richelieu. Chalais, the ringleader, forfeited his life; Gaston in the meanwhile quietly got out of the way, purchased his own safety by the most abject apologies, and whilst the executioner was busy with his friends, he married Marie de Bourbon. D'Ornano died (poisoned 1626) within the walls of the Bastille.

The terrible manner in which Richelieu treated the turbulent remains of feudalism produced for a short time the desired effect; and, free from every other obstacle, he could now devote his whole attention to his favourite scheme, the destruction of the Protestants as a *political party* in France. The greatest mistake Henri IV. ever committed was the introduction in the Edict of Nantes of the clauses which preserved the status of the Huguenots as a political body. If we examine their condition at the beginning of the reign of Louis XIII., we see that they formed an *imperium in imperio*, and ambitious men knew well what use to make of this element of strife. Not only did they possess their places of safety, their assemblies, and their military leaders, but the Duc de Rohan entertained the hope of organizing in France a Calvinist republic on the model offered by the united provinces of Holland. The confusion of the temporal and the spiritual principles in matters of government has ever been productive of the greatest mischief; and it seems clear that, if the French Protestants had not yielded to the perfidious solicitations of Rohan and Lesdiguières,—if they had been satisfied with the enjoyment of religious liberty,—they would not, at all

Richelieu.

Richelieu. events, have supplied their adversaries with a pretext to begin the work of destruction which the ill-advised Louis XIV. carried out. An apology for commencing the war was not long wanting. The Duke of Buckingham, who had been foolish and impudent enough to boast openly of being the favoured lover of Anne of Austria, was informed that if he attempted to land in France, orders were issued for his immediate arrest. Highly irritated at this insult, he determined to be revenged; and, at the Duc de Rohan's request, he sailed with a few thousand men to support the Protestant Rochellese in another civil war. Such an expedition might have been crowned with success if the English government had persevered in countenancing the Huguenots; but Charles I. found sufficient work to occupy him at home without interfering with foreign politics; and, despite the most obstinate resistance, the citizens of La Rochelle, left to their own resources, were compelled (1628) to surrender. The war continued for a short time in the south of France; but at last the Duc de Rohan, one of the chief Protestant leaders, laid down his arms: his submission, which brought about that of the whole party, was purchased at the price of a hundred thousand crowns. The taking of La Rochelle may be considered as one of the most important events in the history of Richelieu; it was a fatal blow, not only to the political strength of the Huguenots, but also to the ambition of the nobles. One of those chieftains who accompanied the royal army had said, "We shall not be such fools as to take La Rochelle;" and in expressing himself thus, he gave utterance to the feelings of the whole party; for they had in the capital of French Protestantism a powerful auxiliary with whom they combined when they wanted to annoy the government by the threat of a civil war. La Rochelle surrendered, however; and the best proof that all this transaction was a political, not a religious one, is to be seen in the terms imposed by Richelieu. They were hard, no doubt; but they included neither the demolition of the Protestant churches, nor any infringement of the rights of public worship. We may say, in short, that under the administration of Richelieu, and of his successor Mazarin, the French Protestants were in a very favourable condition.

Richelieu's policy was developed with such energy that success crowned all his endeavours. As to the means employed he never felt very scrupulous; and his subordinates, with the exception of Father Joseph Chavigny, and a few others, were undoubtedly the greatest ruffians of their time. What an interesting sight for any one who could have been admitted for a moment within the walls of that council-chamber when the *cadet* of the House of Richelieu, now a cardinal, a peer of the realm, and the true king of France, was preparing from his arm-chair by the fireside the unity of the state and the glory of Louis XIV. To see the *éminence rouge* discussing with Father Joseph—the *éminence grise*—a plan of attack against John de Wert, or the execution of some impudent young nobleman, compromised in a new freak of the Duke of Orleans. Above the door of that chamber might have been written, by way of a motto, the aphorism which Gabriel Naudé himself proposes: *Salus populi suprema lex esto*. But let us notice that Robespierre, Danton, and the terrorists of '93, adopted no other motto. There is a point when red republicans and red-cassocked despots meet, both borrowing their statecraft from the atrocious recipes supplied by the *Apologie pour les Coups d'Etat*.

The Protestants being now subdued at home, Richelieu defeated the Catholics abroad: penetrating into Italy, he secured to the Duke de Nevers the possession of Mantua and of the Montferrate (1630), and destroyed for ever the Spanish influence in a peninsula where that nation had enjoyed an absolute sway since the days of Charles V.

Richelieu. The events of the war had brought the court to the south of France. Anne of Austria, Marie de Medici, all the ministers, were there, accompanied by a suite of noblemen, who, not frightened at the fate of D'Ornano and Chalais, were again watching a favourable opportunity to effect the disgrace of Richelieu. These reiterated attempts are surprising enough; but what astonishes us most is, that the conspirators should have allowed themselves to be led astray by Gaston, Duc d'Orleans,—a man who, in the hour of danger, would not hesitate to betray his bosom friend, if his own safety could be purchased at such a price. And yet they fell into the snare. The king was dangerously ill at Lyons; they thought the opportunity too good to be lost; and indeed managed so well, that when the court had returned to Paris, the cardinal's disgrace seemed inevitable. But he determined upon making a final effort; and, securing an interview of a quarter of an hour with Louis XIII. at Versailles, he frightened the monarch, and left the palace as powerful as ever. "This *coup d'état*," says M. Michelet (*Précis d'Histoire Moderne*), "was a perfect comedy: the cardinalists packed off in the morning, and it was the turn of the royalists to make their exit at sunset. Marshal Marillac had to pay for the rest; seized in the middle of his army, he was tried before a court composed of his private enemies, and in the cardinal's very palace at Ruel. Of course, under such circumstances, it was useless to expect mercy: the unfortunate warrior was beheaded. In the meanwhile, what had become of Gaston? Banished with his mother to Brussels, he felt at last some shame at not taking any personal part in the struggle against his enemy. Besides, the Duc de Montmorency, governor of Languedoc, had informed him that his presence in the disaffected provinces would undoubtedly excite a general rebellion. Assisted by the Duc de Lorraine, whose daughter he had married, Gaston raised an army of brigands, as they have justly been termed. Unfortunately, in order to reach Languedoc, it was necessary that this select band should cross France from north to south. Badly paid, badly fed, they took to pillage by way of compensation, and thus materially impaired the cause they were engaged to serve. A battle was fought (1632) at Castelnaudary; the king's troops were victorious, and Montmorency shared the fate of Marillac, whilst Gaston d'Orleans, "swore by the faith of a gentleman that he would ever be my lord the cardinal's best friend."

The destruction of the House of Austria was the great object of Richelieu's foreign diplomacy. The Thirty Years' War, now raging in all its fury, had increased an hundred-fold the emperor's power. Tilly, Wallenstein, Bernard of Saxe-Weimar—Schiller's heroes—were upholding, sword in hand, on many battle-fields, the destinies of the House of Austria. Richelieu's genius and activity checked the valour of the great imperialist generals, and opposed to them a warrior who, in his short career, abundantly proved that a clever system of tactics does not always ensure success. Gustavus Adolphus, the hero of Lutzen, fought at the same time the battles of Richelieu and those of the Protestant cause. After the death of the King of Sweden, the position of France became for awhile extremely difficult. The imperialists assumed the offensive; they had entered France by Burgundy and by Picardy. If Bernard of Saxe-Weimar had not gained the two battles of Rheinfeld and Brissach, it is impossible to conjecture what would have been the issue. In the year 1640, however, Richelieu adopted a more expeditious plan: he occupied the Spaniards at home by sending his support to the rebels of Catalonia and of Portugal; whilst, to retaliate, the government of Madrid espoused the Duke of Orleans' cause, and prepared the catastrophe which was to impart such a tragic feature to the last moments of the great cardinal. M.

Richelieu. Alfred de Vigny's admirable romance¹ has thrown over the insignificant figure of Cinq Mars a lustre which it certainly does not deserve; but the history of this mad-cap conspiracy, whilst it proves to us the cold and selfish character of Louis XIII., is an instructive lecture on the folly of those who trust to the smiles of kings and princes. Richelieu lived long enough to see the French standard hoisted on the walls of Perpignan, and when death at last summoned him away, in the year 1642, he left a successor, Giulio Mazarini, who was one day to complete with almost greater skill than his patron the work begun by Armand Jean du Plessis. In estimating the government of Cardinal Richelieu,² it must be admitted that the unity of France was worth purchasing at the expense of some measures of extraordinary severity; but it is equally true that Richelieu's motto was essentially the lust of domination, and whatever may have been the results of his administration, the only object he had set his heart upon was to reign without a rival. We should also observe, as the key-stone of the cardinal's home-policy, the establishment of that scheme of absolute monarchy which, ever since the days of Philippe-le-bel, has been gradually developing itself in France. By the ruin of the aristocracy and the insignificant position to which the Parliament were reduced, the balance of power was completely destroyed; and the nation, thus deprived of all legitimate means of making known its wishes, its grievances, and its sympathies, became alienated from rulers who, in the course of time, had not even the merit of energy and enlightened patriotism to justify the abuse of authority. Another important fact, which we have already had occasion to notice, is the reform introduced by Richelieu in the various branches of the service. Here he certainly manifested great discernment, and made for the good of the country sacrifices which cannot be thought lightly of. The following passage from the *Testament Politique* will be enough to illustrate this fact:—"Je supplie aussi très humblement sa Majesté de trouver bon que l'on lui mette entre les mains la somme de 1,500,000 livres, de laquelle je puis dire avec vérité m'être servi très utilement aux grandes affaires de sa Etat, en sorte que si je n'eusse eu cet argent à ma disposition, quelques affaires qui ont bien succédé eussent apparemment mal réussi, ce qui me donne sujet d'oser supplier sa Majesté de destiner cette somme que je lui laisse pour employer en diverses circonstances qui ne peuvent souffrir la longueur des formes de finances."

It will scarcely be credited that Cardinal de Richelieu, amidst all the requirements of politics, found time to cultivate literature. History informs us that Bonaparte was prouder of belonging to the Institute than of wearing the epaulettes of general-in-chief; from the same cause, Richelieu was jealous of Corneille's laurels. The success which the fine tragedy *Le Cid* obtained "frightened him as much," Fontenelle says, "as if the Spanish army had been under the walls of Paris." He composed two plays: *Mirame*, a tragi-comedy; and *La Grand Pastorale*, both very indifferent performances. Richelieu, nevertheless, was a true friend to intellectual culture: he founded the *Académie Française*, enlarged the Sorbonne and the royal printing-office, built the College du Plessis, and established the botanical garden known by the name of Jardin du Roi. The only writings of his which will

really be found valuable, are his *Testament Politique*,³ his *Memoirs*,⁴ and his correspondence. Allusion has already been made to his sermons and to his controversial treatises: a man who mistook *Terentianus Maurus* for the title of a play, and translated it "The Moor of Terence," could not be deeply read in classical antiquity. But such matters are trifles in the history of him who conquered the Valteline, the duchy of Savoy, and La Rochelle, and whose genius prepared the peace of Westphalia and the treaty of the Pyrenees. The Bishop of Luçon was not the only remarkable man in the Richelieu family. One of his descendants earned an unenviable reputation as the greatest *roué* of the last century; whilst another, who died thirty years ago, played a conspicuous and most honourable part in the history of the Restoration. (G. M.)

RICHMOND, a market-town, parliamentary and municipal borough of England, in the North Riding of Yorkshire, occupies a beautiful position on a rocky height rising steeply from the Swale, here crossed by a stone bridge, 11 miles S.W. of Darlington, and 41 N.N.W. of York. The country around is richly wooded and very picturesque; and the romantic character of the place is enhanced by the old castle of Richmond, which stands to the south of the town, on the summit of cliffs which rise almost perpendicularly from the river. The Norman keep of the castle is still almost entire; the walls, 11 feet thick, rise to the height of nearly 100 feet. It was founded by Alan Rufus, Earl of Brittany, who came over with the Conqueror, and obtained from him the title of Earl of Richmond, along with the estates of the Saxon earl Edwin. The estates of Richmond became the crown property on the accession of that family in the person of Henry VII; but they were conferred by Charles II. in 1675 on his son Charles Lennox, in whose family it still remains. The town is irregularly laid out, and has one handsome broad street and a large market-place. The parish church is chiefly of Gothic architecture, but has some parts in the Norman style. A fine pinnacled tower rises from the west end. Trinity Chapel is a building of much antiquity, standing in the market-place. The other places of worship in the town belong to Wesleyans, Baptists, and Roman Catholics. There is a good town-hall, containing accommodation for the quarter-sessions, and a large assembly-room. The grammar-school of Richmond, incorporated by Queen Elizabeth, has six scholarships at Oxford, Cambridge, and Durham, and contained in 1854, 60 pupils. The town has also a corporation school, national and infant schools, a school supported by Roman Catholics, a scientific society, and a mechanics' institute. The manufactures of the place are not of much importance, consisting of a large paper-mill, iron and brass foundries, tanneries, rope-works, and corn-mills. The market for corn here is of some importance; and though the town is not at present in a very flourishing condition, it is the residence of many wealthy families, and stands in a region where there are many parks and seats of the nobility and gentry. The borough is governed by a mayor, 3 other aldermen, and 12 councillors, and returns 2 members to Parliament. Near the town there are some remains of an ancient monastery of the priory of St Martin, and of St Nicholas' Hospital. Pop. of the parliamentary borough (1851) 4969.

Richmond.

¹ *Cinq Mars, ou une conspiration sous Louis XIII.*

² The system adopted by Cardinal Richelieu has been very severely criticised by the following writers:—Edgar Quinet, "Philosophie de l'Histoire de France," *Revue des Deux Mondes*, 1855, tom. ix., p. 55; Ch. de Rémusat, "Richelieu et sa Correspondance," *Revue des Deux Mondes*, 1854, tom. v., p. 772; the same, "L'Ancien Régime et la Révolution, par M. Alexis de Tocqueville," *Revue des Deux Mondes*, 1856, tom. iv., p. 653; Alb. de Broglie, "Conclusions de l'Hist. de France," *Revue des Deux Mondes*, 1854, tom. v., p. 265; Alexis de Tocqueville, *L'Ancien Régime et la Révolution*. M. Caillet's volume, *De l'Administration en France sous le ministère du Cardinal de Richelieu* (Paris, 8vo, 1857), although rather too eulogistic, is very valuable, and full of most important details.

³ See on this book two valuable articles by M. Hyver de Beauvoir in the *Bulletin du Bouquiste* for 1857, pp. 211, 257.

⁴ See a series of very interesting papers by M. Avenel in the *Journal des Savants* for March and August 1858 and February and May 1859. The Cardinal's Memoirs were published for the first time in M. Peutot's collection, 1823.

Richmond.

RICHMOND, a town of England, in the county of Surrey, on the sides and top of a hill on the right bank of the Thames, 10 miles W.S.W. of St Paul's in London. On the summit of the hill stands the Star and Garter Hotel, and along the brow runs a terrace, both commanding a wide view over one of the richest and most beautiful tracts of country in England. In the lower part of the town the houses are small and old-fashioned; but there are many very handsome buildings in the more modern portions, and in the outskirts. The parish church is a plain brick edifice, with a low embattled tower. In it and the churchyard there are monuments to Thomson the poet, Kean the actor, Dr John Moore, and Gilbert Wakefield, who are buried here. The church of St John, built in 1831, is a good building in the pointed style. Independents, Baptists, Wesleyans, and Roman Catholics possess in the town places of worship; and there is a Wesleyan theological institution, occupying a very fine edifice in the Tudor style. There are in the town several schools, a literary and scientific institution, mechanics' institute, theatre, and savings-bank. Richmond Park, which lies to the south-east of the town, is inclosed by a brick wall, and has an area of 2253 acres. It is open to the public, the main entrance being at the west end of the terrace; and it is well stocked with deer. This is called the New Park; the Old Park, which extends along the river as far as Kew, being closed to the public. Richmond is much more remarkable as a place of pleasure and summer resort than as the seat of business or commerce. Being connected with the capital by railway, as well as by the river steamboats, it is resorted to by great numbers of visitors. It was for a long time the seat of royalty; and probably it is to Edward I. that this honour is owing. Henry V. rebuilt the palace in a magnificent style; but in the reign of Henry VII. it was burned down, and a new palace erected. This monarch changed the name of the place from *Sheen*, which it previously had, to Richmond, his own title before his accession. In that palace Henry VII. died in 1509, Charles V. was lodged in 1523, and Queen Elizabeth, who had been confined here by Mary, and afterwards made it a favourite residence, breathed her last in 1603. Under the Commonwealth, the palace was sold, and was demolished partly then and partly in the next century. Pop. (1851) 9065.

RICHMOND, a town of the United States of North America, capital of Virginia, on the left bank of the James River, 130 miles S. by W. of Washington, and about the same distance above the entrance of Chesapeake Bay. The general appearance of the town is very picturesque, somewhat resembling that of Edinburgh. It is divided into two parts by the valley through which Shockoe Creek flows into James River, and is built for the most part on the hills on either side. The streets are regular and the houses substantial, some of them very handsome. The most conspicuous edifice is the Capitol, a Grecian building after the model of the Maison Carrée at Nîmes, standing on the top of a hill in the midst of well-planted grounds about 8 acres in extent. It contains a statue of Washington by Houdon, considered the best likeness of that great man. At one corner of the Capitol grounds stands the City Hall, a fine Doric building; and not far off is the residence of the governor. Of the churches in the town, about 30 in number, many are handsome buildings. They belong to Baptists, Episcopalians, Methodists, Presbyterians, Quakers, Roman Catholics, &c. The educational establishments of the town include Richmond College, under the direction of the Baptists, with 6 professors and 167 students; the Virginia Baptist Theological Seminary, with 3 professors and 67 students; and the medical department of Hampden Sydney College, with 7 professors and 90 students. The last of these occupies a fine building in the Egyptian style. There are here, too, a historical and philosophical society,

Richter.

numerous schools, a court-house, penitentiary, alms-house, armoury, and orphan hospital. Richmond has great natural advantages for manufacturing industry, from the great amount of water-power supplied by the river. The articles most generally produced are flour, tobacco, cotton and woollen fabrics, paper, machinery, hardware, cannon, nails, &c. James River flows over a bed of granite, and has inexhaustible quarries on its banks, not far from the town; while within a short distance there are extensive deposits of coal. The trade of the town is rapidly increasing. It is the terminus of several railways, and of the James River Canal, which extends up the river for 200 miles. Vessels drawing 10 feet can come up to the town, and those drawing 15 to within 3 miles. Tobacco, wheat, and flour are the principal articles exported. The shipping of the district, June 30, 1852, amounted in all to 3078 tons registered, and 6100 enrolled and licensed. In the year ending on that day there entered from foreign ports 35 vessels, tonnage 7120; and cleared 71, tonnage 22,803. The aggregate value of the goods imported by railway and canal into the town is more than L.2,000,000. Richmond was founded in 1742, and became the capital of the state in 1779-80, but was then a small place, remarkable for nothing but the beauty of its scenery. Pop. (1800) 5737; (1820) 12,067; (1840) 20,153; (1850) 27,570, of which 17,643 were free, and 9927 slaves.

RICHTER, JEAN PAUL FRIEDRICH, was born 21st March 1763, at Wunsiedel, in the Fichtelgebirge, Bavaria, where his father, John Christopher Richter, was school-master and organist. Two years after, however, he was appointed parson at Joditz, and finally at Schwarzenbach. He appears in Jean Paul's fragment of autobiography as a clever, witty man, indulgent at home, prone to melancholy, and struggling all his life with debt. Jean Paul's education was conducted at home in an irregular fashion till his thirteenth year, when he was sent to the gymnasium at Hof. He had already acquired an amount of knowledge extraordinary for a boy, by dint of reading everything he could get to read in his father's library, and in the larger one of his friend Vogel, a neighbouring clergyman, and had commenced that system of making copious extracts from the books he read which he continued ever after. At Hof he lived with his mother's parents till the death of his father in 1780, which was shortly followed by the death of his grandfather and grandmother. To his mother, their favourite child, they left their property, which was considerable, in Hof, and she went there to reside. The will was contested by other expectants, and the expenses of the lawsuit and the debts of her deceased husband swallowed up the bequest, and reduced her to poverty. In these circumstances, Jean Paul was sent to the university of Leipsic, to study for the church, it being the ardent wish of his mother that he should follow his father's profession; and Leipsic was preferred to Erlangen on account of the supposed privileges of poor students at the former university. He entered 19th May 1781, and heard Platner lecture on logic and æsthetics, Morus on theology, Wieland on morals, and Hempel on the English language, to which he applied himself. It does not appear that he had at any time the serious intention of becoming a preacher, for his multifarious reading had already brought him under the influence of the scepticism of the time; but he seems to have been willing enough to fulfil his mother's desire, until his intercourse with the humorists of England—Addison, Swift, Pope, Young, Sterne—thoroughly awakened his powers into consciousness, and then it became his fixed resolve to live a literary life, and no other. Dire necessity pushed the resolve into premature action: want stared him in the face. The small sums his mother could afford to send him were insufficient for a bare subsistence; the letters in which he begs money or thanks her for it, consoling her, at

Richter. the same time, for her disappointed hopes of his becoming a preacher by the golden prospects of fame and independence to be won by his writings, are of a most pathetic cheerfulness. For his first book, *Lob der Dummheit* ("The Praise of Stupidity"), suggested (too obviously) by the *Encomium* of Erasmus, he could not find a publisher. In no-wise daunted, he threw it into the fire, and commenced a second *Gronlandische Prozessen* ("Greenland Lawsuits"), a series of satirical essays or sketches directed against German follies, and specially against the literary class. These first essays are certainly replete with wit, native and borrowed; and had he himself left nothing to compare them with, much more would be found in them. They were published by Voss at Berlin in 1783, and the author was made rich with 15 louis-d'ors. For a third volume he, after numerous solicitations, could find no publisher nor editor. In 1784 he returned to Hof, and lived with his mother in a very straitened way, cheerfully pursuing his studies, assisted by the books, and often by the money, of his friends Vogel and Otto. In Hof, while his eccentric freedom of dress (he wore his own hair and an open shirt-collar, and was otherwise wild in his attire) and of speech had made him enemies, he had a circle of warm friends, mostly of the fair sex, for whom he was already a great and wonderful man, before Weimar and Berlin had told them so. Two changes intervened before the dawn of his fame. In 1786 he became tutor in the family of a Von Oerthel at Topen, the father of a school and college friend between whom and Richter existed a warm affection. Here, however, he was rendered miserable by the disposition of his pupil and the arrogant narrowness of his employer; and on the death of his friend in 1789 he returned to Hof. It would appear that this occurrence produced a powerful impression on the mind of Richter: he himself dates from it as an epoch, and the recollection, varied and exalted by imagination, is repeated through all his works. Under the influence of this event he first struck the tone of profound melancholy and thoughtfulness, blending with higher hopes, which is the ground-tone of so much that is best in his works, in a little essay, *Was der Tod ist* ("What Death is"), which he sent to Herder, and which called forth an appreciating letter from Madame Herder, who received it. In 1798 he went to Schwarzenbach, on the invitation of his friends Cloter, Volkel, and Vogel, to teach their children, and resided alternately with each of them. Meantime he worked at a romance, *Die unsichtbare Loge* ("The Invisible Lodge"), which was published at Berlin in 1791, and which, though not very successful, brought him into notice among the cultivated. He himself described this romance as "a born ruin." But by the successive publication of *Hesperus* (1794), *Quintus Fixlein*, and the *Blumen, Frucht, and Dornen Stucke* ("Flower, Fruit, and Thorn Pieces"), 1796, he raised himself to a recognised place among the greatest writers of Germany, at a time when Herder and Wieland, Goethe and Schiller, were above the horizon at once. If we add *Levana* and the *Flegeljahre*, these are the works by which his name is best known out of Germany. A time of wandering followed,—residences in Weimar, where he especially attached himself to Herder, who reciprocated all his love; in Dresden, in Leipsic, and elsewhere; everywhere flattered and caressed, and finding access to the highest and most cultivated society. This severe trial of the successful author Richter met as a man of thoroughly-grounded self-knowledge and insight. Other trials he had with his fair admirers, who were numerous and ardent, and did not all understand his Platonic affection and doctrine of female friendship as he did, or were not so capable of its reserves. The fascination his writings exercised over female minds his presence and conversation completed: twice he had to say a resolute "No" to women who would marry him in spite

of himself; and in both cases the women—Madame von Kalb in Weimar, and Emilie von Berlespsh, a young and rich Swiss widow whom he met at Eger—were women of personal attractions, rank, and fortune. Richter wished, longed for a quiet retirement, where he might live his youth over again, not far from the very spot where its scenes first passed. He had no ambition of the worldly kind: quiet domestic joys, secured by his own exertions, were his ideal of happiness. In 1799 he formed an engagement with a young noble lady at the court of Hildburghausen. They were even betrothed; but the engagement was broken off, for reasons that did not transpire. Next year he met Caroline Meyer in Berlin; and on the 27th May 1801 he married her. The union was a happy one; their ideas of domestic happiness were the same; and she proved exactly the quiet, worshipping, careful *Hausfrau* whom Richter wanted and was seeking. In the meantime, he had published his *Palingenesien*, *Clavis Fichtiana*, some smaller works, and the first volume of *Titan* (1799). The *Clavis* had a success "of occasion" derived from the reputation of the object of the satire. Richter, who in respect of philosophy, was a follower of Jacobi, and to whom a personal Deity and a personal immortality were necessities of the heart, had no sympathy with the destructive logic of Fichte; and through his whole works may be found, now in exquisite ridicule (as in the man with the fixed idea that he has lost his *Ich*), now in deep and powerful protest (as in that truly appalling "Oration of Jesus Christ to the Universe," proclaiming that there is no God), evidences of his revolt from the new idealism. After a visit to Weimar, a year's stay in Meiningen, where he published the *Flegeljahre* ("Wild Oats," according to Carlyle), and a short residence in Coburg, he finally fixed himself (1804) at Bayreuth, where, near his dearest friend Otto, and in a house overlooking the Main, he spent the rest of his life as he had longed to do, diversifying it only by short annual tours to visit his scattered friends. During the heat of the war, when literature was at a discount, he felt the pressure of poverty, and solicited and received a pension of 1000 gulden (L.85) from the Prince-Bishop von Dalberg, paid, however, after 1811 by the Bavarian government. Of the works he published in these latter years, the most notable are the *Vorschule der Aesthetik* ("Introduction to Aesthetics"), 1813; *Levana*, a work on education, showing a remarkable insight into the nature of children, and full of the wisest practical suggestions; *Leben Fibels* ("The Life of Fibel"), 1812, a little work of strange humour; and *Der Comet oder Nicolaus Marggraf*, 1820-22. In 1811, already feeling the effects of incessant toil, he received a severe blow in the loss of his only son Max, at the age of nineteen. The youth had distinguished himself much at Munich, especially in languages, and went to Heidelberg, where he appears to have ruined his health by excessive study and needless privations. From this stroke he never completely recovered. His eyesight failing, he sent for his nephew, Otto Spazier, from Dresden, to assist him in revising his writings for a complete edition; and the work was only interrupted on the day of his death, 14th November 1825.

The affectionate adjective with which the Germans accompany the name of Jean Paul, *der Einzige* ("the Unique"), well denotes the difficulty of describing and the impossibility of classifying him. He is his own species, in a manner. That other common designation of him, as "a western oriental," is a real attempt at description; but it does not go beyond the mere first impression made on every reader of Jean Paul by the combination of contrasting qualities which he presents, by the copiousness of his imagery, by frequent obscurity, and by the boldness of his imaginative flights. The reason why so little that is definite can be said, beyond the expression of amazement and admiration,

Richter.

Richter. lies chiefly in the formlessness of his works,—a formlessness veiled and excused by the all-embracing atmosphere of pure ethereal humour in which they are as it were suspended, and which sweeps about them on all sides in copious mist-drapery. Taking for a moment a low and certainly unjust view of Jean Paul as a writer, it would seem as if, conscious of deficiency in the power of conceiving and representing the real, in constructing and narrating probable events, and in the dramatic synthesis of character, he employed his humour as artists unskilful in anatomy, but skilful in colour, employ drapery, to conceal those deficiencies, and allow him an opportunity of pouring forth, in digressive monologue, the precious stores of his wit and wisdom. Dropping the idea of purpose, such a supposition well enough describes the general character of Jean Paul's works. It is in fact the fault of the reader if he expects in any of them a coherent, probable story, probable characters well developed, dramatic dialogue and incident. But if he throw himself upon the contents alone, without fastidiousness, no author will more speedily repay studious and resolved perusal. A wealth of profound wisdom and keenest insight is contained in them, to the utterance of which a wonderful knowledge of nature and of science is compelled to minister, mirroring it in singular and typical forms. Further intimacy will acquit Jean Paul completely of all affectation, or use of humour for such purposes as above indicated, and will show it to be the compelled expression of a really powerful and Shaksperian soul, to which the vastness and the mystery of the universe, with the petty singularities of details, the noble and godlike attributes of humanity, with its infinite littlenesses and contradictions, were continually present together. Still, with the fullest appreciation of the rich compensation provided by the humour and the wisdom of Jean Paul, it is impossible not to note the deficiencies for which they compensate. In his great works *Hesperus* and *Titan*, the reader is painfully sensible that the story is absurd, that the characters are exaggerated and quite impossible, and that the ambition with which they are delineated ends in failure. Beside the story, and in the story, there is wisdom, and drollery, and poetry of the highest kind, enough to furnish forth with these things a library of fiction; but the story itself, and its men and women, are naught. Much better does he succeed in this way, when, without aspiring to produce heroes and heroines of the grand kind, who cannot act, and in whose mouths his finest sentiments are mere windy fustian, he simply relies upon self-delineation, and upon the recollections of the humble personages and the humble life in which he had been reared, and on which his observation, always fine and microscopic, had been exercised from boyhood. Nothing can be more perfect as comedy than the scenes of Siebenkäs, no character more true to life than Lenette; Walt and Vult in the *Flegeljahre*, Fixlein, Fibel, Schmelzle, are all in their way, and allowing for the necessary caricature, beings thoroughly human; and all are side-views of that Jean Paul whom he knew so well, and at whom he could laugh so heartily. But he is unsuccessful in supplying personages to complete his drama; and his story, after transacting itself for a short season on the solid earth, dissipates and ascends into the air as vapour, shapes itself into fantastic cloud-forms, and leaves the reader with elevated, perhaps, but also with disappointed look, gazing after it. Closely connected with this defect of structure, and allied to his dominating *humour*, are the serious defects of style in his works; and it is as much these faults as those of structure that render him so untranslatable, and consequently limit so much his influence and his fame. Beyond all the whims of mere humour, and all the requirements and value of the mere thought, his expression is far too frequently involved and overloaded. It is true, as Carlyle has remarked, that in the *Vorschule der Aesthetik*, which

may be considered his apology, there are excellent observations on this subject of style which show that he understood the subject as well as any French or German critic. Of subjecting himself to its laws, however, in practice, he has no idea; yet, if they are laws at all, they rise out of the nature of the thing. Of the judicious parsimony and restraint which is the first law of good writing Jean Paul has no notion. All the trifles and straws which he had gleaned out of a life's laborious reading of books, useful and useless, are whirled along in the current of his thought: cryptic and unintelligible allusions are huddled round this or that idea; the humour or aptness of many a comparison is lost, one side of it requiring for most readers, even well informed, elaborate explanation; we are astonished, we admire, but we neither laugh nor are much the wiser. It is absurd to gloss this copiousness and confusion of trifles, that no man cares to keep, with the name of intellectual wealth, for Richter would be none the poorer were it swept from his pages. His real wealth is not his learning, but his wisdom,—his knowledge of, and intense sympathy with, the human heart,—his fine sensibility and his elevated religion. As humorist, he is unquestionably to be placed in the highest rank. But he is something more. Mere humour, intellectually considered, is mere universal destructiveness. As wit, which is the compressed logic of analogy, when uncontrolled by truth, tends to juggling with analogical fallacy and mere paradox; so humour, which brings forth for sport's sake the innumerable contradictions, self-deceptions, illusions, and pretensions in the world, tends to utter scepticism and mere buffoonery, unless it has its work completed by the vision of faith which brings forward the eternal reality, and its hand checked by sympathy with real holiness and real suffering, and humble reverence for real greatness, nobleness, and elevation. Of the contradictions between free aspiration and necessity, none is more striking than that arising out of the demands of the moral nature of man and the urgencies of his passions; and these contradictions may be clashed against each other in sport. But it depends on the humorist on which side the laugh will be; and according as he is, will the laugh he raises be a degrading and deteriorating one, or an elevating and humanizing one. It is Jean Paul's highest merit, that a noble love of humanity, a keen sympathy with suffering, and a humble reverence for the truly great and holy, always subdued, controlled, and directed his wonderful powers of ridicule, and place him above the class of humorists, among the seers, the sages, and the comforters of humanity.

The complete works of Jean Paul were published after his death by his nephew Otto Spazier, to whom we are also indebted for a biographical commentary. A second edition of the works appeared at Berlin, 1840, in 33 volumes. The Paris edition, in 4 vols., 1837, is said to be a more faithful reprint of the original editions. A complete French translation was projected in 1834 by M. Philarette Chasles, but only four volumes, containing *Titan*, appeared. *Lerana*, portions of the *Flegeljahre* and of the *Blumen, Frucht, und Dornen Stücke* have been translated into English; *Quintus Fixlein*, by Carlyle, in his "German Romances," vol. 3, 1827, with a characteristic notice prefixed, which remains still the best word spoken on Jean Paul; the *Campaner Thal*, by Miss Gower, in 1857; besides many fragments and short sketches in magazines. (W. H. C.)

RICKMAN, THOMAS, an eminent architect, was the son of a surgeon and apothecary, and was born at Maidenhead in 1776. The early part of his life was spent in trying a variety of employments. He was first a druggist's assistant in London. He was then one of the men in an extensive grocery establishment at Saffron-Walden. Not long afterwards, in 1801, he went to Lewes to undertake a part of his father's business. There too his disposition remained unsettled. In the course of two years he was in the service

Rickman.

Rickmansworth || **Ridley.**
 of a corn-factor in the metropolis. At length, in 1808, he brought his wandering career to a close by settling down in Liverpool as clerk to one of the principal insurance-brokers in that city. It was about this time Rickman began to devote himself to the study of Gothic architecture. Every leisure hour was sedulously employed in his favourite pursuit. He examined ancient buildings. He classified the different modes of the pointed style. His hand also practised itself in designing monuments and other small erections for his friends. So far, indeed, did he carry his studies that he obtained the first prize for one of the government churches, and was thus induced to become at once a professional architect. Rickman removing soon afterwards to the more central town of Birmingham, took a high place in his new calling. There was scarcely a county in which his services were not employed. Among other edifices erected by him, there were St John's College, Cambridge; the church of Oulton, near Leeds; and the church of Hampton Lucy, near Stratford-on-Avon. At his death, in March 1841, he had perhaps designed more churches than any other architect. Rickman is the author of a popular treatise entitled *The Different Styles of Architecture in England*.

RICKMANSWORTH, or **RICKMERSWORTH**, a market-town of England, in the county of Hertford, on the Colne, 18 miles N.W. of London, and 23 S.W. of Hertford. It is a straggling place, and has a parish church recently rebuilt, but retaining the embattled tower of the older edifice. The Wesleyans and Baptists have also churches in the town. National and British schools afford means of education; and there are also Sunday-schools, almshouses, &c. Straw-plaiting and weaving of horse-hair fabrics are carried on; and in the vicinity there are flour, paper, cotton, and silk mills, mostly moved by water-power. Here too is a large brewery. Markets are held weekly, and fairs thrice a year. The Grand Junction Canal passes near the town. Pop. of the parish (1851) 4851.

RIDLEY, NICHOLAS, Bishop of London, and a martyr to the Reformation, was descended of an ancient family, and born in the beginning of the sixteenth century at Wilmontswick in Northumberland. From the grammar-school of Newcastle-upon-Tyne he was sent to Pembroke Hall in Cambridge in the year 1518, and was there supported by his uncle, Dr Robert Ridley, fellow of Queen's College. In 1522 he took his first degree in arts; two years after was elected fellow; and in 1525 he commenced master of arts. In 1527, having taken orders, he was sent by his uncle, for further improvement, to the Sorbonne at Paris; from thence he went to Louvain, and continued abroad till the year 1529. On his return to Cambridge he was chosen under-treasurer of the university; and in 1533 was elected senior proctor. He afterwards proceeded bachelor of divinity, and was chosen orator and a chaplain of the university. At this time he was much admired as a preacher and disputant. He lost his kind uncle in 1536; but was soon after patronized by Dr Cranmer, Archbishop of Canterbury, who made him his domestic chaplain, and presented him to the vicarage of Herne in East Kent, where, we are told, he preached the doctrine of the Reformation. In 1540, having commenced doctor of divinity, he was made king's chaplain; and in the same year was elected master of his college in Cambridge. Soon after, Ridley was collated to a prebend in the church of Canterbury; and it was not long before he was accused in the bishop's court, at the instigation of Bishop Gardiner, of preaching against the doctrine of the Six Articles. The matter being referred to Cranmer, Ridley was acquitted. In 1545 he renounced the doctrine of transubstantiation, and was made a prebendary of Westminster; in 1547 he was presented by the fellows of Pembroke Hall to the living of Soham, in the diocese of Norwich; and the same year was conse-

Ridolfi
 ||
Rienzi.

crated bishop of Rochester. In 1550 he was translated to the see of London. During the same year he was one of the commissioners for examining Bishop Gardiner, and concurred in his deprivation. In 1552, returning from Cambridge, he, unfortunately for himself, paid a visit to the Princess, afterwards Queen Mary; to whom, prompted by his zeal for reformation, he expressed himself with too much freedom; for she was scarcely seated on the throne when Ridley was doomed a victim to her revenge. With Cranmer and Latimer he was burnt alive at Oxford on the 16th of October 1555. Among other works he wrote *A Treatise concerning Images in Churches*; *A brief Declaration of the Lord's Supper*; *Certain godly and comfortable Conferences between Bishop Ridley and Mr Hugh Latimer during their imprisonment*; *A Comparison between the comfortable Doctrine of the Gospel and the Traditions of the Popish Religion*. The Life of Bishop Ridley was written by his relation, Dr Gloucester Ridley, in 1763.

RIDOLFI, CARLO, an eminent artist and writer on art, was born at Vicenza in 1602. His study of painting was characterised by shrewd practical common-sense. No narrow view of the subject would content him. He threw aside the false style of the Venetian school of that day, and strove to make his pencil imitate nature. He also sought instruction in studying the literature of painting. Nor did his sagacity forsake him when he came to be the biographer of artists. His style presented a favourable contrast with that of most of his predecessors. All tedious moralisings and childish fables were discarded. The only incidents brought forward were real facts clothed in precise language. His criticisms on pictures, too, were for the most part exact and judicious. Ridolfi is said to have died in 1658. His biographical work was entitled *The Wonders of the Art, or Lives of the Illustrious Painters of Venice and of the State*, in 2 vols. 4to, Venice, 1648.

RIENZI, NICOLÒ GABRINI DE, the deliverer of Rome, was born in that city about 1310. Although placed by fate in a humble station, the young man was by nature a prince. His noble mind could find its nourishment nowhere else than in the records of the ancient Roman glory. He pored over the battle-scenes and great forensic struggles described in Livy. He pondered among the remains of the queenly city of the Cæsars. As he meditated, the heroic spirit of antiquity came upon him. His imagination kindled with a desire for fame and power. His tongue grew inspired with the language of patriotism and liberty. It became, in fact, the ambition of his life to be the restorer of Rome to her former grandeur and renown. This aspiration of Rienzi's was confirmed by the daily sight of the deplorable condition of his fellow-countrymen. The Papal See had long since been removed to Avignon, and had left the city in a state of wild misrule. The people, a low, ignorant rabble, followed their own animal impulses. The nobles especially lived lives of armed violence and license. Their attendants were swaggering mercenaries from Germany, or desperate cut-throats from the Campagna. Their mansion-houses were fortified dens for thieves and murderers. From these they issued at intervals to gratify their headlong passions. They fought with each other in the streets, or committed rapine and outrage upon the defenceless citizens.

Rienzi having arrived at his prime, set himself to excite the people to throw off the yoke of their oppressors. His plan was to employ such means as would strike the dull sensibilities of the mob, without awakening the vengeance of the nobles. He therefore disguised all his proceedings under an appearance of eccentricity. As he lingered among the ruins, apparently wrapt in study, he would suddenly exclaim, in tones of intense regret, "Where are the old Romans? where is all their grandeur? why did I not live in those good times?" When the idle populace, startled by his voice, thronged around him with looks of

Rienzi.

curious wonder, he would tell them in words of eloquent enthusiasm about the deeds of their great ancestors. The stirring effect which these speeches produced among the mass of the people encouraged him to make his measures more direct. He exhibited in the streets and churches allegorical pictures of the state of the city, representing the nobles under the semblance of lions, wolves, and bears. He also assembled a meeting of the entire inhabitants at the church of St John Lateran, at which he showed from the ancient *Lex Regia* that the Romans had the right of making their own laws and of choosing their own rulers. At length his observant eye saw that it was time to bring the plot speedily to a crisis. About the beginning of May 1347 he met a hundred conspirators by midnight on the top of Mount Aventine, and exacted from them an oath of unqualified support. A few days afterwards he summoned the citizens to assemble on the evening of the 19th of the same month before the church of St Angelo. During all that night of suspense his form was seen taking part in thirty masses for the success of his enterprise. On the following morning he issued from the church with his head bare, with his body cased in armour, surrounded by the hundred accomplices, and preceded by banners which bore emblems of liberty, justice, and concord. As the procession wound along the streets, his kingly person, and pale and earnest countenance, called forth the acclamations of the attendant crowd. On reaching the Capitol, he mounted the rostrum, and, in a speech of resistless eloquence, announced to his fellow-citizens that he had come forward to be their deliverer. No sooner had he ended than he found that he had achieved the great desire of his life. The Romans with deafening applause declared him their ruler, sanctioned his laws for the establishment of the *good estate*, and placed their lives and their fortunes entirely in his hands.

Rienzi now began with success to inaugurate his rule. To identify himself with the cause of the people, he took the title of "Tribune." To conciliate the Pope, he assumed into partnership with himself the Bishop of Orvieto, the papal vicar. Thus countenanced by two of the great powers in the state, he addressed himself to the task of making regulations for restoring the healthy condition of the commonwealth. Courts were established for the redress of wrongs. Provision was made for the relief of the poor. A vessel was placed in each port to protect commerce. A standing force was also levied to guard the rights of the government. Nor did measures fail to be taken for the direct extermination of abuses. The nobles were compelled to dismantle their castles, disband their followers, and appear in the character of simple citizens. Every murderer and robber that infested the city was seized by the iron hand of justice. There was no respect of persons. Among others, the notorious freebooter Baron Martin Ursini was dragged from his bridal chamber in the morning, and before night he swung on a gibbet in the sight of the entire city.

The sudden rise and vigorous administration of Rienzi produced an effect almost unexampled in the history of the world. The terror of his name restored peace and prosperity in the commonwealth. There was no desperado or public pest so bold as to remain within several miles of the city. The very barons—the haughty Colonna and Ursini—trembled before the majesty of the low-born tribune. "Ye gods," says an eye-witness, "how they trembled!" His reputation as a righteous and powerful supporter of liberty even extended in a short time throughout and beyond Italy. The people knelt with reverence on the highways when they saw his ambassadors posting along with no other weapon than a white wand. The envious cities of Venice, Florence, Siena, and Perugia placed their lives and fortunes at his disposal. The haughty princes of foreign states sent messengers to seek alliance and friendship with

him. At length his renown reached a climax when Lewis of Hungary and Jane of Naples made him their umpire touching the murder of Andrew, the brother of the former, and the husband of the latter.

Rienzi.

It is no wonder that Rienzi, after such unparalleled success, became ostentatious and arrogant. What head would not have turned giddy after rising so suddenly and to such a height? The dream of his early ambition, he thought, was about to be realized. The sovereigns of the earth were already appealing to Rome as an arbiter. She was on the eve of becoming, as of old, the acknowledged queen of all cities. It was now time that in the person of her tribune she should formally assume the attributes of empire. If she did not, the ignorant and the envious might be slow to recognise her supremacy. He therefore resolved to show to the world by several unmistakeable deeds that he was the successor of the old Roman potentates. On the 1st of August, on the occasion of his going to the church of St John Lateran to be knighted, he got up a procession, adorned with every sort of pomp and pageantry, in imitation of the great shows of the ancient Cæsars. On the evening of the same day, in purifying himself for the ceremony, he bathed in the sacred porphyry vase which the Emperor Constantine had used. Nor did his presumption end there. When the multitude came next morning to the church to see him in his knightly insignia, he appeared, and, with a voice of imperial authority, summoned Pope Clement VI. and the Emperor Charles IV. to appear before his tribunal. Then drawing his sword, he pointed to the three quarters of the world, accompanying his action with the words, "This, and this, and this, is mine." This extravagant ambition of Rienzi's soon caused his downfall. The barons, provoked by his overbearing pride, fled from the city, levied forces, and wasted all the country round. He indeed defeated them; but the citizens became discontented at the bloodshed and scarcity of provisions. Taking advantage of this state of feeling, the Pope sent a legate to call him to account for his usurpation of the rights and territories of the church. His disdainful refusal to acknowledge such an arbiter only brought his difficulties to a crisis. He was immediately branded with the sentence of excommunication. The citizens, with superstitious dread, shrunk from his cause. Without opposition they allowed 150 of his enemies to enter the gates and take up a strong position in the quarter of the Colonna. In vain he called upon the people, with all the eloquence of desperation, to take arms in defence of the commonwealth. The listless looks with which they responded to his appeals told him that his power was at an end. He therefore resigned the tribuneship, and left the Capitol after a reign of seven months.

From this sudden and severe fall Rienzi rose up unsubdued and undespairing. His ambition was as sanguine and active as ever. He spent 1348 in wandering restlessly through Italy under the guise of a monk, and in seeking for aid to re-instate him in his former power. The next year's concealment among the peaceful hermits of the Apennines did not quiet his troubled desires. He ventured into Rome amid the throngs of the jubilee to look for hope among his former subjects. At length, when he found that his friends could not aid him, he adopted the daring resolution of trying to win the needed help from his most powerful enemies. Accordingly, in 1350 he appeared before the emperor at Prague, and, with the calmest self-confidence, declared himself to be "Nicolo Rienzi, the deliverer of Rome." It is true that his bold measure was apparently foiled; that the emperor sent him to the Pope; and the Pope cast him into prison at Avignon. But he remained hopefully in his cell for three years, quietly reading his Livy, and drawing from the historian many political lessons for his future use, when he should be restored to the government of Rome.

Rienzi's hope was destined to be fulfilled. Ever since

Riesenge-
birge
||
Rieti.

his abdication Rome had been plunging deeper and deeper into anarchy and misery. It soon became evident that none but he could restore order and prosperity. He was therefore taken from prison by Innocent VI., and sent back to govern his native state, with the title of "Senator." His entrance was a brilliant redress for his previous wrongs. The whole city had put on its holiday attire to welcome him. He rode along under triumphal arches, over flower-besprinkled roads, and through lanes of exulting citizens. His government was established in the Capitol amid the applauding sanction of the multitude, and the laws of the *good estate* were restored. But the elements of the Roman state were too worthless and conflicting to be formed into a durable republic, even by the master-hand of Rienzi. He soon found himself in the midst of ever-thickening embarrassments. The rebellious barons fortified themselves at Palestrina, and involved him in an expensive war. His exchequer was drained, without having any regular means of being replenished. The jealous papal legate Albornoz refused him supplies. The selfish and ungrateful populace were least of all willing to give him any aid. No sooner did he begin to tax them than they began to murmur. In this state of feeling they allowed themselves to be hurried by the emissaries of the barons into open rebellion against him. On the morning of the 8th October 1354, four months after his restoration, an excited mob invested the Capitol, yelling out, "Down with the traitor who laid on the imposts!" It immediately became evident that nothing but his blood would glut their vengeance. In vain he appeared at the balcony and tried to address them. They drove him back with missiles, and commenced to destroy the doors. In vain he sought to escape through the throng in disguise. They detected him, and set him up to view on the platform of the palace. There, indeed, the sad sight of the fallen and deserted hero kept them awestruck and silent for an hour; but no sooner did one of their ringleaders run him through the body, than they rushed forward in a mass to disfigure and insult his corpse with every display of malice.

The Life of Rienzi has been written in Italian by Forti-fiocca, in 4to, 1624; and in French by Ducerceau, in 12mo, Paris, 1722. An English translation of the latter work appeared in London in 1836. The subject has also been treated by Muratori and other Italian historians, and by Gibbon. Bulwer, in the Appendix to his splendid prose epic of *Rienzi*, has given several very plausible reasons for taking a higher view of his hero's character than the historical writers have done.

RIESENGBIRGE, or GIANT MOUNTAINS, a mountain chain of Germany, forming a part of the Sudetes, in the widest sense of that term, but a continuation of the chain strictly and properly so called. They extend from S.E. to N.W., separating Bohemia from Silesia, and rise above the Henschauer-Gebirge, which join it on the S.E., on the confines of Glatz, and the Iser-Gebirge, which form its continuation to the N.W. They are for the most part composed of granite and schist; and the scenery is very wild and romantic. The lower slopes are covered with forests of oak and beech; farther up, their place is supplied by pines; which in turn give place to shrubs and lichens. The principal summits are the following, arranged in their order from S.E. to N.W. :—

RIESI, a village of Sicily, at the foot of a mountain of the same name, in the province and 15 miles S. of Caltanissetta. There are sulphur mines in the vicinity. Pop. 6000.

RIETI (anc. *Reate*), a town of the Papal States, capi-

tal of a legation of the same name, stands on the slope and at the foot of a hill on the Velino, 42 miles N.N.E. of Rome. It is an ancient place, and contains a Gothic cathedral bearing the date 1456, but since then repeatedly altered. The town-hall (a large edifice in a lofty position), the episcopal palace, churches, convents, and college, are among the public buildings of the town, which is not so much remarkable for any architectural splendour as for the beauty of its situation, and many interesting remains of antiquity in the vicinity. Manufactures of woollen cloth, silk, leather, and glass are carried on here. Pop. 12,600.

The legation of Rieti is bounded on the N. by that of Spoleto, W. by that of Viterbo, S. by the Comarca di Roma, and E. by the Neapolitan province of Abruzzo Ultra; area, 528 square miles. It occupies the western portion of the ancient country of the Sabines, and is traversed by the mountain ridges which separate the valley of the Tiber from that of the Velino, the former of which rivers partly forms its S.W., and the latter its N.E. boundary. The mountain ranges are Monte Gennaræ, the ancient *Lucretius*, in the S.; and Mount Canterius in the N. Besides the Velino, this country is watered by its affluent the Turano, the ancient *Telonus*, flowing northwards from Naples. The plain of Rieti is exceedingly beautiful and fruitful, covered with woods and vineyards, fields of corn, pulse, hemp, flax, &c., and producing in abundance all kinds of vegetables. Pop. (1853) 73,683.

RIFLE. See GUNMAKING.

RIGA (Livonian, *Rihga*; Esthonian, *Ria Linn*), a fortified and seaport town of Russia, next to St Petersburg the most important place in the empire for maritime commerce, capital of the government of Livonia, stands near the mouth of the Duna, here 3000 feet broad, at the head of the Gulf of Riga or Livonia, about 180 miles N.E. of Königsberg, and 312 S.W. of St Petersburg. It is walled, entered by seven gates, and defended by a citadel. The town proper, inclosed within the walls, is quite German in character, with narrow, crooked streets, and houses with pointed roofs; but the suburbs, which cover a wide extent of ground on both sides of the river, have all a Russian appearance, having broad, straight streets, lined with wooden houses. Of the two imperial palaces, one, the oldest building in the place, was till 1561 the residence of the master of the Brethren of the Sword (*Schwertbrüder*), an order of knighthood which preceded the Teutonic in these countries. The beautiful hall where the estates of Livonia used to meet, the bomb-proof custom-house, council-hall, guild-hall, three arsenals, and theatre are among the principal buildings. The cathedral contains the tombs of the early bishops of Riga, and the church of St Peter has a fine dome and a tower 440 feet high, the loftiest in Russia, commanding a fine view of the Baltic, the broad, mast-covered Duna, the dark pine forests of Curland on the left, and the endless expanse of sand which forms the eastern shore of the Gulf of Riga. There are another Greek church, 3 Lutheran, 1 Reformed, and 1 Roman Catholic. The public library contains a chair of Charles XII., several letters of Luther, a cannon-ball said to have been fired by Peter the Great, and other curiosities. In front of the palace is a large square containing a granite column with a bronze figure of Victory, to commemorate the repulse of a French force from the town in 1812. There are spacious quays on both sides of the river, which is crossed by a bridge of boats; and an extensive harbour is formed by the 5 miles of its course between the town and the Gulf of Riga. The town has a grammar school, school of navigation, several elementary and other schools, literary and scientific associations, and benevolent institutions. The manufactures of Riga are numerous and important, including tobacco, sugar, leather, paper, starch, wool, cotton, playing-cards, &c. Gypsum is quarried in the vicinity.

Rights

The trade by sea is very great. Corn, linseed, hemp, flax, and timber are the principal articles of export. The number of vessels that entered in 1851 was 1706, and those that cleared 1720. The total value of the imports in 1851 was L.807,928, and in 1852 L.726,576; that of the exports in the former year L.2,271,395, and in the latter L.2,327,926. Riga was founded about the year 1200 by Adalbert, Bishop of Livonia, who was the founder of the order of Brethren of the Sword. This order obtained possession of Esthonia and Livonia, and were afterwards united with the Teutonic Knights. The city, which was mostly inhabited by Germans from Lubeck and Bremen, rapidly rose in wealth and influence; and in the thirteenth century became a member of the Hanseatic League. Riga was taken in 1621 by Gustavus Adolphus, and in 1710, after a vigorous resistance, by Peter the Great. On the latter occasion more than half of the town was destroyed; and in 1812 the suburbs and part of the town were burnt. It has suffered at several other times from floods and conflagrations. Pop. 70,463.

RIGAUD, HYACINTHE, sometimes called by his countrymen "the French Vandyck," was born at Perpignan in 1659, and studied painting at Montpellier, and afterwards at Paris. Although he gained the academy's first prize, which furnished him with the means of studying in Italy, he resolved to stay at home and practice portrait-painting. His bold, rich, and somewhat extravagant representations soon struck the attention of the public. In course of time he found a brilliant circle of patrons. Louis XIV. gave him a commission for a portrait. The princes of the blood, and the chief courtiers followed the example. Many illustrious personages in foreign lands also became his sitters. Nor did his fellow-artists fail to recognise his merit. He was successively professor, rector, and director of the academy. Rigaud died in 1742, leaving behind him many pictures, which are now scattered throughout the collections of Europe.

RIGGING, a general name given to all the ropes employed in a ship. Thus, those used to sustain the masts remain in a fixed position, and are called *standing rigging*; such are the shrouds, stays, and backstays. Those, again, which are employed to adjust the sails receive the general term of *running rigging*. Such are the braces, sheets, haliards, clue-lines, and brails.

RIGHT is a title conferred,—(1.) together with *Reverend*, upon all bishops; (2.) together with *Honourable*, upon earls, viscounts, and barons; (3.) by courtesy, together with *Honourable*, upon the sons of dukes, marquises, and the eldest sons of earls; (4.) together with *Honourable*, upon the speaker of the House of Commons, but upon no other commoner excepting those who are members of her Majesty's most honourable privy Council, and the three lords mayors of London, York, and Dublin, and the lord provost of Edinburgh, during their office.

RIGHT, *Petition of*, a parliamentary declaration of the liberties of the people assented to by King Charles I. (3 Car. I., c. 1). It was known as "the Petition" from being drawn up in that form, and was headed "The Petition exhibited to his Majesty by the Lords Spiritual and Temporal, and Commons, concerning divers RIGHTS and LIBERTIES of the subjects, with his Majesty's answer thereto." After reciting certain great rights and recent infringements of them, it prays that all such illegal acts be annulled, and that the popular rights and liberties, according to the laws and statutes of the realm, should be in future strictly observed. After some delay and evasion, the king replied in full Parliament, "Soit droit fait come est desiré."

RIGHTS, in the common acceptance of the word, are of various kinds; they are *natural* or *adventitious*, *alienable* or *inalienable*, *perfect* or *imperfect*, *particular* or *general*.

Natural rights are those which a man has to his life,

limbs, and liberty; to the produce of his personal labour; to the use, in common with others, of air, light, and water. That every man has a natural right or just claim to these things, is evident from their being absolutely necessary to enable him to answer that purpose for which he was made a living and a rational being.

Rights.

Adventitious rights are those which a king has over his subjects, a general over his soldiers, a husband to the person and affections of his wife, and which every man has to the greater part of his property. The existence of civil society evidently contributes in a great degree to promote the sum of human happiness; and therefore whatever is necessary for the support of civil society in general, or for the conduct of particular societies already established, must be agreeable to the will of God; but the allegiance of subjects to their sovereign, the obedience of soldiers to their leader, the protection of private property, and the fulfilling of contracts, are all absolutely necessary to the support of society; and hence the rights of kings, generals, husbands, and wives, &c., though adventitious, and immediately derived from human appointments, are not less sacred than natural rights, since they may all be ultimately traced to the same source.

Rights, besides being natural or adventitious, are likewise *alienable* or *inalienable*. Every man, when he becomes the member of a civil community, alienates a part of his natural rights. In a state of nature, no man has a superior on earth, and each has a right to defend his life, liberty, and property, by all the means which nature has put in his power. In civil society, however, these rights are all transferred to the laws and the magistrate, except in cases of such extreme urgency as leave no time for legal interposition. This single consideration is sufficient to show that the right to civil liberty is alienable; though, in the vehemence of men's zeal for it, and in the language of some political remonstrances, it has often been pronounced to be an inalienable right. "The true reason," says Paley, "why mankind hold in detestation the memory of those who have sold their liberty to a tyrant is, that, together with their own, they sold commonly or endangered the liberty of others; of which they had certainly no right to dispose." The rights of a prince over his people, and of a husband over his wife, are generally and naturally inalienable.

Another division of rights is into those which are *perfect* and those which are *imperfect*. Perfect rights are such as may be precisely ascertained and asserted by force, or in civil society by the course of law. To imperfect rights neither force nor law is applicable. A man's right to his life, person, and property, are all perfect; for if any of those be attacked, he may repel the attack by instant violence, punish the aggressor by the course of law, or compel the author of the injury to make restitution or satisfaction. A woman's right to her honour is likewise perfect; for if she cannot otherwise escape, she may kill the ravisher. Every poor man has undoubted right to relief from the rich; but his right is imperfect, for if the relief be not voluntarily given, he cannot compel it either by law or by violence. Here a question naturally offers itself: "How comes a person to have a right to a thing, and yet have no right to use the means necessary to obtain it?" The answer is, that in such cases the object or the circumstances of the right are so indeterminate that the permission of force, even where the right is real and certain, would lead to force in other cases where there exists no right at all. Thus, though the poor man has a right to relief, who shall ascertain the mode, season, and extent of it, or the person by whom it shall be administered? These things must be ascertained before the right to relief can be enforced by law; but to allow them to be ascertained by the poor themselves would be to expose property to endless claims. In like manner, the comparative qualifications of the can-

Rights
||
Rimini.

didate must be ascertained before he can enforce his right; but to allow him to ascertain his qualifications himself, would be to make him judge in his own cause between himself and his neighbour. Where the right is imperfect on one side, the corresponding obligation on the other must be imperfect likewise. The violation of it, however, is often not less criminal in a moral and religious view than of a perfect obligation. It is well observed by Paley that greater guilt is incurred by disappointing a worthy candidate of a place upon which perhaps his livelihood depends, and in which he could eminently serve the public, than by filching a book out of a library, or picking a pocket of a handkerchief.

Rights are *particular* or *general*. Particular rights are such as belong to certain individuals or orders of men, and not to others. The rights of kings, of masters, of husbands, of wives, and in short all the rights which originate in society, are particular. General rights are those which belong to the species collectively. Such are our rights to the vegetable produce of the earth and to the flesh of animals for food. If the vegetable produce of the earth be included under the general rights of mankind, it is plain that he is guilty of wrong who leaves any portion of land waste merely for his own amusement; he is lessening the common stock of provision which Providence intended to distribute among the species. On this principle it would not be easy to vindicate certain regulations respecting game, as well as some other monopolies which are protected by the municipal laws of most countries. Dr Paley, by just reasoning, has established this conclusion, "that nothing ought to be made exclusive property which can be conveniently enjoyed in common." An equal division of land, however, the dream of some visionary reformers, would be injurious to the general rights of mankind, as it may be demonstrated that it would lessen the common stock of provisions, by laying every man under the necessity of being his own weaver, tailor, shoemaker, smith, and carpenter, as well as ploughman, miller, and baker. Among the general rights of mankind is the right of *necessity*, by which a man may use or destroy his neighbour's property when it is absolutely necessary for his own preservation. It is on this principle that goods are thrown overboard to save the ship, and houses pulled down to stop the progress of a fire. In such cases, however, there must be restitution when it is in our power.

RIGHTS, *Bill of*, a declaration delivered by the Lords and Commons to the Prince and Princess of Orange, 13th February 1688; and afterwards enacted in Parliament when they became king and queen. It sets forth that King James did, by the assistance of divers evil counsellors, endeavour to subvert the laws and liberties of this kingdom, by exercising a power of dispensing with and suspending of laws; by levying money for the use of the crown by pretence of prerogative without consent of Parliament; by prosecuting those who petitioned the king, and discouraging petitions; by raising and keeping a standing army in time of peace; by violating the freedom of election of members to serve in Parliament; by violent prosecutions in the Court of King's Bench; and causing partial and corrupt jurors to be returned on trials, excessive bail to be taken, excessive fines to be imposed, and cruel punishments to be inflicted; all which were declared to be illegal. And the declaration concludes in these remarkable words: "And they do claim, demand, and insist upon, all and singular the premises, as their undoubted rights and liberties." And the act of Parliament itself (1 Will. and Mary, stat ii., cap. 23) recognises "all and singular the rights and liberties asserted and claimed in the said declaration to be the true, ancient, indubitable rights of the people of this kingdom."

RIMINI (anc. *Ariminum*), a town of the Papal States, legation of Forli, near the mouth of the Marecchia in the

Adriatic, 24 miles E.S.E. of Forli. It is entered from the N. by the bridge of Augustus over the Marecchia, and from the S. through the triumphal arch of the same emperor, both of white marble, in the best style of architecture. These form the only undoubted remains of the ancient grandeur of the place; for the pedestal in the market-place, said to have been used as a pulpit by Cæsar after he had crossed the Rubicon, is probably not genuine. The cathedral church of St Francesco, built in the fourteenth century, and re-modelled in the middle of the following one by Sigismund Pandolfo Malatesta, is the chief edifice of the town, an interesting example of the transition from the Gothic to the classic style. The Gothic windows on the side of the building are concealed by seven arches, under which are as many tombs of illustrious friends of the architect. The interior retains little of its original pointed architecture; it is richly adorned with sculpture, and contains many interesting monuments. The other churches and the palaces contain many fine paintings. There is a fortress, and a public library of 30,000 volumes. The house of Francesco da Rimini associates this town with one of the most beautiful parts of Dante's poetry. Silk fabrics, glass, and earthenware are manufactured; and the trade was once of much importance, but the ancient harbour is now choked up with sand, and there is but little traffic in corn, fish, salt, silk, &c. Ariminum was originally an Umbrian city, but fell into the hands of the Gauls, from whom it was wrested, and a colony established, by the Romans in 268 B.C. It was important as a military post and seaport; and at a later period was connected with Rome and Placentia by the Flaminian and Æmilian roads. In most of the subsequent wars in Italy it played a conspicuous part, commanding Cisalpine Gaul and the E. coast of Italy. After the fall of the Western Empire, still a flourishing city, it formed part of the Pentapolis, under the exarchs of Ravenna, until the Lombard invasion. It subsequently came under the German emperors; and in 1200 Malatesta was made viceroy, and his descendants for some time enjoyed that dignity. The town subsequently passed into the hands of Venice, and finally into those of the Pope. Pop. 13,000.

RINCON, ANTONIO, an early Spanish painter, was born at Guadalajara in 1446. His career was attended with complete success. Eschewing the stiff Gothic style of his age and country, he soon rose to the first place in his profession. Ferdinand and Isabella gave him the order of Santiago, and made him their painter in ordinary. Till his death in 1500, he continued to be employed on public pictures, which have all since perished.

RINGWOOD, a market-town of England, Hampshire, in a flat country, on the left bank of the Avon, which spreads out here into a broad sheet of water, with many islands, on the skirts of the New Forest, 20 miles W.S.W. of Southampton, and 92 S.W. by W. of London. It is an old but generally well-built town, containing a parish church, part of which dates as far back as 1230; other churches belonging to Wesleyans, Independents, and Unitarians; a grammar school, and national schools. Woollen cloth, hosiery, and beer are made here; markets for corn are held weekly, and fairs for horses and cattle twice a year. The town was in existence as early as the times of the Romans, and was a place of some importance under the Anglo-Saxons. Pop. of the parish (1851) 3928.

RINGWORM is a disease of the skin, which appears in small circular patches, or rings of vesicles round the circumference of a circle of apparently healthy skin. These vesicles are small, and contain a transparent fluid, which is discharged in three or four days, when little dark scabs form over them. Sometimes there is a succession of the circles on the upper parts of the body, as the face and neck, and the arms and shoulders. The more formidable and

Rincon
||
Ringworm.

Rio de Janeiro.

infectious species of ringworm appears in distinct patches of an irregularly circular figure, on the scalp, head, and neck. It generally occurs in children of three or four years old and upwards, and often continues for several years. While the patches are in an inflamed and irritable condition, we must be content with regular washing or sponging with warm water, or some emollient fomentation. The application of a solution of one drachm of nitrate of silver in half an ounce of diluted nitric acid has been well recommended. The constitutional treatment is of consequence. A nutritious diet must be prescribed, containing a due admixture of animal food; the clothing must be warm; regular exercise must be enjoined; and a course of tonic medicines, such as iron or quinine, must be ordered.

RIO DE JANEIRO, an important province of Brazil, is bounded on the N. by Espiritu Santo, from which it is separated by the River Capabuan, and by Minas Geraes, from which it is divided by the rivers Preto and Parahiba, and in part by the Serra da Mantiqueira; on the W. it borders on San Paulo; and the Atlantic Ocean washes it on the S. and E. It lies between S. Lat. 21. 23. and 32. 20., W. Long. 40. 53. and 44. 40. Its area is estimated at 18,226 square miles. This province is distinguished for its romantic beauty and great fertility, notwithstanding its being very mountainous. From S.W. to N.E. run the Serra dos Orgaos, or Organ Mountains, and this chain divides it into two nearly equal portions; the northern half sloping gradually to the Parahiba, and the southern to the sea-coast. The Organ Mountains derive their appellation from the appearance of the pyramidal heads of granite which bristle up along the horizon, and bear a fanciful resemblance to organ-pipes in a vast cathedral. The whole province is well watered by a number of streams, the most considerable being the Parahiba. This river originates in a small lake in the southern part of the Serra da Bocania, a continuation of the Organ Mountains, in the province of San Paulo; and after a long and winding course it enters that of Rio de Janeiro, and falls into the Atlantic in its N.E. part. Many streams discharge themselves into the bay of Rio towards its upper end, several of them being navigable to some distance. The country is also watered by the affluents of the Parahiba, and by many rivers which flow into the Atlantic. There are many lakes and lagoons, especially in the N.E., where the coast is low and monotonous. Towards the S., and especially near the capital, the scenery is of a very different and more picturesque character.

The principal bays by which the coast is indented are the bay of Rio de Janeiro, and Angra dos Reis, or King's Bay. The bay of Rio is stated to be no less than 32 miles in circumference, and on its shores are numerous smaller inlets, which may be termed sub-bays. All travellers agree in praising the surpassing grandeur and beauty of this majestic inlet of the sea. The capacious basin is embosomed among elevated mountains, which have conical summits, and, being well wooded, have a romantic and picturesque beauty. Some of these advance a considerable distance into the bay, whilst others retire as far inland, leaving between them deep recesses and glens. The entrance of the bay is narrow, being only about a mile in breadth; and its granite barriers are so bold, causing it to resemble a gap or chasm in the mountain ridge, that doubtless it was often passed by early navigators without their apprehending the existence of such an immense salt-water lake within. Being completely land-locked, and protected from gales on every side, it is perfectly secure, even for boats, at all seasons of the year; from which circumstance, as well as from many other advantages which it possesses, it has been pronounced the finest harbour in the world. It is so well defended by strong forts that it seems completely closed against a hostile force. The bay

Rio de Janeiro.

is studded with about a hundred islands, on many of which are forts. That of Ilha dos Cobras, or Snake Island, is of great strength, and constitutes one of the most commanding points for the defence of the city. In short, the Brazilians and early subjugators of the country have carefully availed themselves of every advantage presented by nature for rendering their capital unassailable by a maritime force. On either side the shores of the bay, lined at the water's edge with cottages and hamlets of fishermen, sweep widely round; while behind, hills in the richest state of cultivation, studded with farm-houses and villas, and crowned with churches and monasteries, all of purest white, rise abruptly on every side, till, a few miles inland, they terminate in the hold, beautiful, and picturesque ranges of the Organ Mountains.

With the exception of the capital, there are few places in the province of Rio which require particular notice, Canto Gallo is the capital of a district of amazing fertility, and carries on considerable trade with Rio in the productions of the soil. Porto d'Estrella and Mage are the names of other towns which have much traffic with the capital. The productions of this province comprise almost everything for which Brazil is celebrated; diamonds and precious stones, sugar, coffee, cotton, and, in short, all fruits peculiar to the tropics, are here produced in the richest abundance, and of the most excellent quality. The forests yield great quantities of timber, used for various purposes; gums, balsams, and medicinal herbs are not wanting. Gardening is much attended to; and the extension of cultivation is gradually clearing the land of the wild beasts that still haunt the forests. Cattle and horses are bred in great numbers. The province is divided into eight comarcas. Its provincial assembly of 36 members meets at Nitherohi, opposite Rio de Janeiro. It is represented in the legislature of Brazil by 6 senators and 12 deputies. Pop. (1856) 1,200,000.

RIO DE JANEIRO, formerly *St Sebastian*, the capital of the above province and of the Brazilian empire, is situated on the south-western side of the bay or harbour just described, about 4 miles from its entrance; S. Lat. 23. 54., W. Long. 43. 9. It occupies the N.E. part of a tongue of land of an irregularly quadrangular shape, and extending on an inclined plane a short distance into the bay. The site selected for their town by the early settlers is considered the best that could have been chosen, out of many excellent ones that everywhere present themselves. Its most easterly point is the Punta do Calabouco; the most northerly is the Armazem do Sal, opposite to which is the small island of Ilha dos Cobras. The most ancient and important part of the city is built between these two points, lying from N.W. to S.E.; and a beautiful quay, constructed of solid blocks of chiselled granite, stretches along the shore. The houses of Rio are neatly and substantially built, generally of granite, and two storeys high, with little wooden balconies in front. Their lower storeys are commonly occupied by shops and warehouses, and the upper ones by the family apartments. The whole town is disposed in squares, the streets crossing each other at right angles, and, although narrow, they are well paved, and lined at each side by flagged trottoirs. In its style of architecture the old town is in general mean, resembling the old part of Lisbon; but the new town is in a much more handsome style. Although this town has always ranked as the most important in Brazil, or as second only to Bahia at the time when the latter was the seat of government, yet it was only after the imperial residence and the court were fixed here that it assumed the character of a European city. Great improvements took place after that event. The new town has almost wholly sprung up since it occurred. This part of Rio is connected with the south-western quarter, or Bairro de Mato-porcos, by the bridge of St Diogo, thrown over a salt-water inlet. Between the

Rio de
Janeiro.

old and new town is situated a large plain nearly surrounded by an amphitheatre of mountains, clothed at their bases with the richest verdure, and terminating by belts of forest-trees of immense growth and of every variety. One of these elevations is called the Corcovado, or Broken Back, an appellation which it acquired from its extraordinary and fantastical shape. The plain thus environed is inclosed with houses so as to form an enormous quadrangle, perhaps the largest square in the world. Here are erected the senate-house, the museum, the camera or town-hall, and other public buildings. One of the most striking features of the Brazilian capital is the number of its churches and monasteries, which not only abound in the city, but are seen crowning almost all the surrounding eminences. Among the former, the most conspicuous are the cathedral of La Gloria, an octagonal building crowning a lofty wooded hill; the majestic church of Candelaria, the largest in the town, and surmounted by the loftiest towers in Brazil; the richly-ornamented church of the Cross; and that of Sao Francisco, with its two round towers. The convent of St Anthony is a large and gorgeous edifice; and that of Sao Bento is so richly adorned as to be one mass of gilding in the interior.

Near the centre of the quay, which has already been mentioned, there is a large square, surrounded on three of its sides with buildings, but having its fourth open to the bay. In this square the palace or imperial residence is situated; but although extensive in its dimensions, and commodious and even splendid in its internal arrangements, there is nothing magnificent or striking in its architecture. The public library occupies a suite of rooms in this quarter. It contains sixty or seventy thousand volumes in all languages, and is considered a very admirable collection. On the quay in front of the square is a very beautiful fountain for supplying water to this part of the city, and to the shipping in the harbour. It is fed by a splendid stone aqueduct leading from the Corcovado Mountain, not more striking for the magnificent singularity of its appearance than important for its utility. This great work, which is called Arcos de Cariaco, extends across a deep valley, resting on a double tier of lofty arches placed one above the other to the height of 90 feet, and the water is conducted to the reservoir by a succession of stone troughs laid on the top of this bridge, under an arched covering of brick-work. Each tier comprises forty-two arches, the upper one extending 280 yards. The following is the provision made for education:—A military academy, a naval academy, a surgical and medical academy; an academy of the fine arts (in connection with which we may mention a national museum), and lastly, two ecclesiastical seminaries, where the ancient and modern languages are taught, as well as divinity and the sciences. Besides these, there are several superior and numerous primary schools. In periodicals and newspapers the city is by no means deficient; and book-printing is carried on, although not extensively. Government has a printing establishment. There is a large botanic garden, well laid out and rich in exotics, at some distance from the town.

The trade of Rio is very great, and rapidly increasing. The export of coffee from this port is equal to that from all the others in the world, amounting in 1856 to 8,683,120 cwt., valued at L.4,788,000. In the same year there were exported 14,338 carats of diamonds and precious stones, L.53,680 worth of timber, L.59,040 worth of calves' leather, L.40,120 worth of spirits, as well as quantities of tapioca, sarsaparilla, ipecacuanha, horns, &c. The principal articles imported in 1854 and 1855 were as follows:—

	1854.	1855.
Estables—corn, butter, &c.	L 954,000	L 1,263,840
Cotton fabrics	1,250,000	1,206,800
Liquors—wine, tea, &c.	692,000	767,160
Woollen fabrics	292,000	547,400

Rio Grande

	1854.	1855.
Coal and metals	444,000	413,200
Watches, jewellery, cutlery, &c...	404,000	395,600
Wood, furniture, &c.	348,000	354,400
Hats, haberdashery, &c.	356,000	298,480
Silk fabrics	316,000	310,400
Linen fabrics	154,000	223,000
Paper and books	162,000	185,720
Pottery, porcelain, &c.....	112,000	171,600

The value of the exports and imports in 1855, arranged according to the different countries, is exhibited in the following table:—

Countries.	Imports.	Exports.
Great Britain and colonies ...	L.2,404,800	L.2,055,360
United States ..	879,240	3,362,920
France ..	1,348,000	733,640
Hanse Towns	498,800	678,240
Portugal	598,080	209,680
Austria	46,720	206,760
Belgium	277,160	442,840
Spain ..	220,600	24,800
Sweden and Norway	160,840	78,000

Totals in 1854 ..	6,836,000	6,460,800

The number of vessels that entered the port in 1856 was 3620, of which 2250 were from foreign ports; that of those that cleared was 3622.

The manufactures of the town are unimportant, notwithstanding the repeated attempts of the government to foster them. Leather and glass are the only articles produced in any great quantities. The climate is considered as favourable to health, comfort, and even longevity, as that of any other place between the tropics. During the summer months, which may be reckoned as extending from October to April, heavy rains fall; but on the whole few places possess a more beautiful climate than this celebrated city.

The bay of Rio was discovered on the 1st of January 1531 by Martin Alphonso de Sousa, a Portuguese navigator. The natives had given to this tranquil basin the significant appellation of *Nitherohi*, that is, "hidden water;" but he, supposing it the estuary of some great river like the Orinoco, called it the *Rio de Janeiro*, after the day on which it had been discovered. It remained many years unnoticed or unoccupied by the Portuguese, but in the meantime was taken possession of by France, and became an asylum for the persecuted Huguenots. These were subsequently expelled by the Portuguese, who, in 1567 founded the city of Rio. It steadily advanced in riches and importance; so that in the year 1763 Dom Joseph was induced to transfer hither the viceregal residence from Bahia, hitherto the capital of the province of Brazil. In 1808 it became the residence of the Portuguese court; and in 1822 was constituted the capital of the independent empire of Brazil. In 1831 it was the theatre of a revolution, in which 6000 armed citizens were joined by the troops of the line in their opposition to the government, and in consequence of which Dom Pedro abdicated the throne in favour of his son Pedro II. Pop. (1851) 205,906, of whom 77,989 were native white men, 36,329 foreign white men, 10,722 free coloured men, and 78,835 slaves; (1855) 296,136.

RIO GRANDE, a river of West Africa, Senegambia, rises in the mountains of Fouta Jallon, near the sources of the Senegal and Gambia, and flows in an irregular course westwards to the Atlantic. It enters the sea by several branches, broad, rapid, and navigable, though somewhat obstructed by shoals. The most northerly of these branches

Rio Grande is called the Jeba or Geba, a name sometimes applied to the whole river. The upper course of the Rio Grande has been very little explored. Its banks are well wooded, and studded with large ant-hills; and the neighbouring country is rich in many valuable productions.

RIO GRANDE DO NORTE, a province of Brazil, is bounded on the S. by Paraíba, on the N. and E. by the Atlantic Ocean, and on the W. by Ceara. Situated between the parallels of 4. 30. and 6. 45. of S. Lat., the climate is of course very hot. At Cape St Roque, which forms the angle of this province, in Long. 36. 15. W., Lat. 5. 7. S., the coast of Brazil terminates towards the N.E.; and the Atlantic Ocean, which has so long been its boundary on the E., begins to wash its northern shores. The province has about 100 miles of sea-coast, and an area of 31,230 square miles. The Rio Grande, or Potengi, the great river of the province, rises in a ridge on its western limits, and traverses its whole extent in a direction from S.W. to N.E. The province is irrigated by other streams, on whose banks the most fertile land is to be found; but the soil in general is rather sterile. None of the rivers are of any great size. There are several salt lakes, which afford much excellent salt. It is mountainous in the S. and W., but gradually slopes toward the sea; and along the coast there is an expanse of low sandy ground. Cotton is the crop that grows best in this country; but maize, mandioc, rice, and the sugar-cane are also raised. The minerals include gold, silver, iron, limestone, sandstone, granite, &c.; but mining is only carried on to a very small extent. There are numerous small harbours along the coast; but navigation is interrupted by many shoals, some of them very dangerous, which line the shore. The small island of Fernando de Noronha, about 250 miles E.N.E. of Cape St Roque, belongs to this province, and is used as a place of transportation. Salt, cotton, sugar, hides, salt fish, &c., are exported from Rio Grande do Norte. The capital, Natal, is the seat of the provincial assembly of twenty members. The province sends one senator and two deputies to the legislative assembly of Brazil. Pop. (1856) 190,000.

RIO GRANDE DO SUL, or *S. Pedro do Rio Grande*, the most southerly province of Brazil, bounded on the N. by the provinces of Cuntuba and S. Catherina, E. by the Atlantic, S. by Uruguay, and W. by La Plata, lying between S. Lat. 25. 30. and 32. 30., W. Long. 49. 40. and 58. 20. It is upwards of 500 miles in length by 400 in breadth, and has an area of 118,758 square miles. This extensive country consists chiefly of large plains covered with immense herds of cattle and other animals. Some mountain ridges traverse it in various directions, but none of them is of any great height. Here several large rivers have their origin, of which the Uruguay, the Jacuhy, and the Camapuam, are the most important. Its great extent of level and alluvial coast exhibits some lakes of vast dimensions. The Lagoa dos Patos is the largest lake in Brazil, being 140 miles in length from N.E. to S.W., and about 40 miles in breadth. This lake is the recipient of almost all the streams which irrigate the northern and eastern portions of the country. It is very shallow, and its water continues fresh as far as the Island dos Marinheiros, near the port of S. Pedro. The peninsula lying between the lake and the ocean is low and level, and its eastern side lies almost in a direct line, but the opposite side forms various points and bays. The western shore of the lake is bold but not rugged, and is cut by several rivers, of which the Camapuam and Jacuhy, already mentioned, are most deserving of notice. The sources of the former are in a chain of low hills called the great Cochilha, which traverses the western limits of the country. It flows with a rapid and disturbed current, interrupted by continued cataracts for nearly 100 miles, and falls into the lake about the middle of its western side. The Jacuhy is a river of still greater

value. It rises in the north of the province, and after traversing the southern declivity of the general ridge for several miles, it turns eastward, describing innumerable windings for a course of about 80 miles, during which it collects the water of a number of smaller rivers, many of them navigable. It then suddenly bends towards the S., and after running 15 miles in this direction, enters the lake not far below its northern extremity. To the S.W. of the Lagoa dos Patos lies another sheet of water, called Lake Mirim. It is 90 miles in length by about 20 in breadth, and discharges itself into the Lagoa dos Patos by means of a channel called the river of St Gonzales. Lake Mirim is very shallow, and in the rainy season it widely extends its borders. The Gonzales is 50 miles in length: it is wide and handsome, and navigable for small vessels, which by this channel pass into Lake Mirim, and thence by means of rivers penetrate into the fertile interior, and distribute their cargoes to the large towns on the coast. There are other large lakes running parallel with the shore, but these are the most important.

The climate of the province is mild and healthy; the greater part of the soil is fertile, and produces various kinds of grain, and many of the fruits of Europe. Timber is not very abundant, but of very good quality. Among the minerals are gold, silver, iron, sulphur, and porcelain clay. The rearing of cattle, however, is what chiefly distinguishes the country, and gives employment to its inhabitants. They are either slaughtered to form the salt beef for the export of which the province is celebrated, or sent in droves to Sao Paulo and Rio Janeiro. Horses and mules are bred to a great extent, and are highly valued for the excellence of the breed. The provincial assembly of Rio Grande do Sul consists of twenty-eight members; and the province sends to the Brazilian legislature three senators and six deputies. Pop. (1856) 201,300.

The capital, Rio Grande do Sul, or S. Pedro do Sul, formerly stood a few miles from where it now stands, in the situation called Estreito, near the head of a bay or harbour, at the entrance of the Lagoa dos Patos; but the encroachment of the sands has made such progress as almost to have overwhelmed the town, and occasioned its removal to the present site. It is now situated on a level plain a little above high-water mark; but, like its predecessor, it suffers much from the accumulation of sand. Its public buildings comprise a plain but handsome cathedral, several other edifices, and a fort. Its commercial importance appears to be considerable. Large quantities of wheat, hides, tallow, dried beef, cheese, and other articles are shipped from this port, and commerce is rapidly increasing. Pop. of the town, 3560; of the district, 12,000.

RIOJA. See *PLATA, La*.

RIOM, a town of France, capital of an arrondissement in the department of Puy-de-Dôme, in a rich and beautiful country, on a hill above the Ambone, 8 miles N.N.E. of Clermont. It is encircled by boulevards shaded by trees, and has a cheerful aspect, though built of dark lava from the neighbouring quarries of Volvic. The streets are broad, and the houses generally are well built. Many of the public buildings, such as the court-house, prefect's residence, hospitals, &c., are very handsome; and the church of St Amable is a curious and interesting old edifice. On one of the boulevards of the town is a granite monument to General Desaix, who fell at the victory of Marengo. Riom is the seat of several law courts and of a college. It has manufactures of linen fabrics, leather, brandy, and other articles; and a considerable trade in these, as well as in corn, wine, fruit, oil, &c. It was formerly the capital of Auvergne, and the old ducal palace is now the court-house. Pop. (1856) 10,078.

RIONERO, a town of Naples, the largest in the province of Basilicata, on the slopes of two hills and the inter-

Rioja
||
Rionero.

Ripley
||
Ripperda

vening valley, 8 miles S. of Melfi. It is remarkable for nothing so much as for the traces which about half of the town retains of the terrible earthquake which desolated this place and the surrounding district in 1851. There are several churches and a convent. Wooden snuff-boxes are manufactured, and some trade in oil and wine is carried on. Pop. 9600.

RIPLEY, a market-town of England, in the West Riding of Yorkshire, 18 miles N. of Leeds, and 25 N.N.W. of York. It stands on the Nidd, which is here crossed by a bridge, and is neatly and well built. There is a large cruciform church, containing many tombs of the Ingilby family, who reside in Ripley Castle, one of the chief ornaments of the town. This family residence was built in 1855; and it was here that Cromwell spent the night before the battle of Marston Moor. Pop. of the parish (1851) 1286.

RIPON, a market-town, parliamentary and municipal borough of England, in the West Riding of Yorkshire, on the right bank of the Ure, 23 miles N.W. of York, and 215 N.N.W. of London. It stands in the midst of a rich and well-wooded country, and consists of irregularly laid-out streets, many of which meet in the spacious market-place near the centre of the town. Here there is a handsome town-hall, and an obelisk 90 feet high, surmounted by the city arms. The principal edifice is the cathedral, one of the best proportioned churches in the kingdom. Its whole length is 260 feet, that of the transept 132 feet, the breadth of the nave and aisles 87 feet, and that of the choir and aisles 66 feet. At the west front two uniform towers rise to the height of 110 feet; and in the centre is a large but lower one, called St Wilfred's Tower. Under the chapter-house is a vault containing a great number of human remains in good preservation. The architecture of the church is partly Norman and partly early English; the building was begun in 1331, but not completed till 1494. Besides Trinity church, an early English cruciform building, erected in 1826, there are in Ripon, Wesleyan, Primitive Methodist, and Independent churches. The educational establishments comprise a free grammar school, national and infant schools, a blue-coat school, &c. Here, too, are a mechanics' institute, subscription library, news-room, hospital, and dispensary. Ripon was once famous for the manufacture of spurs and of woollen fabrics. Many saddletrees are made here; tanning, malting, and linen-weaving are also carried on. Near the town the Ure is crossed by a fine bridge. A short canal, constructed in 1767, brings the navigation up to the town. A weekly market and six annual fairs are held, chiefly for cattle, leather, and cloth. The borough is governed by a mayor, three other aldermen, and twelve councillors; and it sends two members to the House of Commons. It is a place of much antiquity, having existed in the time of the Saxons, who were here defeated by the Danes at an early period. A monastery was founded in 661, when there were only thirty houses in the place; and the town was made a borough by Alfred the Great. In 1069 it was wasted by William the Conqueror, and in 1319 and 1324 by the Scots under Bruce. In 1643 it was seized by the parliamentary party, but rescued for the royalists by Sir John Mollory. Pop. (1851) of the parish, 15,103; of the parliamentary borough, 6080.

RIPPERDA, JOHN WILLIAM, *Baron of*, a political adventurer, was born in the province of Gröningen in the Netherlands, in 1680, and was educated in the college of the Jesuits at Cologne. A desire for power began early to be seen in his actions. He married a rich wife that he might not be hampered by poverty in the race of ambition. He assumed the creed of a Protestant to make himself eligible for government offices. A colonelcy in the army did not content him. He did not cease to show off his accomplishments until, in 1715, he was appointed ambassador to Spain. Ripperda had not been very long at the

Ritson.

intriguing chance-directed court of Madrid before he resolved to try his hand in the game of Spanish politics. Laying down the office of Dutch ambassador in 1718, he brought all his arts into play. He secured the interest of the influential Jesuits by becoming a pious and penitent convert to the Catholic faith. He made his talents known to the king, Philip V., by drawing up schemes for the renovation of the national prosperity. Nor did his ambition hesitate to try more dangerous artifices. Returning from an embassy to Vienna in 1725, he pretended to the queen that he had effected her favourite scheme of betrothing her son Don Carlos to the eldest archduchess. His immediate elevation to a dukedom, and to the office of prime minister, compelled him to persist in this imposture. Lie was backed up by lie; the nation was impoverished to furnish him with hush-money; and he continued to try every bungling shift until, in 1726, he was convicted and disgraced. The rest of Ripperda's life was spent in a fruitless attempt to retrieve his fortune. Escaping from the castle of Segovia, he sought in vain for a place of political importance in some foreign country. The English statesmen treated him hospitably only so long as they were at variance with Spain. He could not see the slightest chance of success at any other European court. It is true that at length the land of promise seemed to have been discovered in Morocco. He was welcomed thither by the Emperor Muley Abdallah, and after qualifying himself for office by becoming a Mohammedan, was placed at the head of the administration of the country. But his ambition soon began again to be thwarted. His royal patron was driven from the throne. He himself was glad to escape with his head to Tetuan. There he could find no better employment for his restless spirit than that of asserting himself to be the last and greatest of the prophets. He died in 1737, giving out as his new creed a heterogeneous mass of Mohammedan, Jewish, and Christian doctrines. (See *Lives of Alberoni, Ripperda, and Pombal*, by George Moore, London, 1819.)

RITSON, JOSEPH, a meritorious critic and antiquary, was born at Stockton-upon-Tees on the 2d October 1752. His family, whose original name seems to have been *Richardson*, were respectable yeomen in Westmoreland, and could trace their descent as far back as the reign of Edward VI. He received a solid education from the Rev. John Thompson, the incumbent of his native town, was articled first to a solicitor, and subsequently to a barrister, previous to his setting out for London. His earliest literary effort, which possesses very little merit, was an address to the ladies of Stockton, printed in the *Newcastle Miscellany* in 1772. Ritson had now reached his nineteenth year, and his personal eccentricities had already begun to develop themselves in ways which spoke more for the determination of the future critic than for his eminent personal courtesy. He then began the practice, to which he adhered through life, of restricting himself to a milk and vegetable diet. His biographer, Sir Harris Nicolas, informs us that Ritson made this resolution from "a most refined sense of humanity." Unfortunately, the future conduct of the acrimonious critic rather clouds this pretty motive; and however sentimental may have been the origin of the practice, its continuance must be attributed, "during the whole course of those thirty years," to a quite different cause. As illustrative of Ritson's character, however, it throws much light on that determination, which occasionally approached something like doggedness, to judge on every subject for himself. In 1773 he visited Edinburgh on a short holiday excursion, and so much had he already been smitten with the antiquarian fever that he finds, on summing up his purchases of "tartans" and other items, that there was "not money left to pay my reckoning," at which he expresses great distress. In 1775 Ritson settled in London as a conveyancer, at a salary of L.150. He seems to have

Ritson.

lost both his parents during these years, to whom he was very much attached. In 1778 he printed a broadside entitled *Tables showing the Descent of the Crown of England*, which displayed accuracy and research, and proved the writer to be a firm Jacobite. He visited Oxford in 1779 to explore the literary treasures of the Bodleian; and his diary during this journey affords the first evidence of his sceptical opinions. He printed anonymously, in 1781, a small satirical tract termed *The Stockton Jubilee, or Shakspeare in his Glory*; in 1782 he visited Cambridge, and made the acquaintance of Dr Farmer, whom he describes as "a most sensible, liberal, benevolent, and worthy man." He was busily occupied at this time with his "scurrilous libel upon Warton," as he jocularly called his *Observations on the History of English Poetry*. The rude and bold style of this work, the severity of its criticisms, and the reckless personal taunts in which the writer indulged, brought down upon him a perfect horde of enemies, from whom his erudition, research, and candour served in vain to shield him. In vain it was that Ritson disclaimed all personal motives, that he averred he had no other object but truth and justice; he had been guilty of coarse and intemperate treatment of a highly respectable man, and such an offence could not be tolerated. A controversy accordingly raged in the *Gentleman's Magazine*, in which the formidable critic played of course a very important part. It may not be unworthy of remark that a late editor of Warton's *History of English Poetry* adopted the greater part of Ritson's observations. In 1783 he published a volume of *Remarks, Critical and Illustrative, on the Text of the last edition of Shakspeare*, in which he fell foul of Johnson and Stevens in a very unceremonious manner for the very careless way in which they had gone about their task. Despite, however, the acerbity of the writer, the public had much reason to thank him for his profound research, his felicitous conjectures, and his singular acquaintance with the great poet. This year was one of the most prolific of Ritson's pen. Besides editing *Gammer Gurton's Garland, or the Nursery Parnassus*, he published a *Select Collection of English Songs*, in 3 vols., to which he prefixed a historical essay of very great merit. In 1784 he published a slight tract called the *Bishopric Garland, or Durham Minstrel*; and about the same period was appointed high bailiff of the Liberty of the Savoy. The ensuing four years he seems to have devoted to his profession. There is one work from his pen during this period, entitled the *Spartan Manual, or Tablet of Morality*, for "the improvement of youth, and the promoting of wisdom and virtue." His *Quip Modest* was published during the same year, which was the letting out of a deadly feud between the author and the *Critical Review*. In 1790 appeared Ritson's *Ancient Songs*, and the succeeding year witnessed the publication of his *Pieces of Ancient Popular Poetry*, in an unusual style of typographical elegance. During the same year he visited Paris, and the ancient Jacobite found himself called upon to venerate the new order of things in the French metropolis; and he went so far as to adopt the French calendar in dating, and the republican style in closing his letters to his "citizen" friends. His nervous system was gradually giving way; and he could only write, he tells us, with great difficulty. Yet his labour must have been incessant. Between the years 1793 and 1795 appeared his *English Anthology*, his *Scottish Songs*, his *Poems of Laurence Minot* written in 1352, and his celebrated *Collection of the Robin Hood Ballads*. After a short respite, his pen was again busy; and in 1803 he brought out his *Bibliographia Poetica*, being a catalogue of English poets between the twelfth and the sixteenth centuries; a *Collection of English Metrical Romances*; and, as his final effort, *An Essay on Abstinence from Animal Food as a Moral Duty*. Of the numerous literary

friends of Ritson, one of the most genial was Sir Walter Scott, who alludes to him frequently in his poems and novels in terms of kindness and respect. But the busy strife of men was already waxing fainter and fainter on his ear, more dimly shone to him the pleasant sunlight, and tangible things were gradually becoming more and more intangible, when a great summons came on the 23d of September 1803. He left a number of works all but ready for the press, which have since appeared under the care of his nephew. They are, *The Life of King Arthur; Memoirs of the Celts and Gauls; Annals of the Caledonians; Fairy Tales*. (See the *Letters* of Joseph Ritson, Esq., with a memoir of the author, by Sir Harris Nicolas, 2 vols. 1833.)

RITTENHOUSE, DAVID, an eminent American astronomer, was born near Germantown in Pennsylvania in 1732, and was early put to work on his father's farm. His youth was characterised by signs of uncommon talent. Every spare moment was employed in gratifying his taste for the exact sciences. When he stopped his team on the field, he covered the plough-tails with mathematical figures. As he sauntered about in the evening after his day's labour, he plied his knife in making wooden clocks. A present of watchmaking tools, which he received at the age of eighteen, was the means of still further developing his genius. Taking up the more congenial trade of a watchmaker, he enjoyed greater opportunities for prosecuting his favourite studies. The utmost use was made of the two or three mathematical books which he had. Ere he was twenty he had begun to read the *Principia*. It is even said that he had found out the method of fluxions before he was aware of the discoveries of Newton and Leibnitz on the same subject. The attainments of Rittenhouse soon came to be generally acknowledged, and a series of honours and appointments followed. In 1769 he was named one of the committee to observe the transit of Venus over the sun's disk. In 1779 he was employed to determine the boundary line between Pennsylvania and Virginia. The Academy of Arts and Sciences at Boston elected him a member in 1782. The American Philosophical Society made him their president, in the room of Franklin, in 1791. The Royal Society of London also elected him a fellow in 1795. He was director of the mint of the United States when he was seized with his last attack of debility in 1795; and he died in June 1796. His published works consist of a number of papers, chiefly on astronomical subjects, in the *Transactions of the American Philosophical Society*.

RIVA (Germ. *Reif*), a town of the Tyrol, in the circle and 9 miles W.S.W. of Roveredo, stands in a beautiful situation at the head of the Lake of Garda, under the lofty and precipitous mountains which impart grandeur to the scenery of the lake. The climate is delicious; vines, myrtles, oranges, and olives grow in the open air; but the town is dirty and dilapidated. The castle of La Rocca, now a prison, and several convents, are the chief buildings. The lake abounds in fish; and the port is much frequented. Pop. 4980.

RIVE-DE-GIER, a town of France, in the department of Loire, on the right bank of the Gier, 12 miles N.E. of St Etienne. It is entirely a modern town, having nearly trebled its population since 1815; and it derives its importance and prosperity from the coal-fields among which it is situated. Formerly it had fortifications, but these have been destroyed. There are no public buildings of any importance. The river was once crossed by an ancient Roman bridge which has been removed, and its place supplied by five of modern erection. There are more than forty coal-mines in operation in the vicinity worked by steam. Lyons and many other towns derive their supply of fuel, in whole or in part, from Rive-de-Gier. It has large glass-works, and manufactories of steel, hardware, machinery, silk, &c. The trade is very considerable; and the canal of Givors connects the place with Givors on the Rhone. Pop. 11,694.

RIVER.¹

River.	A RIVER is a current of fresh water, flowing in a BED or CHANNEL from its source to the sea.	River.	
Definition.	The term is appropriated to a <i>considerable</i> collection of waters, formed by the conflux of two or more BROOKS, which deliver into its channel the united streams of several RIVULETS, which have collected the supplies of many RILLS trickling down from numberless springs, and the torrents which carry off from the sloping grounds the surplus of every shower.	and becomes the support and ornament of the country. Now increased by numerous alliances, and advanced in its course of existence, it becomes grave and stately in its motions, loves peace and quiet; and in majestic silence rolls on its mighty waters, till it is laid to rest in the vast abyss.	
Utility of rivers.	Rivers form one of the chief features of the surface of this globe, serving as voiders of all that is immediately redundant in our rains and springs, and also as boundaries and barriers, and even as highways, and in many countries as plentiful storehouses. They also fertilize our soil by laying upon our warm fields the richest mould, brought from the high mountains, where it would have remained useless for want of genial heat.	The philosopher, the real lover of wisdom, sees much to admire in the economy and mechanism of running waters; and there are few operations of nature which give him more opportunities of remarking the nice adjustment of the most simple means for attaining many purposes of most extensive beneficence. All mankind seems to have felt this. The heart of man is ever open (unless perverted by the habits of selfish indulgence and arrogant self-conceit) to impressions of gratitude and love. He who ascribes the religious principle (debased though it be by the humbling abuses of superstition) to the workings of fear alone, may betray the slavish meanness of his own mind, but gives a very unfair and a false picture of the hearts of his neighbours. Lucretius was but half a philosopher when he penned his often quoted apophthegm. Indeed his own invocation shows how much the animal was blended with the sage.	The religious respect for rivers.
Origin of their names.	Being such interesting objects of attention, every branch acquires a proper name, and the whole acquires a sort of personal identity, of which it is frequently difficult to find the principle; for the name of the great body of waters which discharges itself into the sea is traced backwards to one of the sources, while all the contributing streams are lost, although their waters form the chief part of the collection. And sometimes the feeder in which the name is preserved is smaller than others which are united to the current, and which like a rich but ignoble alliance lose their name in that of the more illustrious family. Some rivers indeed are respectable even at their birth, coming at once in force from some great lake. Such is the Rio de la Plata, the river St Lawrence, and the mighty streams which issue in all directions from the Baical Lake. But, like the sons of Adam, they are all of equal descent, and should take their name from one of the feeders of these lakes. This is indeed the case with a few, such as the Rhone, the Rhine, the Nile. These, after having mixed their waters with those of the lake, resume their appearance and their name at its outlet.	We apprehend, that whoever will read with an honest and candid mind, unbiassed by licentious wishes, the accounts of the ancient superstitions, will acknowledge that the amiable emotions of the human soul have had their share in creating the numerous divinities whose worship filled up their calendars. The sun and the host of heaven have in all ages and nations been the objects of a sincere worship. Next to them, the rivers seem to have attracted the grateful acknowledgments of the inhabitants of the adjacent countries. They have everywhere been considered as a sort of tutelar divinities; and each little district, every retired valley, had its river-god, who was preferred to all others with a partial fondness. The expostulation of Naaman the Syrian, who was offended with the prophet for enjoining him to wash in the river Jordan, was the natural effusion of this attachment. "What!" said he, "are not Abana and Pharpar, rivers of Damascus, more excellent than all the waters of Judea? Might I not wash in them and be clean? So he went away wroth."	The effect of gratitude and affection.
Origin and progress similar to the life of man.	But in general their origin and progress, and even the features of their character, bear some resemblance (as has been prettily observed by Pliny) to the life of man. The river springs from the earth, but its origin is in heaven. Its beginnings are insignificant, and its infancy is frivolous; it plays among the flowers of a meadow; it waters a garden, or turns a little mill. Gathering strength in its youth, it becomes wild and impetuous. Impatient of the restraints which it still meets with in the hollows among the mountains, it is restless and fretful; quick in its turnings, and unsteady in its course. Now it is a roaring cataract, tearing up and overturning whatever opposes its progress, and it shoots headlong down from a rock; then it becomes a sulken and gloomy pool, buried in the bottom of a glen. Recovering breath by repose, it again dashes along, till, tired of the uproar and mischief, it quits all that it has swept along, and leaves the opening of the valley strewn with the rejected waste. Now, quitting its retirement, it comes abroad into the world, journeying with more prudence and discretion, through cultivated fields, yielding to circumstances, and winding round what would trouble it to overwhelm or remove. It passes through the populous cities and all the	In those countries particularly, where the rural labours and the hopes of the shepherd and the husbandman were not so immediately connected with the approach and recess of the sun, and depended rather on what happened in a far distant country by the falls of periodical rains or the melting of collected snows, the Nile, the Ganges, the Indus, the river of Pegu, were the sensible agents of nature in procuring to the inhabitants of their fertile banks all their abundance, and they became the objects of grateful veneration. Their sources were sought out with anxious care even by conquering princes; and when found, were universally worshipped with the most affectionate devotion. These remarkable rivers, so eminently and so palpably beneficent, preserve to this day, amidst every change of habit, and every increase of civilization and improvement, the fond adoration of the inhabitants of those fruitful countries through which they hold their stately course, and their waters are still held sacred. No progress of artificial refinement, not all the corruption of luxurious sensuality, has	

¹ From the great ability displayed in this article by the late Professor Robison of Edinburgh, and from the frequent allusion to it, even at the present day, by men of the first distinction in physical science, the Editor has been induced to allow it a place here. (For further information, see HYDRODYNAMICS and the SIXTH DISSERTATION.)

History. been able to eradicate this plant of native growth from the heart of man. The sentiment is congenial to his nature, and therefore it is universal; and we could almost appeal to the feelings of every reader, whether he does not perceive it in his own breast. Perhaps we may be mistaken in our opinion in the case of the corrupted inhabitants of the populous and busy cities, who are habituated to the fond contemplation of their own individual exertions as the sources of all their hopes. Give the shoemaker but leather and a few tools, and he defies the powers of nature to disappoint him; but the simpler inhabitants of the country, the most worthy and the most respectable part of every nation, after equal, perhaps greater exertion, both of skill and of industry, are more accustomed to resign themselves to the great ministers of Providence, and to look up to heaven for the "early and the latter rains," without which all their labours are fruitless.

Extrema per illos
Numenque excedens terris vestigia fecit.

And among the husbandmen and the shepherds of all nations and ages, we find the same fond attachment to their springs and rivulets.

Fortunate senex, hic, inter flumina nota
Et fontes sacros, frigus captabis opacum,

was the mournful ejaculation of poor Melibæus. We hardly know a river of any note in our own country whose source is not looked on with some respect.

We repeat our assertion, that this worship was the offspring of affection and gratitude, and that it is giving a very unfair and false picture of the human mind to ascribe these superstitions to the working of fear alone. These would have represented the river-gods as seated on ruins, brandishing rooted-up trees, with angry looks, pouring out their sweeping torrents. But no such thing. The lively imagination of the Greeks felt, and expressed with an energy unknown to all other nations, every emotion of the human soul. They figured the Naiads as beautiful nymphs, patterns of gentleness and of elegance. These they represented as partially attached to the children of men; and their interference in human affairs is always in acts of kind assistance and protection. They resemble, in this respect, the rural deities of the northern nations, the fairies, but without their caprices and resentments. And if we attend to the descriptions and representations of their RIVER-GODS, beings armed with power, an attribute which slavish fear never fails to couple with cruelty and vengeance, we shall find the same expression of affectionate trust and confidence in their kind dispositions. They are generally called by the respectable but endearing name of *father*. "Da Tyberi pater," says Virgil. Mr Bruce says that the Nile at its source is called the *abay*, or "father." We observe this word, or its radix, blended with many names of rivers of the east; and think it probable that when our traveller got this name from the inhabitants of the neighbourhood, they applied to the stream what is meant to express the tutelar or presiding spirit. The river-gods are always represented as venerable old men, to indicate their being coeval with the world. But it is always a *cruda viridisque senectus*, and they are never represented as oppressed with age and decrepitude. Their beards are long and flowing, their looks placid, their attitude easy, reclined on a bank, covered, as they are crowned, with never-fading sedges and bulrushes, and leaning on their urns, from which they pour out their plentiful and fertilizing streams. Mr Bruce's description of the sources of the Nile, and of the respect paid to the sacred waters, has not a frowning feature; and the hospitable old man, with his fair daughter Irepone, and the gentle priesthood which peopled the little village of Geesh, form a contrast with the neighbouring Galla (among whom a mili-

tary leader was called the *lamb*, because he did not murder pregnant women), which very clearly paints the inspiring principle of this superstition. Pliny says (lib. viii. 8) that at the source of the Clitumnus there is an ancient temple highly respected. The presence and the power of the divinity are expressed by the fates which stand in the vestibule. Around this temple are several little chapels, each of which covers a sacred fountain; for the Clitumnus is the father of several little rivers which unite their streams with him. At some distance below the temple is a bridge which divides the sacred waters from those which are open to common use. No one must presume to set his foot in the streams above this bridge; and to step over any of them is an indignity which renders a person infamous. They can only be visited in a consecrated boat. Below the bridge we are permitted to bathe, and the place is incessantly occupied by the neighbouring villagers. See also Vibius Sequester Oberlini, p. 101-103, and 221-223; also Sueton. *Caligula*, c. 43; Virg. *Georg.* ii. 146.

What is the cause of all this? The Clitumnus, near its source, flows through the richest pastures, through which it was carefully distributed by numberless drains; and these nourished cattle of such spotless whiteness and extraordinary beauty that they were sought for with eagerness over all Italy, as the most acceptable victims in their sacrifices. Is not this superstition then an effusion of gratitude?

Such are the dictates of kind-hearted nature in our breasts, before it has been vitiated by vanity and self-conceit, and we should not be ashamed of feeling the impression. We hardly think of making any apology for dwelling a little on this incidental circumstance of the superstitious veneration paid to rivers. We cannot think that our readers will be displeased at having agreeable ideas excited in their minds, being always of opinion that the torch of true philosophy will not only enlighten the understanding, but also warm and cherish the affections of the heart.

With respect to the origin of rivers, we have very little to offer in this place. It is obvious to every person, that besides the torrents which carry down into the rivers what part of the rains and melted snows is not absorbed by the soil or taken up by the plants which cover the earth, they are fed either immediately or remotely by the springs. A few remarkable streams rush at once out of the earth in force, and must be considered as the continuation of subterraneous rivers, whose origin we are therefore to seek out; and we do not know any circumstance in which their first beginnings differ from those of other rivers, which are formed by the union of little streams and rills, each of which has its own source in a spring or fountain. This question, therefore, what is the process of nature, and what are the supplies which fill our springs? will be treated of under the word SPRING.

Whatever be the source of rivers, it is to be met with in almost every part of the globe. The crust of earth with which the rocky framing of this globe is covered is generally stratified. Some of these strata are extremely pervious to water, having but small attraction for its particles, and being very porous. Such is the quality of gravelly strata in an eminent degree. Other strata are much more firm, or attract water more strongly, and refuse it passage. This is the case with firm rock and with clay. When a stratum of the first kind has one of the other immediately under it, the water remains in the upper stratum, and bursts out wherever the sloping sides of the hills cut off the strata, and this will be the form of a trickling spring, because the water in the porous stratum is greatly obstructed in its passage towards the outlet. As this irregular formation of the earth is very general, we must have springs, and of course rivers or rivulets, in every corner where there are high grounds.

Rivers flow from the higher to the low grounds. It is

History.

History. the arrangement of this elevation which distributes them over the surface of the earth. This appears to be accomplished with considerable regularity; and, except the great desert of Kobi on the confines of Chinese Tartary, we do not remember any very extensive tract of ground that is deprived of those channels for voiding the superfluous waters; and even there they are far from being redundant.

Course of the rivers of Europe. The courses of rivers give us the best general method for judging of the elevation of a country. Thus it appears that Savoy and Switzerland are the highest grounds of Europe, from whence the ground slopes in every direction. From the Alps proceed the Danube and the Rhine, whose courses mark the two great valleys, into which many lateral streams descend. The Po also and the Rhone come from the same head, and with a steeper and shorter course find their way to the sea through valleys of less breadth and length. On the west side of the valleys of the Rhine and the Rhone the ground rises pretty fast, so that few tributary streams come into them from that side; and from this gentle elevation France slopes to the westward. If a line, nearly straight, but bending a little to the northward, be drawn from the head of Savoy and Switzerland all the way to Solikamskoy in Siberia, it will nearly pass through the most elevated part of Europe; for in this tract most of the rivers have their rise. On the left go off the various feeders of the Elbe, the Oder, the Wesel, the Niemen, the Duna, the Neva, the Dwina, the Petzora. On the right, after passing the feeders of the Danube, we see the sources of the Sereth and Pruth, the Dniester, the Bog, the Dnieper, the Don, and the mighty Volga. The elevation, however, is extremely moderate; and it appears from the levels taken with the barometer by the Abbé Chappe d'Auteroche, that the head of the Volga is not more than 470 feet above the surface of the ocean. And we may observe here, by the by, that its mouth, where it discharges its waters into the Caspian Sea, is undoubtedly lower by many feet than the surface of the ocean. (See PNEUMATICS.) Spain and Finland, with Lapland, Norway, and Sweden, form two detached parts, which have little symmetry with the rest of Europe.

of Asia. A chain of mountains begins in Nova Zembla, and stretches due south to near the Caspian Sea, dividing Europe from Asia. About three or four degrees north of the Caspian Sea it bends to the south-east, traverses Western Tartary, and passing between the Tengis and Zaizan lakes, it then branches to the east and south. The eastern branch runs to the shores of Korea and Kamtschatka. The southern branch traverses Turkestan and Thibet, separating them from India, and at the head of the kingdom of Ava joins an arm stretching from the great eastern branch, and here forms the centre of a very singular radiation. Chains of mountains issue from it in every direction. Three or four of them keep very close together, dividing the continent into narrow slips, which have each a great river flowing in the middle, and reaching to the extreme points of Malacca, Cambodia, and Cochinchina. From the same central point proceeds another great ridge due east, and passes a little north of Canton in China. We called this a singular centre; for though it sends off so many branches, it is by no means the most elevated part of the continent. In the triangle which is included between the first southern ridge (which comes from between the lakes Tengis and Zaizan), the great eastern ridge, and its branch which almost unites with the southern ridge, lie the Boutan and part of Thibet; and the many little rivers which occupy its surface flow southward and eastward, uniting a little to the north of the centre often mentioned, and then pass through a gorge eastward into China. The higher grounds (if we except the ridges of mountains which are boundaries) of the continent seem to be in the country of the Calmucs, about 96° east from London, and latitude 43° or 45° north. It is

History. represented as a fine though sandy country, having many little rivers which lose themselves in the sand, or end in little salt lakes. This elevation stretches north-east to a great distance; and in this tract we find the heads of the Irtysh, Selenga, and Tunguskaia (the great feeders of the Oby), the Olenitz, the Lena, the Yana, and some other rivers, which all go off to the north. On the other side we have the great river Amur, and many smaller rivers, whose names are not familiar. The Hoangho, the great river of China, rises on the south side of the great eastern ridge we have so often mentioned. This elevation, which is a continuation of the former, is somewhat of the same complexion, being very sandy, and at present is a desert of prodigious extent. A great ridge of mountains begins at the south-east corner of the Euxine Sea, and proceeds eastward, ranging along the south side of the Caspian, and, still advancing, unites with the mountains first mentioned in Thibet, sending off some branches to the south, which divide Persia, India, and Thibet. From the south side of this ridge flow the Euphrates, Tigris, Indus, and Ganges, and from the north the ancient Oxus and many unknown streams.

Of the rivers of Africa we still know but little. The Nile indeed is perhaps better known than any river out of Europe; and of it, so far as yet known, we have given a full account in a separate article. (See NILE.)

By the register of the weather kept by Mr Bruce at Gondar in 1770 and 1771, it appears that the greatest rains fall about the beginning of July. He says that at an average each month after June it doubles its rains. The calish or canal is opened at Cairo about the 9th of August, when the river has risen fourteen peeks (each twenty-one inches), and the waters begin to decrease about the 10th of September. Hence we may form a conjecture concerning the time which the latter employs in coming from Abyssinia. Mr Bruce supposes it nine days, which would require a velocity of not less than fourteen feet in a second; a thing past belief, and inconsistent with all our notions. The general slope of the river is greatly diminished by several great cataracts; and Mr Bruce expressly says that he might have come down from Sennaar to the cataracts of Syene in a boat, and that it is navigable for boats far above Sennaar. He came from Syene to Cairo by water. We apprehend that no boat would venture down a stream moving even six feet in a second, and none could row up if the velocity was three feet. As the waters begin to decrease about the 10th of September, we must conclude that the water then flowing past Cairo had left Abyssinia when the rains had greatly abated. Judging in this way, we must still allow the stream a velocity of more than six feet. Had the first swell at Cairo been noticed in 1770 or 1771, we might have guessed better. The year that Thevenot was in Egypt, the first swell of eight peeks was observed on the 28th of January. The calish was opened for fourteen peeks on the 14th of August, and the waters began to decrease on the 23d of September, having risen to twenty-one and two-third peeks. We may suppose a similar progress at Cairo corresponding to Mr Bruce's observations at Gondar, and date every thing five days earlier.

The frame-work (so to call it) of America is better known, and is singular.

A chain of mountains begins, or at least is found, in longitude 110° west of London, and latitude 40° north, on the northern confines of the kingdom of Mexico, and, stretching southward through that kingdom, forms the ridge of the neck of land which separates North from South America, and keeping almost close to the shore, ranges along the whole western coast of South America, terminating at Cape Horn. In its course it sends off branches, which after separating from it for a few leagues, rejoin it again, enclosing valleys of great extent from north to south, and of prodigious

History. gious elevation. In one of these, under the equatorial sun, stands the city of Quito, in the midst of extensive fields of barley, oats, wheat, and gardens containing apples, pears, and gooseberries, and, in short, all the grains and fruits of the cooler parts of Europe; and although the vine is also there in perfection, the olive is wanting. Not a dozen miles from it, in the low countries, the sugar-cane, the indigo, and all the fruits of the torrid zone, find their congenial heat, and the inhabitants swelter under a burning sun. At a small distance on the other hand tower aloft the pinnacles of Pichincha, Corambourou, and Chimborazo, crowned with never-melting snows.

The individual mountains of this stupendous range cut off therefore all communication between the Pacific Ocean and the inland continent; and no rivers are to be found on the west coast of South America which have any considerable length of course or body of waters. The country is drained, like Africa, in the opposite direction. Not 100 miles from the city of Lima, the capital of Peru, which lies almost on the sea-shore, and just at the foot of the high Cordilleras, arises out of a small lake the Maragnon or Amazons river, which, after running northward for about 100 miles, takes an easterly direction, and crosses nearly the broadest part of South America, and falls into the great western ocean at Para, after a course of not less than 4095 miles. In the first half of its descent it receives a few middle-sized rivers from the north, and from the south it receives the great river Combos, springing from another little lake not fifty miles distant from the head of the Maragnon, and enclosing between them a wide extent of country. It then receives the Yuta, the Yuerva, the Cuchivara, and Parana Mire, each of which is equal to the Rhine; and then the Madeira, which has flowed above 1300 miles. At their junction the breadth is so great that neither shore can be seen by a person standing up in a canoe; so that the united stream must be about six miles broad. In this form it rolls along through a flat country, covered with impenetrable forests, and most of it as yet untrodden by human feet. Mr Condamine, who came down the stream, says that all is silent as the desert, and the wild beasts and numberless birds crowd round the boat, eyeing it as some animal of which they did not seem afraid. The bed was cut deep through an equal and yielding soil, which seemed rich in every part, if he could judge by the vegetation, which was rank in the extreme. What an addition to the possible population of this globe! A narrow slip along each bank of this mighty river would equal in surface the whole of Europe, and would probably exceed it in general fertility; and although the velocity in the main stream was considerable, he observed that it was extremely moderate, nay almost still, at the sides; so that in those parts where the country was inhabited, the Indians paddled up the river with perfect ease. Boats could go from Para to near the mouth of the Madeira in thirty-eight days, which is nearly 1200 miles.

Not far from the head of the Maragnon, the Cordilleras send off a branch to the north-east, which reaches and ranges along the shore of the Mexican Gulf; and the Rio Grande de Sta Martha occupies the angle between the ridges.

Another ridge ranges with interruption along the east coast of Terra Firma, so that the whole waters of this country are collected into the Oroonoko. In like manner, the north and east of Brazil are hemmed in by mountainous ridges, through which there is no considerable passage; and the ground sloping backwards, all the waters of this immense tract are collected from both sides by many considerable rivers into the great river Paraguay, or Rio de la Plata, which runs down the middle of the country for more than 1400 miles, and falls into the sea through a vast mouth, in latitude 35°.

Thus the whole of South America seems as if it had been formerly surrounded by a mound, and been a great basin. The ground in the middle, where the Parana, the Madeira, and the Plata, take their rise, is an immense marsh, uninhabitable on account of its exhalations, and quite impervious in its present state.

The manner in which the continent of North America is watered, or rather drained, has also some peculiarities. By looking at the map, one will observe, first of all, a general division of the whole of the best-known part into two, by the valleys in which the beds of the rivers St Lawrence and Mississippi are situated. The head of this is occupied by a singular series of fresh-water seas or lakes, viz. the Lakes Superior and Michigan, which empty themselves into Lake Huron by two cataracts. This again runs into Lake Erie by the river Detroit, and the Erie pours its water into the Ontario by the famous Fall of Niagara, and from the Ontario proceeds the great river St Lawrence.

The ground to the south-west of the Lakes Superior and Erie is somewhat lower, and the middle of the valley is occupied by the Mississippi and the Missouri, which receive on both sides a number of smaller streams, and, having joined, proceed to the south under the name Mississippi. In latitude 37° this river receives into its bed the Ohio, a river of equal magnitude, and the Cherokee river, which drains all the country lying at the back of the United States, separated from them by the ranges of the Appalachian Mountains. The Mississippi is now one of the chief rivers on the globe, and proceeds due south till it falls into the Mexican Bay through several shifting mouths, which greatly resemble those of the Danube and the Nile, having run above 1200 miles.

The elevated country between this bed of the Mississippi and St Lawrence and the Atlantic Ocean is drained on the east side by a great number of rivers, some of which are very considerable, and of long course; because instead of being nearly at right angles to the coast, as in other countries, they are in a great measure parallel to it. This is more remarkably the case with Hudson's river, the Delaware, Potomac, and Rappahannoc. Indeed the whole of North America seems to consist of ribs or beams laid nearly parallel to each other from north to south, and the rivers occupy the interstices. All those which empty themselves into the bay of Mexico are parallel and almost perfectly straight, unlike what are seen in other parts of the world. The westernmost of them all, the North river, as it is named by the Spaniards, is nearly as long as the Mississippi.

For the length of the courses, and some peculiarities of the principal rivers, see PHYSICAL GEOGRAPHY.

PART I.—THEORY OF THE MOTION OF RIVERS AND CANALS.

THE importance of this subject needs no commentary. Every nation, every country, every city is interested in it. Our wants, our comforts, and our pleasures require a knowledge of it. We must conduct the water of rivers to the centre of our dwellings; we must secure ourselves against their ravages; we must employ them to drive those machines which, by compensating for our personal weakness, make a few able to perform the work of thousands; we employ them to water and fertilize our fields, to decorate our mansions, to cleanse and embellish our cities, to preserve or extend our demesnes, to transport from county to county every thing which necessity, convenience, or luxury, has rendered precious to man: for these purposes we must confine and govern the mighty rivers, we must preserve or change the beds of the smaller streams, draw off from them what shall water our fields, drive our machines, or supply

History.

ance of the doctrine of the motion of rivers and canals.

Theory. our houses. We must keep up their waters for the purposes of navigation, or supply their places by canals; we must drain our fens, and defend them when drained; we must understand their motions, and their mode of secret, slow, but unceasing action, that our bridges, our wharfs, our dikes, may not become heaps of ruins. Ignorant how to proceed in these daily recurring cases, how often do we see projects of high expectation and heavy expense fail of their object, leaving the state burdened with works not only useless, but frequently hurtful?

This has long been a most interesting subject of study in Italy, where the fertility of their fields is not more indebted to their rich soil and happy climate, than to their numerous derivations from the rivers which traverse them; and in Holland and Flanders, where their very existence requires unceasing attention to the waters, which are every moment ready to swallow up the inhabitants, and where the inhabitants, having once subdued this formidable enemy, have made those very waters their indefatigable drudges, transporting through every corner of the country the materials of an extensive commerce.

Such having been our incessant occupations with moving waters, we should expect, that while the operative artists are continually furnishing facts and experiments, the man of speculative and scientific curiosity, excited by the importance of the subject, would ere now have made considerable progress in the science; and that the professional engineer would be daily acting from established principle, and be seldom disappointed in his expectations. Unfortunately, the reverse of this is nearly the true state of the case: each engineer is obliged to collect the greatest part of his knowledge from his own experience, and by many dear-bought lessons, to direct his future operations, in which he still proceeds with anxiety and hesitation; for we have not yet acquired principles of theory, and experiments have not yet been collected and published by which an empirical practice might be safely formed. Many experiments of inestimable value are daily made; but they remain with their authors, who seldom have either leisure, ability, or generosity, to add them to the public stock.

This science as yet in its infancy. The motion of waters has been really so little investigated as yet, that hydraulics may still be called a new study. We have merely skimmed over a few common notions concerning the motions of water; and the mathematicians of the first order seem to have contented themselves with such views as allowed them to entertain themselves with elegant applications of calculus. This, however, has not been their fault. They rarely had opportunity of doing more, for want of a knowledge of facts. They have made excellent use of the few which have been given them; but it required much labour, great variety of opportunity, and great expense, to learn the multiplicity of things which are combined even in the simplest cases of water in motion. These are seldom the lot of the mathematician; and he is without blame when he enjoys the pleasures within his reach, and cultivates the science of geometry in its most abstracted form. Here he makes a progress which is the boast of human reason, being almost insured from error by the intellectual simplicity of his subject. But when we turn our attention to material objects, and, without knowing either the size and shape of the elementary particles, or the laws which nature has prescribed for their action, presume to foresee their effects, calculate their exertions, direct their actions, what must be their consequence? Nature shows her independence with respect to our notions, and, always faithful to the laws which are enjoined, and of which we are ignorant, she never fails to thwart our views, to disconcert our projects, and render useless all our efforts.

To wish to know the nature of the elements is vain, and our gross organs are insufficient for the study. To sup-

pose what we do not know, and to fancy shapes and sizes at will, is to raise phantoms, and will produce a system, but will not prove a foundation for any science. But to interrogate Nature herself, study the laws which she so faithfully observes, catch her, as we say, in the fact, and thus wrest from her the secret; this is the only way to become her master, and it is the only procedure consistent with good sense. And we see that soon after Kepler detected the laws of the planetary motions, when Galileo discovered the uniform acceleration of gravity, when Paschal discovered the pressure of the atmosphere, and Newton discovered the laws of attraction and the track of a ray of light; astronomy, mechanics, hydrostatics, chemistry, optics, quickly became bodies of sound doctrine, and the deductions from their respective theories were found fair representations of the phenomena of nature. Whenever a man has discovered a law of nature, he has laid the foundation of a science, and he has given us a new mean of subjecting to our service some element hitherto independent; and so long as groups of natural operations follow a route which appears to us whimsical, and will not admit our calculations, we may be assured that we are ignorant of the principle which connects them all, and regulates their procedure.

This is remarkably the case with several phenomena in the motions of fluids, and particularly in the motion of water in a bed or conduit of any kind. Although the first general laws of Europe have for this century past turned much of their attention to this subject, we are almost ignorant of the *general laws* which may be observed in their motions. We have been able to select very few points of resemblance, and every case remains nearly an individual. About one hundred and fifty years ago we discovered, by experience only, the quantity and velocity of water issuing from a small orifice, and, after much labour, have extended this to any orifice; and this is almost the whole of our confidential knowledge. But as to the uniform course of the streams which water the face of the earth, and the maxims which will certainly regulate this agreeably to our wishes, we are in a manner totally ignorant. Who can pretend to say what is the velocity of a river of which you tell him the breadth, the depth, and the declivity? Who can say what swell will be produced in different parts of its course, if a dam or weir of given dimensions be made in it, or a bridge be thrown across it; or how much its waters will be raised by turning another stream into it, or sunk by taking off a branch to drive a mill? Who can say with confidence what must be the dimensions or slope of this branch, in order to furnish the water that is wanted, or the dimensions and slope of a canal which shall effectually drain a fenny district? Who can say what form will cause or will prevent the undermining of banks, the forming of elbows, the pooling of the bed, or the deposition of sands? Yet these are the most important questions.

The causes of this ignorance are the want or uncertainty of our principles; the falsity of our only theory, which is belied by experience; and the small number of proper observations or experiments, and difficulty of making such as shall be serviceable. We have, it is true, made a few experiments on the efflux of water from small orifices, and from them we have deduced a sort of theory, dependent on the fall of heavy bodies and the laws of hydrostatic pressure. Hydrostatics is indeed founded on very simple principles, which give a very good account of the laws of the quiescent equilibrium of fluids, in consequence of gravity and perfect fluidity. But by what train of reasoning can we connect these with the phenomena of the uniform motion of the waters of a river or open stream, which can derive its motion only from the slope of its surface, and the modifications of this motion or its velocity only from the width and depth of the stream? These are the only circumstances which can distinguish a portion of a river from

Theory.
Proper
mode of
investigation.

Theory. a vessel of the same size and shape, in which, however, the water is at rest. In both, gravity is the sole cause of pressure and motion; but there must be some circumstance peculiar to running waters which modifies the exertion of this active principle, and which, when discovered, must be the basis of hydraulics, and must oblige us to reject every theory founded on fancied hypothesis, and which can only lead to absurd conclusions; and surely absurd consequences, when legitimately drawn, are complete evidence of improper principles.

Principle on which the systems of hydraulics depend.

When it was discovered experimentally, that the velocities of water issuing from orifices at various depths under the surface were as the square roots of those depths, and the fact was verified by repeated experiments, this principle was immediately, and without modification, applied to every motion of water. Mariotte, Varignon, and Guglielmini, made it the basis of complete systems of hydraulics, which prevail to this day, after having received various amendments and modifications. The same reasoning obtains through them all, though frequently obscured by other circumstances, which are more perspicuously expressed by Guglielmini in his Fundamental Theorems.

He considers every point P (fig. 1) in a mass of fluid as an orifice in the side of a vessel, and conceives the particle as having a tendency to move with the same velocity with which it would issue from the orifice. Therefore, if a vertical line APC be drawn through that point, and if this be made the axis of a parabola ADE, or which A at the surface of the fluid is the vertex, and AB (four times the height through which a heavy body would fall in a second) is the parameter, the velocity of this particle will be represented by the ordinate PD of this parabola; that is, PD is the space which it would uniformly describe in a second.

Fig. 1.

Theory derived from running waters. From this principle is derived the following theory of it.

Let DC (fig. 2) be the horizontal bottom of a reservoir, to which is joined a sloping channel CK of uniform breadth, and let AB be the surface of the standing water in the reservoir.

Fig. 2.

Suppose the vertical plane BC pierced with an infinity of holes, through each of which the water issues. The velocity of each filament will be that which is acquired by falling from the surface AB.¹ The filament C, issuing with this velocity, will then glide down the inclined plane like any other heavy body; and (by the common doctrine of the motion down an inclined plane) when it has arrived at F, it will have the same velocity which it would have acquired by falling through the height OF, the point O being in the horizontal plane AB produced. The same may be said of its velocity when it arrives at H or K. The filament immediately above C will also issue with a velocity which is in the subduplicate ratio of its depth, and will then glide down above the first filament. The same may be affirmed of all the filaments, and of the superficial filament, which will occupy the surface of the descending stream.

From this account of the genesis of a running stream of water, we may fairly draw the following consequences.

1. The velocity of any particle R, in any part of the

stream, is that acquired by falling from the horizontal plane AN. **Theory.**

2. The velocity at the bottom of the stream is everywhere greater than anywhere above it, and is least of all at the surface.

3. The velocity of the stream increases continually as the stream recedes from its source.

4. The depths EF, GH, &c. in different parts of the stream, will be nearly in the inverse subduplicate ratio of the depths under the surface AN: for since the same quantity of water is running through every section EF and GH, and the channel is supposed of uniform breadth, the depth of each section must be inversely as the velocity of the water passing through it. This velocity is indeed different in different filaments of the section; but the mean velocity in each section is in the subduplicate ratio of the depth of the filament under the surface AB. Therefore the stream becomes more shallow as it recedes from the source; and in consequence of this the difference between LH and MG continually diminishes, and the velocities at the bottom and surface of the stream continually approach to equality, and at a great distance from the source they differ insensibly.

5. If the breadth of the stream be contracted in any part, the depth of the running water will be increased in that part, because the same quantity must still pass through; but the velocity at the bottom will remain the same, and that at the surface will be less than it was before; and the area of the section will be increased on the whole.

6. Should a sluice be put across the stream, dipping a little into the water, the water must immediately rise on the upper side of the sluice till it rises above the level of the reservoir; and the smallest immersion of the sluice will produce this effect. For, by lowering the sluice, the area of the section is diminished, and the velocity cannot be increased till the water heap up to a greater height than the surface of the reservoir; and this acquires a pressure which will produce a greater velocity of efflux through the orifice left below the sluice.

7. An additional quantity of water coming into this channel will increase the depth of the stream, and the quantity of water which it conveys; but it will not increase the velocity of the bottom filaments unless it comes from a higher source.

All these consequences are contrary to experience, and show the imperfection at least of the explanation. **These consequences**

The third consequence is of all the most contrary to experience. If any one will but take the trouble of following a single brook from its source to the sea, he will find it most rapid in its beginnings among the mountains, gradually slackening its pace as it winds among the hills and gentler declivities, and at last creeping slowly along through the flat grounds, till it is checked and brought to rest by the tides of the ocean.

Nor is the second consequence more agreeable to observation. It is universally found that the velocity of the surface in the middle of the stream is the greatest of all, and that it gradually diminishes from thence to the bottom and sides.

And the first consequence, if true, would render the running waters on the surface of this earth the instruments of immediate ruin and devastation. If the waters of our rivers, in the cultivated parts of a country, which are two, three, and four hundred feet lower than their sources, ran with the velocity due to that height, they would in a few minutes lay the earth bare to the very bones.

The velocities of our rivers, brooks, and rills, being so greatly inferior to what this theory assigns to them, the

The consequences drawn from this theory.

¹ See Guglielmini's Hydraulics, 21.

Theory. other consequences are equally contrary to experience. When a stream has its section diminished by narrowing the channel, the current increases in depth, and this is always accompanied by an increase of velocity through the whole of the section, and most of all at the surface; and the area of the section does not increase, but diminishes, all the phenomena thus contradicting in every circumstance the deduction from the theory; and when the section has been diminished by a sluice let down into the stream, the water gradually heaps up on the upper side of the sluice, and, by its pressure, produces an acceleration of the stream below the sluice, in the same way as if it were the beginning of a stream, as explained in the theory. The velocity now is composed of the velocity preserved from the source and the velocity produced by this subordinate accumulation; and this accumulation and velocity continually increase till they become such that the whole supply is again discharged through this contracted section: any additional water not only increases the quantity carried along the stream, but also increases the velocity, and therefore the section does not increase in the proportion of the quantity.

The theory, however, has been generally followed by the writers on the subject, It is surprising that a theory really founded on a conceit, and which in every one of the most familiar and obvious circumstances is contradicted by facts, should have met with so much attention. That Varignon should immediately catch at this notion of Guglielmini, and make it the subject of many elaborate analytical memoirs, is not to be wondered at. This author only wanted *donner prise au calcul*; and it was a usual joke among the academicians of Paris, when any new theorem was invented, *donnons le à Varignon à généraliser*. But his numerous theorems and corollaries were adopted by all, and still make the substance of the present systems of hydraulics. Gravesande, Muschenbroeck, and all the elementary treatises of natural philosophy, deliver no other doctrines; and Belidor, who has been considered as the first of all the scientific engineers, details the same theory in his great work the *Architecture Hydraulique*.

though some of the more ingenious saw its defects, and attempted to supply them. Guglielmini was, however, not altogether the dupe of his own ingenuity. He was not only a pretty good mathematician, but an assiduous and sagacious observer. He had applied his theory to some important cases which occurred in the exercise of his profession as inspector of the rivers and canals in the Milanese, and to the course of the Danube; and could not but perceive that great corrections were necessary for making the theory quadrate in some tolerable manner with observation; and he immediately saw that the motion was greatly obstructed by inequalities of the canal, which gave to the contiguous filaments of the stream transverse motions, which thwarted and confused the regular progress of the rest of the stream, and thus checked its general progress. These obstructions, he observed, were most effectual in the beginning of its course, while yet a small rill, running among stones, and in a very unequal bed. The whole stream being small, the inequalities bore a great proportion to it, and thus the general effect was great. He also saw that the same causes (these transverse motions produced by the unequal bottom) chiefly affect the contiguous filaments, and were the reasons why the velocity at the sides and bottom was so much diminished as to be less than the superficial velocity, and that even this might come to be diminished by the same cause. For he observed, that the general stream of a river is frequently composed of a sort of boiling or tumbling motion, by which masses of water are brought up to the surface and again descend. Every person must recollect such appearances in the freshes of a muddy river; and in this way Guglielmini was enabled to account in some measure for the disagreement of his theory with observation.

Mariotte had observed the same obstruction even in the smoothest glass pipes. Here it could not be ascribed to

Theory. the checks occasioned by transverse motions. He therefore ascribed it to friction, which he supposed to diminish the motion of fluid bodies in the same manner as of solids; and he thence concludes, that the filaments which immediately rub on the sides of the tube have their velocity gradually diminished, and that the filaments immediately adjoining to these, being thus obliged to pass over them or outstrip them, rub upon them and have their own velocity diminished in like manner, but in a smaller degree; and that the succeeding filaments towards the axis of the tube suffer similar but smaller diminutions. By this means the whole stream may come to have a smaller velocity; and at any rate, the medium velocity by which the quantity discharged is determined, is smaller than it would have been independent of friction.

Guglielmini adopted this opinion of Mariotte, and, in his next work on the Motion of Rivers, considered this as the chief cause of the retardation; and he added a third circumstance, which he considered as of no less consequence, the viscosity or tenacity of water. He observes that syrup, oil, and other fluids, where this viscosity is more remarkable, have their motions prodigiously retarded by it, and supposes that water differs from them only in the degree in which it possesses this quality; and he says, that by this means not only the particles which are moving more rapidly have their motions diminished by those in their neighbourhood which move slower, but that the filaments also which would have moved more slowly are accelerated by their more active neighbours, and that in this manner the superficial and inferior velocities are brought nearer to an equality. But this will never account for the universal fact that the superficial particles are the swiftest of all. The superficial particles, says he, acquire by this means a greater velocity than the parabolic law allows them; the medium velocity is often in the middle of the depth; the numerous obstacles continually multiplied and repeated, cause the current to lose the velocity acquired by the fall; the slope of the bottom then diminishes, and often becomes very small, so that the force remaining is hardly able to overcome the obstacles which are still repeated, and the river is reduced almost to a state of stagnation. He observes that the Rheno, a river of the Milanese, has near its mouth a slope of no more than 5', which he considers as quite inadequate to the task; and here he introduces another principle, which he considers as an essential part of the theory of open currents. This is, that there arises from the very depth of the stream a propelling force, which restores a part of the lost velocity. He offers nothing in proof of this principle, but uses it to account for and explain the motion of water in horizontal canals. The principle has been adopted by the numerous Italian writers on hydraulics, and, by various contrivances, interwoven with the parabolic theory, as it is called, of Guglielmini. Our readers may see it in various modifications in the *Idrostatica e Idraulica* of P. Lecchi, and in the *Sperienze Idrauliche* of Michelotti. It is by no means distinct either in its origin or in the manner of its application to the explanation of phenomena, and seems only to serve for giving something like consistency to the vague and obscure discussions which have been published on this subject in Italy. We have already remarked, that in that country the subject is particularly interesting, and has been much investigated. But the writers of England, France, and Germany, have not paid so much attention to it, and have more generally occupied themselves with the motion of water in close conduits, which seem to admit of a more precise application of mathematical reasoning.

Some of them have considered with more attention the effects of friction and viscosity. Sir Isaac Newton, with his usual penetration, had seen distinctly the manner in which it behoved these circumstances to operate. In his

Theory.

Newton's
observa-
tions on
this sub-
ject.

researches into the mechanism of the celestial motions, he had occasion to examine the famous hypothesis of Descartes, that the planets were carried round the sun by fluid vortices, and saw that there would be no end to uncertainty and dispute till the *modus operandi* of these vortices were mechanically considered. He therefore employed himself in the investigation of the manner in which the acknowledged powers of natural bodies, acting according to the received laws of mechanics, could produce and preserve these vortices, and restore that motion which was expended in carrying the planets round the sun. In the second book of the *Principles of Natural Philosophy*, he gives a series of beautiful propositions, viz. 51, 52, &c. with their corollaries, showing how the rotation of a cylinder or sphere round its axis in the midst of a fluid will excite a vortical motion in this fluid; and he ascertains with mathematical precision the motion of every filament of this vortex.

He sets out from the supposition that this motion is excited in the surrounding stratum of fluid in consequence of a want of perfect lubricity, and assumes as an hypothesis, that the initial resistance (or diminution of the motion of the cylinder) which arises from this want of lubricity, is proportional to the velocity with which the surface of the cylinder is separated from the contiguous surface of the surrounding fluid, and that the whole resistance is proportional to the velocity with which the parts of the fluid are mutually separated from each other. From this, and the equality of action and re-action, it evidently follows, that the velocity of any stratum of the vortex is the arithmetical medium between the velocities of the strata immediately within and without it. For the intermediate stratum cannot be in equilibrio, unless it is as much pressed forward by the superior motion of the stratum within it, as it is kept back by the slower motion of the stratum without it.

This beautiful investigation applies in the most perfect manner to every change produced in the motion of a fluid filament, in consequence of the viscosity and friction of the adjoining filaments; and a filament proceeding along a tube at some small distance from the sides has, in like manner, a velocity which is the medium between those of the filaments immediately surrounding it. It is therefore a problem of no very difficult solution to assign the law by which the velocity will gradually diminish as the filament recedes from the axis of a cylindrical tube. It is somewhat surprising that so neat a problem has never occupied the attention of the mathematicians during the time that these subjects were so assiduously studied; but so it is, that nothing precise has been published on the subject. The only approach to a discussion of this kind, is a Memoir of Mr Pitot, read to the academy of Paris in 1726, where he considers the velocity of efflux through a pipe. Here, by attending to the comparative superiority of the *quantity of motion* in large pipes, he affirms, that the total diminutions arising from friction will be (*cæteris paribus*) in the inverse ratio of the diameters. This was thankfully received by other writers, and is now a part of our hydraulic theories. It has not, however, been attended to by those who write on the motion of rivers, though it is evident that it is applicable to these with equal propriety; and had it been introduced, it would at once have solved all their difficulties, and particularly would have shown how an almost imperceptible declivity would produce the gentle motion of a great river, without having recourse to the unintelligible principle of Guglielmini.

Mr Couplet made some experiments on the motion of the water in the great main pipes of Versailles, in order to obtain some notions of the retardations occasioned by friction. They were found prodigious; but were so irregular, and unsuceptible of reduction to any general principle (and the experiments were indeed so few that they were unfit for this reduction), that he could establish no theory. What

Mr Belidor established on them, and makes a sort of system to direct future engineers, is quite unworthy of attention. Theory.

Upon the whole, this branch of hydraulics, although of much greater practical importance than the conduct of water in pipes, has never yet obtained more than a vague, and scarcely at all improved, attention from the mathematicians; and we ascribe it to their not having taken the pains to settle its first principles with the same precision as had been done in the other branch. They were, from the beginning, satisfied with a sort of applicability of mathematical principles, without ever making the application. Were it not that some would accuse us of national partiality, we would ascribe it to this, that Newton had not pointed out the way in this as in the other branch; for any intelligent reader of the performances on the motions of fluids in close vessels, will see that not a principle, nay hardly a step of investigation, has been added to those which were used or pointed out by Sir Isaac Newton. He has nowhere touched this question, the motion of water in an open canal. In his theories of the tides, and of the propagation of waves, he had an excellent opportunity for giving at once the fundamental principles of motion in a free fluid whose surface was not horizontal. But, by means of some of those happy and shrewd guesses, in which, as Daniel Bernoulli says, he excelled all men, he saw the undoubted consequences of some palpable phenomenon which would answer all his present purposes, and therefore entered no farther into the investigation.

The original theory of Guglielmini, or the principle adopted by him, that each particle of the vertical section of a running stream has a tendency to move as if it were issuing from an orifice at that depth under the surface, is false; and that it really does so in the face of a dam when the floodgate is taken away, is no less so; and if it did, the subsequent motions would hardly have any resemblance to those which he assigns them. Were this the case, the exterior form of the cascade would be something like what is sketched in fig. 3, with an abrupt angle at B, and a concave surface BEG. This will be evident to every one who combines the greater velocity of the lower filaments with the slower motion of those which must slide down above them. But this greater advance of the lower filaments cannot take place without an expenditure of the water under the surface AB. The surface therefore sinks, and B instantly ceases to retain its place in the horizontal plane. The water does not successively flow forward from A to B, and then tumble over the precipice; but immediately opening the floodgate, the water wastes from the space immediately behind it, and the whole puts on the form represented in fig. 4, consisting of the curve A b P c EG, convex from A to c, and concave from thence forward. The superficial water begins to accelerate all the way from A; and the particles may be supposed (for the present) to have acquired the velocity corresponding to their depth under the horizontal surface. This must be understood as nothing more than a vague sketch of the motions. It requires a very critical and intricate investigation to determine either the form of the upper curve or the motions of the different filaments. The place A, where the curvature begins, is of equally difficult determination, and is various according to the differences of depth and of inclination of the succeeding canal.

We have thus given an historical sketch of the progress

Fig. 3.

Fig. 4.

Theory. Uncertainty of the theories when applied to practice exemplified.

which had been made in this part of hydraulics, that our readers might form some opinion of the many dissertations which have been written on the motion of rivers, and of the state of the arts depending on it. Much of the business of the civil engineer is intimately connected with it; and we may therefore believe, that since there was so little principle in the theories, there could be but very little certainty in the practical operations. The fact has been, that no engineer could pretend to say, with any precision, what would be the effect of his operations. One whose business had given him many opportunities, and who had kept accurate and judicious registers of his own works, could pronounce, with some probability, how much water would be brought off by a drain of certain dimensions and a given slope, when the circumstances of the case happened to tally with some former work in which he had succeeded or failed; but out of the pale of his own experience he could only make a sagacious guess. A remarkable instance of this occurred some time ago. A small aqueduct was carried into Paris. It had been conducted on a plan presented to the academy, who had corrected it, and gave a report of what its performance would be. When executed in the most accurate manner, it was deficient in the proportion of five to nine. When the celebrated Desaguliers was employed by the city of Edinburgh to superintend the bringing in the water for the supply of the city, he gave a report on the plan which was to be followed. It was executed to his complete satisfaction; and the quantity of water delivered was about one sixth of the quantity which he promised, and about one eleventh of the quantity which the no less celebrated Maclaurin calculated from the same plan.

Necessity of multiplying experiments.

Such being the state of our theoretical knowledge (if it can be called by this name), naturalists began to be persuaded that it was but losing time to make use of a theory so incongruous with observation, and that the only safe method of proceeding was to multiply experiments in every variety of circumstances, and to make a series of experiments in every important case, which should comprehend all the practical modifications of that case. Perhaps circumstances of resemblance might occur, which would enable us to connect many of them together, and at last discover the principles which occasioned this connection; by which means a theory founded on science might be obtained. And if this point should not be gained, we might perhaps find a few general facts, which are modified in all these particular cases, in such a manner that we can still trace the general facts, and see the part of each particular case which depends on it. This would be the acquisition of what may be called an empirical theory, by which every phenomenon would be explained, in so far as the explanation of a phenomenon is nothing more than the pointing out the general fact or law under which it is comprehended; and this theory would answer every practical purpose, because we should confidently foresee what consequences would result from such and such premises; or if we should fail even in this, we should still have a series of experiments so comprehensive, that we could tell what place in the series would correspond to any particular case which might be proposed.

Labours of Michelotti and Bossut in this way. There are two gentlemen whose labours in this respect deserve very particular notice, Professor Michelotti of Turin, and the Abbé Bossut of Paris. The first made a prodigious number of experiments, both on the motion of water through pipes and in open canals. They were performed at the expense of the sovereign, and no expense was spared. A tower was built of the finest masonry, to serve as a vessel from which the water was to issue through holes of various sizes, under pressures of from five to twenty-two feet. The water was received into basins constructed of masonry and nicely lined with stucco, from whence it was conveyed in canals of brickwork lined with stucco, and of various forms and declivities. The experiments on the expense of

water through pipes are, of all that have yet been made, the most numerous and exact, and may be appealed to on every occasion. Those made in open canals are still more numerous, and are no doubt equally accurate; but they have not been so contrived as to be so extensively useful, being in general very unlike the important cases which will occur in practice; and they seem to have been contrived chiefly with the view of establishing or overturning certain points of hydraulic doctrine which were probably prevalent at the time among the practical hydraulists.

The experiments of Bossut are also of both kinds; and though on a much smaller scale than those of Michelotti, seem to deserve equal confidence. As far as they follow the same tract, they perfectly coincide in their results, which should procure confidence in the other; and they are made in situations much more analogous to the usual practical cases. This renders them doubly valuable. They are to be found in his two volumes entitled *Hydrodynamique*. He has opened this path of procedure in a manner so new and so judicious, that he has in some measure the merit of such as shall follow him in the same path.

This has been most candidly and liberally allowed him and the Chevalier du Buat, who has taken up the matter where the Abbé Bossut left it, and has prosecuted his experiments with great assiduity, and, we must now add, with singular success. By a very judicious consideration of the subject, he hit on a particular view of it, which saved him the trouble of a minute consideration of the small internal motions, and enabled him to proceed from a very general and evident proposition, which may be received as the key to a complete system of practical hydraulics. We shall follow this ingenious author in what we have further to say on the subject; and we doubt not but that our readers will think we do a service to the public by making these discussions of the Chevalier du Buat more generally known in this country. It must not however be expected that we shall give more than a synoptical view of them, connected by such familiar reasoning as may be either comprehended or confided in by persons not deeply versed in mathematical science.

SECT. I.—Theory of Rivers.

It is certain that the motion of open streams must, in some respects, resemble that of bodies sliding down inclined planes perfectly polished; and that they would accelerate continually, were they not obstructed; but they are obstructed, and frequently move uniformly. This can only arise from an equilibrium between the forces which promote their descent and those which oppose it. Du Buat, therefore, assumes the leading proposition, that,

When water flows uniformly on any channel or bed, the accelerating force which obliges it to move is equal to the sum of all the resistances which it meets with, whether arising from its own viscosity, or from the friction of its bed.

This law is as old as the formation of rivers, and should be the key of hydraulic science. Its evidence is clear; and it is, at any rate, the basis of all uniform motion. And since it is so, there must be some considerable analogy between the motion in pipes and in open channels. Both owe their origin to an inequality of pressure, both would accelerate continually if nothing hindered, and both are reduced to uniformity by the viscosity of the fluid and the friction of the channel.

It will therefore be convenient to examine the phenomena of water moving in pipes by the action of its weight only along the sloping channel. But, previously to this, we must take some notice of the obstruction to the entry of water into a channel of any kind, arising from the deflection of the many different filaments which press into the channel from the reservoir from every side. We shall then be able

Theory.

and the progressive experiments of Du Buat.

His leading proposition.

The subject of the following discussion proposed.

Theory. to separate this diminution of motion from the sum total that is observed, and ascertain what part remains as produced by the subsequent obstructions.

We shall then consider the principle of uniform motion, the equilibrium between the power and the resistance. The power is the relative height of the column of fluid which tends to move along the inclined plane of its bed; the resistance is the friction of the bed, the viscosity of the fluid, and its adhesion to the sides. Here is necessarily combined a number of circumstances which must be gradually detached, that we may see the effect of each, viz. the extent of the bed, its perimeter, and its slope. By examining the effects produced by variations of each of these separately, we discover what share each has in the general effect; and having thus analysed the complicated phenomena, we shall be able to combine those its elements, and frame a formula which shall comprehend every circumstance, from the greatest velocity to the extinction of all motion, and from the extent of a river to the narrow dimensions of a quill. We shall compare this formula with a series of experiments in all this variety of circumstances, partly made by Du Buat, and partly collected from other authors; and we shall leave the reader to judge of the agreement.

Confident that this agreement will be found most satisfactory, we shall then proceed to consider very cursorily the chief varieties which nature or art may introduce into these beds, the different velocities of the same stream, the intensity of the resistance produced by the inertia of the materials of the channel, and the force of the current by which it continually acts on this channel, tending to change either its dimensions or its form. We shall endeavour to trace the origin of these great rivers which spread like the branches of a vigorous tree, and occupy the surface even of a vast continent. We shall follow them in their course, unfold all their windings, study their train and regimen, and point out the law of its stability; and we shall investigate the causes of their deviations and wanderings.

The study of these natural laws pleases the mind: but it answers a still greater purpose; it enables us to assist nature, and to hasten her operations, which our wants and our impatience often find too slow. It enables us to command the elements, and to force them to administer to our wants and our pleasures.

We shall therefore, in the next place, apply the knowledge which we may acquire to the solution of the most important hydraulic questions which occur in the practice of the civil engineer.

We shall consider the effects produced by a permanent addition to any river or stream by the union of another, and the opposite effect produced by any draught or offset, showing the elevation or depression produced up the stream, and the change made in the depth and velocity below the addition or offset.

We shall pay a similar attention to the temporary swells produced by freshes.

We shall ascertain the effects of straightening the course of a stream, which, by increasing its slope, must increase its velocity, and therefore sink the waters above the place where the curvature was removed, and diminish the tendency to overflow, while the same immediate consequence must expose the places farther down to the risk of floods, from which they would otherwise have been free.

The effects of dams or weirs, and of bars, must then be considered; the gorge or swell which they produce up the stream must be determined for every distance from the weir or bar. This will furnish us with rules for rendering navigable or floatable such waters as have too little depth or too great slope. And it will appear that immense advantages may be thus derived, with a moderate expense, even from trifling brooks, if we will relinquish all prejudices, and not imagine that such conveyance is impossible be-

cause it cannot be carried on by such boats and small craft as we have been accustomed to look at. **Theory.**

The effects of canals of derivation, the rules or maxims of draining, and the general maxims of embankment, come in the next place; and our discussions will conclude with remarks on the most proper forms for the entry to canals, locks, docks, harbours, and mouths of rivers, the best shape for the starlings of bridges and of boats for inland navigation, and such like subordinate but interesting particulars, which will be suggested by the general thread of discussion.

It is considered as physically demonstrated (see HYDRO-NATURAL DYNAMICS), that water issuing from a small orifice in the velocity, bottom or side of a very large vessel, almost instantly acquires and maintains the velocity which a heavy body would acquire by falling to the orifice from the horizontal surface of the stagnant water. This we shall call its NATURAL VELOCITY. Therefore, if we multiply the area of the orifices by this velocity, the product will be the bulk or quantity of the water which is discharged. This we may call the NATURAL EXPENSE of water, or the NATURAL DISCHARGE.

Let O represent the area or section of the orifice expressed in some known measure, and h its depth under the surface. Let g express the velocity acquired by a heavy body during a second by falling. Let V be the medium velocity of the water's motion, Q the quantity of water discharged during a second, and N the natural expense.

We know that V is equal to $\sqrt{2g} \times \sqrt{h}$. Therefore $N = O \sqrt{2g} \sqrt{h}$.

If these dimensions be all taken in English feet, we have $\sqrt{2g}$ very nearly equal to 8; and therefore $V = 8 \sqrt{h}$, and $N = O 8 \sqrt{h}$.

But in our present business it is much more convenient to measure every thing by inches. Therefore, since a body acquires the velocity of 32 feet 2 inches in a second, we have $2g = 64$ feet 4 inches, or 772 inches, and $\sqrt{2g} = 27.78$ inches, nearly $27\frac{3}{4}$ inches.

Therefore $V = \sqrt{772} \sqrt{h} = 27.78 \sqrt{h}$, and $N = O \sqrt{772} \sqrt{h} = O 27.78 \sqrt{h}$.

But it is also well known, that if we were to calculate the expense or discharge for every orifice by this simple rule, we should in every instance find it much greater than nature really gives us.

When water issues through a hole in a thin plate, the lateral columns, pressing into the hole from all sides, cause the issuing filaments to converge to the axis of the jet, and contract its dimensions at a little distance from the hole. And it is in this place of greatest contraction that the water acquires that velocity which we observe in our experiments, and which we assume as equal to that acquired by falling from the surface. Therefore, that our computed discharge may best agree with observation, it must be calculated on the supposition that the orifice is diminished to the size of this smallest section. But the contraction is subject to variations, and the dimensions of this smallest section are at all times difficult to ascertain with precision. It is therefore much more convenient to compute from the real dimensions of the orifice, and to correct this computed discharge, by means of an actual comparison of the computed and effective discharges in a series of experiments made in situations resembling those cases which most frequently occur in practice. This correction, or its cause, in the mechanism of those internal motions, is generally called CONTRACTION by the writers on hydraulics; and it is not confined to a hole in a thin plate: it happens in some degree in all cases where fluids are made to pass through narrow places. It happens in the entry into all pipes, canals, and sluices; nay even into the passage of water over the edge of a board, such as is usually set up on the head of a

Theory. dam or weir, and even when this is immersed in water on both sides, as in a bar or keep, frequently employed for raising the waters of the level streams in Flanders in order to render them navigable. We mentioned an observation¹ of Du Buat to this effect, when he saw a gooseberry rise up from the bottom of the canal along the face of the bar, and then rapidly fly over its top. We have attempted to represent this motion of the filaments in these different situations.

Fig. 5.

Motion of filaments in various particular situations,

A shows the motion through a thin plate.

B shows the motion when a tube of about two diameters long is added, and when the water flows with a full mouth. This does not always happen in so short a pipe (and never in one that is shorter), but the water frequently detaches itself from the sides of the pipe, and flows with a contracted jet.

C shows the motion when the pipe projects into the inside of the vessel. In this case it is difficult to make it flow full.

D represents a mouth-piece fitted to the hole, and formed agreeably to that shape which a jet would assume of itself. In this case all contraction is avoided, because the mouth of this pipe may be considered as the real orifice, and nothing now diminishes the discharge but a trifling friction of the sides.

E shows the motion of water over a dam or weir, where the fall is free or unobstructed; the surface of the lower stream being lower than the edge or sole of the waste-board.

F is a similar representation of the motion of water over what we would call a *bar* or *keep*.

and the effects of contraction determined.

It was one great aim of the experiments of Michelotti and Bossut to determine the effects of contraction in these cases. Michelotti, after carefully observing the form and dimensions of the natural jet, made various mouth-pieces resembling it, till he obtained one which produced the smallest diminution of the computed discharge, or till the discharge computed for the area of its smaller end approached the nearest to the effective discharge. And he at last obtained one which gave a discharge of 983, when the natural discharge would have been 1000. This piece was formed by the revolution of a trochoid round the axis of the jet, and the dimensions were as follow:

Diameter of the outer orifice = 36
Diameter of the inner orifice = 46
Length of the axis = 96

The results of the experiments of the Abbé Bossut and of Michelotti scarcely differ, and they are expressed in the following table:

N or the natural expense.....10000 = 0.27.78 ✓
Q for the thin plate, fig. A, almost } 6526 = 0.18.13 ✓
at the surface..... }

Theory.

The numbers in the last column of this little table are the cubical inches of water discharged in a second when the height h is one inch.

It must be observed, that the discharges assigned here for the weir and bar relate only to the contractions occasioned by the passage over the edge of the board. The weir may also suffer a diminution by the contractions at its two ends, if it should be narrower than the stream, which is generally the case, because the two ends are commonly of square masonry or wood-work. The contraction there is nearly the same with that at the edge of a thin plate. But this could not be introduced into this table, because its effect on the expense is the same in quantity whatever is the length of the waste-board of the weir.

In like manner, the diminution of discharge through a sluice could not be expressed here. When a sluice is drawn up, but its lower edge still remains under water, the discharge is contracted both above and at the sides, and the diminution of discharge by each is in proportion to its extent. It is not easy to reduce either of these contractions to computation, but they may be very easily observed. We frequently can observe the water, at coming out of a sluice into a mill-course, quit the edge of the aperture, and show a part of the bottom quite dry. This is always the case when the velocity of efflux is considerable. When it is very moderate, this place is occupied by an eddy water almost stagnant. When the head of water is eight or ten inches, and runs off freely, the space left between it and the sides is about one and a half inch. If the sides of the entry have a slope, this void space can never appear; but there is always this tendency to convergence, which diminishes the quantity of the discharge.

It will frequently abridge computation very much to consider the water discharged in these different situations as moving with a common velocity, which we conceive as produced not by a fall from the surface of the fluid (which is exact only when the expense is equal to the natural expense), but by a fall h accommodated to the discharge: or it is convenient to know the height which would produce that very velocity which the water issues with in these situations.

And also, when the water is observed to be actually moving with a velocity V , and we know whether it is coming through a thin plate, through a tube, over a dam, &c. it is necessary to know the pressure or HEAD OF WATER h which has actually produced this velocity. It is convenient therefore to have the following numbers in readiness.

h for the natural expense..... = $\frac{V^2}{772}$
 h for a thin plate at the depth of 8 feet... = $\frac{V^2}{296}$
 h for a tube 2 diam. long..... = $\frac{V^2}{509}$
 h for a dam or weir..... = $\frac{V^2}{702}$
 h for a bar..... = $\frac{V^2}{731}$

It was necessary to premise these facts in hydraulics,

¹ See HYDRODYNAMICS, vol. xii.

Theory. that we may be able in every case to distinguish between the force expended in the entry of the water into the conduit or canal, and the force employed in overcoming the resistances along the canal, and in preserving or accelerating its motion in it.

The motion of rivers depends on the slope of the surface.

The motion of running water is produced by two causes: 1. The action of gravity; and, 2. the mobility of the particles, which makes them assume a level in confined vessels, or determines them to move to that side where there is a defect of pressure. When the surface is level, every particle is at rest, being equally pressed in all directions; but if the surface is not level, not only does a particle on the very surface tend by its own weight towards the lower side, as a body would slide along an inclined plane, but there is a force, external to itself, arising from a superiority of pressure on the upper end of the surface, which pushes this superficial particle towards the lower end; and this is not peculiar to the superficial particles, but affects every particle within the mass of water. In the vessel ACDE

(fig. 6), containing water with an inclined surface AE, if we suppose all frozen but the extreme columns AKHB, FGLE, and a connecting portion HKCDLG, it is evident, from hydrostatical laws, that the water on this connecting part will be pushed in the direction CD; and if the frozen mass BHGF were moveable, it would also be pushed along. Giving it fluidity will make no change in this respect; and it is indifferent what is the situation and shape of the connecting column or columns. The propelling force (MNF being horizontal) is the weight of the column AMNB. The same thing will obtain wherever we select the vertical columns. There will always be a force tending to push every particle of water in the direction of the declivity. The consequence will be, that the water will sink at one end and rise at the other, and its surface will rest in the horizontal position aOe , cutting the former in its middle O. This cannot be, unless there be not only a motion of perpendicular descent and ascent of the vertical columns, but also a real motion of translation from K towards L. It perhaps exceeds our mathematical skill to tell what will be the motion of each particle. Newton did not attempt it in his investigation of the motion of waves, nor is it at all necessary here. We may, however, acquire a very distinct notion of its general effect. Let OPQ be a vertical plane passing through the middle point O. It is evident that every particle in PQ, such as P, is pressed in the direction QD, with a force equal to the weight of a single row of particles whose length is the difference between the columns BH and FG. The force acting on the particle Q is, in like manner, the weight of a row of particles = AC — ED. Now if OQ, OA, OE, be divided in the same ratio, so that all the figures ACDE, BHGF, &c. may be similar, we see that the force arising solely from the declivity, and acting on each particle on the plane OQ, is proportional to its depth under the surface, and that the row of particles ACQDE, BHPGF, &c. which is to be moved by it, is in the same proportion. Hence it unquestionably follows, that the accelerating force on each particle of the row is the same in all. Therefore the whole plane OQ tends to advance forward together with the same velocity; and in the instant immediately succeeding, all these particles would be found again in a vertical plane indefinitely nearer to OQ; and if we sum up the forces, we shall find them the same as if OQ were the opening of a sluice, having the water on the side of D standing level with O, and the water on the other side standing at the height AC. This result is extremely different from that of the hasty theory of Guglielmini. He considers each particle in OQ as urged

Fig. 6.

by an accelerating force proportional to its depth, it is true; but he makes it *equal* to the weight of the row OP, and never recollects that the greatest part of it is balanced by an opposite pressure, nor perceives that the force which is not balanced must be distributed among a row of particles which varies in the same proportion with itself. When these two circumstances are neglected, the result will be incompatible with observation. When the balanced forces are taken into the account of pressure, it is evident that the surface may be supposed horizontal, and that motion should obtain in this case as well as in the case of a sloping surface; and indeed this is Guglielmini's professed theory, and what he highly values himself upon. He announces this discovery of a new principle, which he calls the energy of deep waters, as an important addition to hydraulics. It is owing to this, says he, that the great rivers are not stagnant at their mouths, where they have no perceptible declivity of surface, but, on the contrary, have greater energy and velocity than farther up, where they are shallower. This principle is the basis of his improved theory of rivers, and is insisted on at great length by all the subsequent writers. Buffon, in his theory of the earth, makes much use of it. We cannot but wonder that it has been allowed a place in the theory of rivers given in the great *Encyclopédie* of Paris, and in an article having the signature (O) of D'Alembert. We have been very anxious to show the falsity of this principle, because we consider it as a mere subterfuge of Guglielmini, by which he was able to patch up the mathematical theory which he had so hastily taken from Newton or Galileo; and we think that we have secured our readers from being misled by it, when we show that this energy must be equally operative when the surface is on a dead level. The absurdity of this is evident. We shall see by and by, that deep waters, when in actual motion, have an energy not to be found in shallow running waters, by which they are enabled to continue that motion; but this is not a moving principle; and it will be fully explained, as an immediate result of principles, not vaguely conceived and indistinctly expressed, like this of Guglielmini, but easily understood, and appreciable with the greatest precision. It is an energy common to all great bodies. Although they lose as much momentum in surmounting any obstacle as small ones, they lose but a small portion of their velocity. At present, employed only in considering the progressive motion of an open stream, whose surface is not level, it is quite enough that we see that such a motion must obtain, and that we see that there are propelling forces; that those forces arise *solely* from the want of a level surface, or from the slope of the surface; and that, with respect to any one particle, the force acting on it is proportional to the difference of level between each of the two columns (one on each side of the particle) which produce it. Were the surface level, there would be no motion; if it is not level, there will be motion; and this motion will be proportional to the want of level or the declivity of the surface: it is of no consequence whether the bottom be level or not, or what is its shape.

Hence we draw a fundamental principle, that the *motion of rivers depends entirely on the slope of the surface.*

The *slope* or declivity of any inclined plane is not properly expressed by the difference of height alone of its extremities: we must also consider its length; and the measure of the slope must be such that it may be the same while the declivity is the same. It must therefore be the same over the whole of any one inclined plane. We shall answer these conditions exactly, if we take for the measure of a slope the fraction which expresses the elevation of one extremity above the other divided by the length of the plane. Thus $\frac{AM}{AF}$ will express the declivity of the plane AF.

Theory. If the water met with no resistance from the bed in which it runs, if it had no adhesion to its sides and bottom, and if its fluidity were perfect, its gravity would accelerate its course continually, and the earth and its inhabitants would be deprived of all the advantages which they derive from its numberless streams. They would run off so quickly, that our fields, dried up as soon as watered, would be barren and useless. No soil could resist the impetuosity of the torrents; and their accelerating force would render them a destroying scourge, were it not that, by kind Providence, the resistance of the bed, and the viscosity of the fluid, become a check which reins them in and sets bounds to their rapidity. In this manner the friction on the sides, which, by the viscosity of the water, is communicated to the whole mass, and the very adhesion of the particles to each other, and to the sides of the channel, are the causes which make the resistances bear a relation to the velocity; so that the resistances, augmenting with the velocities, come at last to balance the accelerating force. Then the velocity now acquired is preserved, and the motion becomes uniform, without being able to acquire new increase, unless some change succeeds either in the slope or in the capacity of the channel. Hence arises the second maxim in the motion of rivers, that *when a stream moves uniformly, the resistance is equal to the accelerating force.*

As in the efflux of water through orifices, we pass over the very beginnings of the accelerated motion, which is a matter of speculative curiosity, and consider the motion in a state of permanency, depending on the head of water, the area of the orifice, the velocity, and the expense; so in the theory of the uniform motion of rivers, we consider the slope, the transverse section or area of the stream, the uniform velocity, and the expense. It will be convenient to affix precise meanings to the terms which we shall employ.

Terms precisely explained. The SECTION of a stream is the area of a plane perpendicular to the direction of the general motion.

The resistances arise ultimately from the action of the water on the internal surface of the channel, and must be proportional (*cæteris paribus*) to the extent of the action. Therefore, if we unfold the whole edge of this section, which is rubbed as it were by the passing water, we shall have a measure of the extent of this action. In a pipe, circular or prismatical, the whole circumference is acted on; but in a river or canal ACDR (fig. 6) the horizontal line aOe , which makes the upper boundary of the section $aCDe$, is free from all action. The action is confined to the three lines aC , CD , De . We shall call this line $aCDe$ the BORDER of the section.

The MEAN VELOCITY is that with which the whole section, moving equally, would generate a solid equal to the expense of the stream. This velocity is to be found perhaps but in one filament of the stream, and we do not know in which filament it is to be found.

Since we are attempting to establish an empirical theory of the motion of rivers, founded entirely on experiments, and palpable deductions from them, and since it is extremely difficult to make experiments on open streams which shall have a precision sufficient for such an important purpose, it would be a most desirable thing to demonstrate an exact analogy between the mutual balancing of the acceleration and resistance in pipes and in rivers; for in those we can not only make experiments with all the desired accuracy, and admitting precise measures, but we can make them in a number of cases that are almost impracticable in rivers. We can increase the slope of a pipe from nothing to the vertical position, and we can employ every desired degree of pressure, so as to ascertain its effect on the velocity in de-

grees which open streams will not admit of. The Chevalier du Buat has most happily succeeded in this demonstration, and it is here that his good fortune and his penetration have done so much service to practical science.

Let AB (fig. 7) be a horizontal tube, through which the water is impelled by the pressure or HEAD DA. This head is the moving power; and it may be conceived as consisting of two parts, performing two distinct offices. One of them is employed in impressing on the water that velocity with which it *actually moves* in the tube. Were there no obstructions to this motion, no greater head would be wanted; but there are obstructions, arising from friction, adhesion, and viscosity. This requires force. Let this be the office of the rest of the head of water in the reservoir. There is but one allotment, appropriation, or repartition of the whole head which will answer. Suppose E to be the point of partition, so that DE is the head necessary for impressing the actual velocity on the water (a head or pressure which has a relation to the form or circumstance of the entry, and the contraction which takes place there). The rest EA is wholly employed in overcoming the simultaneous resistances which take place along the whole tube AB, and is in equilibrium with this resistance. Therefore, if we apply at E a tube EC, of the same length and diameter with AB, and having the same degree of polish or roughness; and if this tube be inclined in such a manner that the axis of its extremity may coincide with the axis of AB in the point C; we affirm that the velocity will be the same in both pipes, and that they will have the same expense; for the moving force in the sloping pipe EC is composed of the whole weight of the column DE and the relative weight of the column EC; but this relative weight, by which alone it descends along the inclined pipe EC, is precisely equal to the weight of a vertical column EA of the same diameter. Everything therefore is equal in the two pipes, viz. the lengths, the diameters, the moving forces, and the resistances; therefore the velocities and discharges will also be equal.

This is not only the case on the whole, but also in every part of it. The relative weight of any part of it EK is precisely in equilibrium with the resistances along that part of the pipe; for it has the same proportion to the whole relative weight that the resistance has to the whole resistance. Therefore (*and this is the most important circumstance, and the basis of the whole theory*) the pipe EC may be cut shorter, or may be lengthened to infinity, without making any change in the velocity or expense, so long as the propelling head DE remains the same.

Leaving the whole head DA as it is, if we lengthen the horizontal pipe AB to G, it is evident that we increase the resistance without any addition of force to overcome it. The velocity must therefore be diminished; and it will now be a velocity which is produced by a smaller head than DE; therefore, if we were to put in a pipe of equal length at E, terminating in the horizontal line AG, the water will not run equally in both pipes. In order that it may, we must discover the diminished velocity with which the water now actually runs along AG, and we must make a head DI capable of impressing this velocity at the entry of the pipe, and then insert at I a pipe IH of the same length with AG. The expense and velocity of both pipes will now be the same.¹

Fig. 7.

The acceleration and resistance of water in a horizontal tube,

¹ We recommend it to the reader to make this distribution or allotment of the different portions of the pressure very familiar to his mind. It is of the most extensive influence in every question of hydraulics, and will on every occasion give him distinct conceptions of the internal procedure. Obvious as the thought seems to be, it has escaped the attention of all the writers on the subject.

Theory. What has now been said of a horizontal pipe AB would have been equally true of any inclined pipe AB A'B' (fig. 8). Drawing the horizontal line CB, we see that DC is the whole head or propelling pressure for either pipe AB or A'B'; and if DE is the head necessary for the actual velocity, EC is the head necessary for balancing the resistances; and the pipe EF, of the same length with AB, and terminating in the same horizontal line, will have the same velocity; and its inclination being thus determined, it will have the same velocity and expense whatever be its length.

Fig. 8.

Analogy
between
these pipes
and rivers
demonstrated
by Du
Buat.

Thus we see that the motion in any pipe, horizontal or sloping, may be referred to or substituted for the motion in another inclined pipe, whose head of water, above the place of entry, is that productive of the actual velocity of the water in the pipe. Now, in this case, the accelerating force is equal to the resistance: we may therefore consider this last pipe as a river, of which the bed and the slope are uniform or constant, and the current in a state of permanency; and we now may clearly draw this important conclusion, that pipes and open streams, when in a state of permanency, perfectly resemble each other in the circumstances which are the immediate causes of this permanency. The equilibrium between the accelerating force obtains not only in general, but takes place through the whole length of the pipe or stream, and is predicable of every individual transverse section of either. To make this more palpably evident, if possible, let us consider a sloping cylindrical pipe, the current of which is in a state of permanency. We can conceive it as consisting of two half cylinders, an upper and a lower. These are running together at an equal pace; and the filaments of each immediately contiguous to the separating plane and to each other are not rubbing on each other, nor affecting each other's motions in the smallest degree. It is true that the upper half is pressing on the lower, but in a direction perpendicular to the motion, and therefore not affecting the velocity; and we shall see presently, that although the lower side of the pipe bears somewhat more pressure than the other, the resistances are not changed. Indeed this odds of pressure is accompanied with a difference of motion, which need not be considered at present; and we may suppose the pipe so small or so far below the surface that this shall be insensible. Now let us suppose, that in an instant the upper half cylinder is annihilated: we then have an open stream; and every circumstance of accelerating force and of resistance remains precisely as it was. The motion must therefore continue as it did; and in this state the only accelerating force is the slope of the surface. The demonstration therefore is complete.

Consequence.

From these observations and reasonings we draw a general and important conclusion, "that the same pipe will be susceptible of different velocities, which it will preserve uniform to any distance, according as it has different inclinations; and each inclination of a pipe of given diameter has a certain velocity peculiar to itself, which will be maintained uniform to any distance whatever; and this velocity increases continually, according to some law, to be discovered by theory or experiment, as the position of the pipe changes from being horizontal till it becomes vertical; in which position it has the greatest uniform velocity possible relative to its inclination, or depending on inclination alone."

Theory. Let this velocity be called the TRAIN, or the RATE, of each pipe.

It is evident that this principle is of the utmost consequence in the theory of hydraulics; for by experiment we can find the train of any pipe. It is in train when an increase of length makes no change in the velocity. If lengthening the pipe increases the velocity, the slope of the pipe is too great, and *vice versa*. And having discovered the train of a pipe, and observed its velocity, and computed the head productive of this velocity with the contraction at the entry, the remainder of the head, that is, the slope (for this is equivalent to EA), is the measure of the resistance. Thus we obtain the measure of the resistance to the motion with a given velocity in a pipe of given diameter. If we change only the velocity, we get the measure of the new resistance relative to the velocity; and thus discover the law of relation between the resistance and velocity. Then, changing only the diameter of the pipe, we get the measure of the resistance relative to the diameter. This is the aim of a prodigious number of experiments made and collected by Du Buat, and which we shall not repeat, but only give the results of the different parts of his investigation.

Measure of the resistance to the motion with a given velocity.
Results of Du Buat's investigation on this subject.

We may express the slope of a pipe by the symbol $\frac{1}{s}$, 1 being an inch, for instance, and s being the slant length of a pipe which is one inch more elevated at one end than at the other. Thus a river which has a declivity of an inch and a half in 120 fathoms or 8640 inches, has its slope $= \frac{1\frac{1}{2}}{8640}$, or $\frac{1}{5760}$. But in order to obtain the hydraulic slope of a conduit-pipe, the height of the reservoir and place of discharge being given, we must subtract from the difference of elevation the height or head of water necessary for propelling the water into any pipe with the velocity V , which it is supposed actually to have. This is $\frac{V^2}{509}$. The remainder d is to be considered as the height of the declivity, which is to be distributed equally over the whole length l of the pipe, and the slope is then $\frac{d}{l} = \frac{1}{s}$.

There is another important view to be taken of the slope, which the reader should make very familiar to his thoughts. It expresses the proportion between the weight of the whole column which is in motion and the weight which is employed in overcoming the resistance; and the resistance to the motion of any column of water is equal to the weight of that column multiplied by the fraction $\frac{1}{s}$, which expresses its slope.

We now come to consider more particularly the resistances which in this manner bring the motion to a state of uniformity. If we consider the resistances which arise from a cause analogous to friction, we see that they must depend entirely on the inertia of the water. What we call the resistance is the diminution of a motion which *would* have been obtained but for these resistances; and the best way we have of measuring them is by the force which we must employ in order to keep up or restore this motion. We estimate this motion by a progressive velocity, which we mea-

Iecchi, in his *Hydraulics*, published in 1766, ascribes something like it to Daniel Bernoulli; but Bernoulli, in the passage quoted only speaks of the partition of pressure in the instant of opening an orifice. Part of it, says he, is employed in accelerating the quiescent water, and producing the velocity of efflux, and the remainder produces the pressure (now diminished) on the sides of the vessel. Bernoulli, Bossut, and all the good writers, make this distribution in express terms in their explanation of the motion of water through successive orifices; and it is surprising that no one before the Chevalier du Buat saw that the resistance arising from friction required a similar partition of the pressure; but though we should call this good fortune, we must ascribe to his great sagacity and justness of conception the beautiful use that he has made of it: *sum cuique*.

Theory. sure by the expense of water in a given time. We judge the velocity to diminish when the quantity discharged diminishes; yet it may be otherwise, and probably is otherwise. The absolute velocity of many, if not all, of the particles, may even be increased; but many of the motions being transverse to the general direction, the quantity of motion in this direction may be less, while the sum of the absolute motions of all the particles may be greater. When we increase the general velocity, it is not unreasonable to suppose that the impulses on all the inequalities are increased in this proportion; and the number of particles thus impelling and deflected at the same time will increase in the same proportion. The whole quantity, therefore, of these useless and lost motions will increase in the duplicate ratio of the velocities, and the force necessary for keeping up the motion will do so also; that is, the resistances should increase as the squares of the velocities.

Or if we consider the resistances as arising merely from the curvature of the imperceptible internal motions occasioned by the inequalities of the sides of the pipe, and as measured by the forces necessary for producing these curvilinear motions; then, because the curves will be the same whatever are the velocities, the deflecting forces will be as the squares of the velocities; but these deflecting forces are pressures, propagated from the parts urged or pressed by the external force, and are proportional to these external pressures by the principles of hydrostatics. Therefore the pressures or forces necessary for keeping up the velocities are as the squares of these velocities; and they are our only measures of the resistances which must be considered as following the same ratio. Whatever view therefore we take of the nature of these resistances, we are led to consider them as proportional to the squares of the velocities.

We may therefore express the resistances by the symbol $\frac{V^2}{m}$, m being some number to be discovered by experiment. Thus, in a particular pipe, the diminution of the motion or the resistance may be the 1000th part of the square of the velocity, and $R = \frac{V^2}{1000}$.

Now if g be the accelerating power of gravity on any particle, $\frac{g}{s}$ will be its accelerating power by which it would urge it down the pipe whose slope is $\frac{1}{s}$. Therefore, by the principle of uniform motion, the equality of the accelerating force, and the resistance, we shall have $\frac{V^2}{m} = \frac{g}{s}$, and $V\sqrt{s} = \sqrt{mg}$; that is, the product of the velocity, and the reciprocal of the square root of the slope, or the quotient of the velocity divided by the square root of the slope, is a constant quantity \sqrt{mg} for any given pipe; and the primary formula for all the uniform velocities of one pipe is

$$V = \frac{\sqrt{mg}}{\sqrt{s}}.$$

Experiments and reasoning of Du Buat, respecting these resistances, &c. Du Buat therefore examined this by experiment, but found, that even with respect to a pipe or channel which was uniform throughout, this was not true. We could give at once the final formula which he found to express the velocity in every case whatever; but this would be too empirical. The chief steps of his very sagacious investigation are instructive. We shall therefore mention them briefly, at least as far as they tend to give us any collateral information; and let it always be noted, that the instruction which they convey is not abstract speculation, but experimental truths, which must ever remain as an addition to our stock of knowledge, although Du Buat's deductions from them should prove false.

VOL. XIX.

Theory He found, in the first place, that in the same channel the product of V and \sqrt{s} increased as \sqrt{s} increased; that is, the velocities increased faster than the square roots of the slope, or the resistances did not increase as fast as the squares of the velocities. We beg leave to refer our readers to what we said on the resistance of pipes to the motion of fluids through them, in the article PNEUMATICS, when speaking of bellows. They will there see very valid reasons, we apprehend, for thinking that the resistances must increase more slowly than the squares of the velocities.

It being found, then, that $V\sqrt{s}$ is not equal to a constant quantity \sqrt{mg} , it becomes necessary to investigate some quantity depending on \sqrt{s} , or, as it is called, some function of \sqrt{s} which shall render \sqrt{mg} a constant quantity. Let X be this function of \sqrt{s} , so that we shall always have VX

equal to the constant quantity \sqrt{mg} , or $\frac{\sqrt{mg}}{X}$ equal to the

actual velocity V of a pipe or channel which is in train.

Du Buat, after many trials and reflections, the chief of which will be mentioned by and by, found a value of X which corresponded with a vast variety of slopes and velocities, from motions almost imperceptible, in a bed nearly horizontal, to the greatest velocities which could be produced by gravity alone in a vertical pipe; and when he compared them together, he found a very discernible relation between the resistances and the magnitude of the section; that is, that in two channels which had the same slope, and the same propelling force, the velocity was greatest in the channel which had the greatest section relative to its border. This may reasonably be expected. The resistances arise from the mutual action of the water and this border. The water immediately contiguous to it is retarded, and this retards the next, and so on. It is to be expected, therefore, that if the border, and the velocity, and the slope, be the same, the diminution of this velocity will be so much the less as it is to be shared among a greater number of particles; that is, as the area of the section is greater in proportion to the extent of its border. The diminution of the general or medium velocity must be less in a cylindrical pipe than in a square one of the same area, because the border of the section is less.

It appears evident, that the resistance of each particle is in the direct proportion of the whole resistance, and the inverse proportion of the number of particles which receive equal shares of it. It is therefore directly as the border, and inversely as the section. Therefore, in the expression $\frac{V^2}{m}$ which we have given for the resistance, the quantity m

cannot be constant, except in the same channel; and in different channels it must vary along with the relation of the section to its border, because the resistances diminish in proportion as this relation increases.

Without attempting to discover this relation by theoretical examination of the particular motions of the various filaments, Du Buat endeavoured to discover it by a comparison of experiments. But this required some manner of stating this proportion between the augmentation of the section and the augmentation of its border.

His statement is this: he reduces every section to a rectangular parallelogram of the same area, and having its base equal to the border unfolded into a straight line. The product of this base by the height of the rectangle will be equal to the area of the section. Therefore this height will be a representative of this valuable ratio of the section to its border (we do not mean that there is any ratio between a surface and a line: but the ratio of section to section is different from that of border to border; and it is the ratio of these ratios which is thus expressed by the height of this

Theory. rectangle). If S be the section, and B the border, $\frac{S}{B}$ is evidently a line equal to the height of this rectangle. Every section being in this manner reduced to a rectangle, the perpendicular height of it may be called the **HYDRAULIC MEAN DEPTH** of the section, and may be expressed by the symbol d . Buat calls it the mean radius. If the channel be a cylindrical pipe, or an open half cylinder, it is evident that d is half the radius. If the section is a rectangle, whose width is w and height h , the mean depth is $\frac{wh}{w+2h}$, &c. In general, if q represent the proportion of the breadth of a rectangular canal to its depth, that is, if q be made $= \frac{w}{h}$, we shall have $d = \frac{w}{q+2}$, or $d = \frac{qh}{q+2}$.

Now, since the resistances must augment as the proportion of the border to the section augments, m in the formulas $\frac{V^2}{w} = \frac{g}{s}$ and $V\sqrt{s} = \sqrt{mg}$ must follow the proportions of d , and the quantity \sqrt{mg} must be proportional to \sqrt{d} , for different channels, and $\frac{\sqrt{mg}}{\sqrt{d}}$ should be a constant quantity in every case.

A specious objection Our author was aware, however, of a very specious objection to the close dependence of the resistance on the extent of the border, and that it might be said that a double border did not occasion a double resistance, unless the pressure on all the parts was the same. For it may be naturally, and it is generally, supposed, that the resistance will be greater when the pressure is greater. The friction, or resistance analogous to friction, may therefore be greater on an inch of the bottom than on an inch of the sides; but M. d'Alembert and many others have demonstrated, that the paths of the filaments will be the same whatever be the pressures. This might serve to justify our ingenious author; but he was determined to rest every thing on experiment. He therefore made an experiment on the oscillation of water in syphons, which we have repeated in the following form, which is affected by the same circumstances, and is susceptible of much greater precision, and of more extensive and important application.

The two vessels $ABCD$, $abcd$ were connected by the syphon $EFGgfe$, which turned round in the short tubes E and e , without allowing any water to escape; the axis of these tubes being in one straight line. The vessels were about ten inches deep, and the branches FG , fg of the syphon were about five feet long. The vessels were set on two tables of equal height, and (the hole e being stopped) the vessel $ABCD$; and the whole syphon, were filled with water, and water was poured into the vessel $abcd$ till it stood at a certain height LM . The syphon was then turned into a horizontal position, and the plug drawn out of e , and the time carefully noted which the water employed in rising to the level HK hk in both vessels. The whole apparatus was now inclined so that the water ran back into $ABCD$. The syphon was now put in a vertical position, and the experiment was repeated. No sensible or regular difference was observed in the time. Yet in this experiment the pressure on the part Gg of the

Fig. 9.

syphon was more than six times greater than before. As it was thought that the friction on this small part (only six inches) was too small a portion of the whole obstruction, various additional obstructions were put into this part of the syphon, and it was even lengthened to nine feet; but still no remarkable difference was observed. It was even thought that the times were less when the syphon was vertical.

Thus Du Buat's opinion is completely justified; and he may be allowed to assert, that the resistance depends chiefly on the relation between the section and its border; and that $\frac{\sqrt{mg}}{\sqrt{d}}$ should be a constant quantity.

To ascertain this point was the object of the next series of experiments; to see whether this quantity was really constant, and, if not, to discover the law of its variation, and the physical circumstances which accompanied the variations, and may therefore be considered as their causes. A careful comparison of a very great number of experiments, made with the same slope, and with very different channels and velocities, showed that \sqrt{mg} did not follow the proportion of \sqrt{d} , nor of any power of \sqrt{d} . This quantity \sqrt{mg} increased by smaller degrees in proportion as \sqrt{d} was greater. In very great beds \sqrt{mg} was nearly proportional to \sqrt{d} ; but in smaller channels, the velocities diminished much more than \sqrt{d} did. Casting about for some way of accommodation, Du Buat considered, that some approximation at least would be had by taking off from \sqrt{d} some constant small quantity. This is evident: for such a diminution will have but a trifling effect when \sqrt{d} is great, and its effect will increase rapidly when \sqrt{d} is very small. He therefore tried various values for this subtraction, and compared the results with the former experiments; and he found, that in every case \sqrt{d} be diminished by one tenth of an inch, the calculated discharges would agree very exactly with the experiment. Therefore, instead of \sqrt{d} , he makes use of $\sqrt{d} - 0.1$, and finds this quantity always proportional to \sqrt{mg} , or finds that $\frac{\sqrt{mg}}{\sqrt{d} - 0.1}$ is a

constant quantity, or very nearly so. It varied from 297 to 287 in all sections, from that of a very small pipe to that of a little canal. In the large sections of canals and rivers it diminished still more, but never was less than 256.

This result is very agreeable to the most distinct notions that we can form of the mutual actions of the water and its bed. We see that when the motion of water is obstructed by a solid body, which deflects the passing filaments, the disturbance does not extend to any considerable distance on the two sides of the body. In like manner, the small disturbances, and imperceptible curvilinear motions, which are occasioned by the infinitesimal inequalities of the channel, must extend to a very small distance indeed from the sides and bottom of the channel. We know, too, that the mutual adhesion or attraction of water for the solid bodies which are moistened by it extends to a very small distance, which is probably the same, or nearly so, in all cases. Du Buat observed, that a surface of twenty-three square inches, applied to the surface of stagnant water, lifted 1601 grains; another of $5\frac{1}{2}$ square inches lifted 365; this was at the rate of sixty-five grains per inch nearly, making a column of about one sixth of an inch high. Now this effect is very much analogous to a real contraction of the capacity of the channel. The water may be conceived as nearly stagnant to this small distance from the border of the section. Or, to speak more accurately, the diminution of the progressive velocity occasioned by the friction and adhesion of the sides decreases very rapidly as we recede from the sides, and ceases to be sensible at a very small distance.

Theory.
and con-
firmed by
experi-
ment.

The writer of this article¹ verified the observation by a very simple and instructive experiment. He was making experiments on the production of vortices, in the manner suggested by Sir Isaac Newton, by whirling a very accurate and smoothly polished cylinder in water; and he found that the rapid motion of the surrounding water was confined to an exceedingly small distance from the cylinder, and it was not till after many revolutions that it was sensible even at the distance of half an inch. We may, by the way, suggest this as the best form of experiments for examining the resistances of pipes. The motion excited by the whirling cylinder in the stagnant water is equal and opposite to the motion lost by water passing along a surface equal to that of the cylinder with the same velocity. Be this as it may, we are justified in considering, with Du Buat, the section of the stream as thus diminished by cutting off a narrow border all round the touching parts, and supposing that the motion and discharge is the same as if the square root of the mean depth of the section were diminished by a small quantity, nearly constant. We see, too, that the effect of this must be insensible in great canals and rivers; so that, fortunately, its quantity is best ascertained by experiments made with small pipes. This is attended with another convenience, in the opinion of Du Buat, namely, that the effect of viscosity is most sensible in great masses of water in slow motion, and is almost insensible in small pipes, so as not to disturb these experiments. We may therefore assume 297 as the

general value of $\frac{\sqrt{mg}}{\sqrt{d}-0.1}$.²

Since we have $\frac{\sqrt{mg}}{\sqrt{d}-0.1} = 297$, we have also $m = \frac{297^2}{g}(\sqrt{d}-0.1)^2 = \frac{88209}{362}(\sqrt{d}-0.1)^2 = 243.7(\sqrt{d}-0.1)^2$. This we may express by $n(\sqrt{d}-0.1)^2$. And thus, when we have expressed the quantity of friction by $\frac{V^2}{m}$, the quantity m is variable, and its general value is

$\frac{V^2}{n(\sqrt{d}-0.1)^2}$, in which n is an invariable abstract number equal to 243.7, given by the nature of the resistance which water sustains from its bed, and which indicates its intensity.

And, lastly, since $m = n(\sqrt{d}-0.1)^2$, we have $\sqrt{mg} = \sqrt{ng}(\sqrt{d}-0.1)$, and the expression of the velocity V , which water acquires and maintains along any channel whatever, now becomes $V = \frac{\sqrt{ng}(\sqrt{d}-0.1)}{X}$, or $\frac{297(\sqrt{d}-0.1)}{X}$,

in which X is also a variable quantity, depending on the slope of the surface or channel, and expressing the accelerating force which, in the case of water in train, is in equilibrium with the resistances expressed by the numerator of the fraction.

Law of ac-
celeration
investi-
gated.

Having so happily succeeded in ascertaining the variations of resistance, let us accompany Du Buat in his investigation of the law of acceleration, expressed by the value of X .

Experience, in perfect agreement with any distinct opinions that we can form on this subject, had already shown him that the resistances increased in a slower ratio than that of the squares of the velocities, or that the velocities increased slower than \sqrt{s} . Therefore, in the formula

$V = \frac{\sqrt{ng}(\sqrt{d}-0.1)}{X}$, which, for one channel, we may ex-

press thus, $V = \frac{A}{X}$, we must admit that X is sensibly equal

Theory.

to \sqrt{s} when the slope is very small or s very great. But, that we may accurately express the velocity in proportion as the slope augments, we must have X less than \sqrt{s} ;

and, moreover, $\frac{\sqrt{s}}{X}$ must increase as \sqrt{s} diminishes. These

conditions are necessary that our values of V , deduced from

the formula $V = \frac{A}{X}$, may agree with the experiment.

In order to comprehend every degree of slope, we must particularly attend to the motion through pipes, because open canals will not furnish us with instances of exact TRAINS with great slopes and velocities. We can make

pipes vertical. In this case $\frac{1}{s}$ is $\frac{1}{1}$, and the velocity is the greatest possible for a train by the action of gravity: but we can give greater velocities than this by increasing the head of water beyond what produces the velocity of the train.

Let AB (fig. 10) be a vertical tube, and let CA be the head competent to the velocity in the tube, which we suppose to be in train. The slope is 1, and the full weight of the column in motion is the precise Fig. 10.

measure of the resistance. The value of $\frac{1}{s}$, con-

sidered as a slope, is now a maximum; but, considered as expressing the proportion of the weight of the column in motion to the weight which is in equilibrium with the resistance, it may not be a maximum; it may surpass unity, and s may be less than 1. For if the vessel be filled to E, the head of water is increased, and will produce a greater velocity, and this will produce a greater resistance. The velocity being now greater, the head EF which imparts it must be greater than CA. But it will not be equal to EA, because the uniform

velocities are found to increase faster than the square roots of the pressures. This is the general fact. Therefore F is above A, and the weight of the column FB, now employed to overcome the resistance, is greater than the weight of the column AB in motion. In such cases, therefore, $\frac{1}{s}$ greater than unity, is a sort of fictitious slope, and only represents the proportion of the resistance to the weight of the moving column. This proportion may surpass unity.

But it cannot be infinite: for, supposing the head of water infinite, if this produce a finite velocity, and we deduct from the whole height the height corresponding to this finite velocity, there will remain an infinite head, the measure of an infinite resistance produced by a finite velocity. This does not accord with the observed law of the velocities, where the resistances actually do not increase as fast as the squares of the velocities. Therefore an infinite head would have produced an infinite velocity, in opposition to the resistances: taking off the head of the tube, competent to this velocity, at the entry of the tube, which head would also be infinite, the remainder would in all probability be finite, balancing a finite resistance.

Therefore the value of s may remain finite, although the velocity be infinite; and this is agreeable to all our clearest notions of the resistances.

Adopting this principle, we must find a value of X which will answer all these conditions. 2. It must be sensibly proportional to \sqrt{s} , while s is great. It must always be less

¹ The late Professor Robison of Edinburgh.

² In this formula, and in the subsequent part of the investigation, French inches are employed. For English inches the constant number is 307.

Theory. than \sqrt{s} . 3. It must deviate from the proportion of \sqrt{s} so much the more as \sqrt{s} is smaller. 4. It must not vanish when the velocity is infinite. 5. It must agree with a range of experiments with every variety of channel and of slope.

We shall understand the nature of this quantity X better by representing by lines the quantities concerned in forming it.

If the velocities were exactly as the square roots of the slopes, the equilateral hyperbola NKS (fig. 11) between

Fig. 11.

its asymptotes MA, AB, would represent the equation

$V = \frac{A}{\sqrt{s}}$. The values of \sqrt{s} would be represented by the

abscissæ, and the velocities by the ordinates, and $Vs = A$ would be the power of the hyperbola. But since these ve-

locities are not sensibly equal to $\frac{A}{\sqrt{s}}$ except when \sqrt{s} is very

great, and deviate the more from this quantity as \sqrt{s} is smaller, we may represent the velocities by the ordinates of another curve PGT, which approaches very near to the hyperbola, at a great distance from A along AB; but separates from it when the abscissæ are smaller: so that if AQ represents that value of \sqrt{s} (which we have seen may become less than unity) which corresponds to an infinite velocity, the line QO may be the asymptote of the

new curve. Its ordinates are equal to $\frac{A}{X}$, while those of the

hyperbola are equal to $\frac{A}{\sqrt{s}}$. Therefore the ratio of these

ordinates, or $\frac{\sqrt{s}}{X}$, should be such that it shall be so much

nearer to unity as \sqrt{s} is greater, and shall surpass it so much the more as \sqrt{s} is smaller.

To express X , therefore, as some function of \sqrt{s} so as to answer these conditions, we see in general that X must be less than \sqrt{s} . And it must not be equal to any power of

\sqrt{s} whose index is less than unity, because then $\frac{\sqrt{s}}{X}$ would

differ so much the more from unity as \sqrt{s} is greater. Nor must it be any multiple of \sqrt{s} , such as $q\sqrt{s}$, for the same reason. If we make $X = \sqrt{s} - K$, K being a constant quantity, we may answer the first condition pretty well. But K must be very small, that X may not become equal to nothing, except in some exceedingly small value of \sqrt{s} . Now the experiments will not admit of this, because the

ratio $\frac{\sqrt{s}}{\sqrt{s} - K}$ does not increase sufficiently to correspond with the velocities which we observe in certain slopes, unless we make K greater than unity, which again is inconsistent with other experiments. We learn from such canvassing that it will not do to make K a constant quantity. If we should make it any fractionary power of \sqrt{s} , it would make $X = 0$, that is, nothing, when $s = 1$, which is also

Theory. contrary to experience. It would seem, therefore, that nothing will answer for K but some power of \sqrt{s} which has a variable index. The logarithm of \sqrt{s} has this property. We may therefore try to make $X = \sqrt{s} - \log. \sqrt{s}$. Ac-

cordingly, if we try the equation $V = \frac{A}{\sqrt{s} - \text{hyp. log. } \sqrt{s}}$,

we shall find a very great agreement with the experiments till the declivity becomes considerable, or about $\frac{1}{20}$, which is much greater than any river. But it will not agree with the velocities observed in some mill-courses, and in pipes of a still greater declivity, and gives a velocity that is too small; and in vertical pipes the velocity is not above one half of the true one. We shall get rid of most of these incongruities if we make K consist of the hyperbolic logarithm of \sqrt{s} augmented by a small quantity; and by trying various values for this constant quantity, and comparing the results with experiment, we may hit on one sufficiently exact for all practical purposes.

Du Buat, after repeated trials, found that he would have a very great conformity with experiment by making $K = \log. \sqrt{s} + 1.6$, and that the velocities exhibited in his experiments would be very well represented by the for-

$$V = \frac{297(\sqrt{s} - 0.1)}{\sqrt{s} - 1.6 \log. \sqrt{s} + 1.6}$$

There is a circumstance which our author seems to have overlooked on this occasion, and which is undoubtedly of great effect in these motions, viz. the mutual adhesion of the particles of water. This causes the water which is descending (in a vertical pipe, for example) to drag more water after it, and thus greatly increases its velocity. We

have seen an experiment in which the water issued from the bottom of a reservoir through a long vertical pipe having a very gentle taper. It was fifteen feet long, one inch diameter at the upper end, and two inches at the lower. The depth of the water in the reservoir was exactly one foot; in a minute there were discharged 2 $\frac{1}{2}$ cubic feet of water. It must therefore have issued through the hole in the bottom of the reservoir with the velocity of 8.85 feet per second. And yet we know that this head of water could not make it pass through the hole with a velocity greater than 6.56 feet per second. This increase must therefore have arisen from the cause we have mentioned, and is a proof of the great intensity of this force. We doubt not but that the discharge might have been much more increased by proper contrivances; and we know many instances in water-pipes where this effect is produced in a very great degree.

The following case is very distinct. Water is brought into the town of Dunbar, in the county of Haddington, from a spring at the distance of about 3200 yards. It is conveyed along the first 1100 yards in a pipe of two inches diameter, and the declivity is 12 feet 9 inches; from thence the water flows in a pipe of 1 $\frac{1}{2}$ inches diameter, with a declivity of 44 feet three inches, making in all 57 feet. When the work was carried as far as the two-inch pipe reached, the discharge was found to be 27 Scotch pints, of 103 $\frac{1}{2}$ cubic inches each, in a minute. When it was brought into the town, the discharge was 28. Here it is plain that the descent along the second stretch of the pipe could derive no impulsion from the first. This was only able to supply 27 pints, and to deliver it into a pipe of equal bore. It was not equivalent to the forcing it into a smaller pipe, and almost doubling its velocity. It must therefore have been dragged into this smaller pipe by the weight of what was descending along it, and this water was exerting a force equivalent to a head of 16 inches, increasing the velocity from 14 to about 28.

It must be observed, that if this formula be just, there can be no declivity so small that a current of water will not

Theory. take place in it. And accordingly none has been observed in the surface of a stream when this did not happen. But it also should happen with respect to any declivity of bottom. Yet we know that water will hang on the sloping surface of a board without proceeding further. The cause of this seems to be the adhesion of the water, combined with its viscosity. The viscosity of fluid presents a certain force which must be overcome before any current can take place.

A series of important experiments were made by our author in order to ascertain the relation between the velocity at the surface of any stream and that at the bottom. These are curious and valuable on many accounts. One circumstance deserves our notice here, viz. that *the differences between the superficial and bottom velocities of any stream are proportional to the square roots of the superficial velocities.* From what has been already said on the gradual diminution of the velocities among the adjoining filaments, we must conclude that the same rule holds good with respect to the velocity of separation of two filaments immediately adjoining. Hence we learn that this velocity of separation is in all cases indefinitely small, and that we may, without danger of any sensible error, suppose it a constant quantity in all cases.

We think, with our ingenious author, that on a review of these circumstances, there is a constant or invariable portion of the accelerating force employed in overcoming this viscosity, and producing this mutual separation of the adjoining filaments. We may express this part of the accelerating force by a part $\frac{1}{S}$ of that slope which constitutes

the whole of it. If it were not employed in overcoming this resistance, it would produce a velocity which (on account of this resistance) is not produced, or is lost. This

would be $\frac{A}{\sqrt{S-L}\sqrt{S}}$. This must therefore be taken from the velocity exhibited by our general formula. When thus

corrected, it would become $V = (\sqrt{d}-0.1) \left(\frac{\sqrt{ng}}{\sqrt{S-L}\sqrt{S}+1.6} - \frac{\sqrt{ng}}{\sqrt{S-L}\sqrt{S}} \right)$. But as the term $\frac{\sqrt{ng}}{\sqrt{S-L}\sqrt{S}}$ is com-

pounded only of constant quantities, we may express it by a single number. This has been collected from a scrupulous attention to the experiments (especially in canals and great bodies of water moving with very small velocities, in which case the effects of viscosity must become more remarkable), and it appears that it may be valued at $\sqrt{0.09}$ inch, or 0.3 inch very nearly.

From the whole of the foregoing considerations, drawn from nature, supported by such reasonings as our most distinct notions of the internal motions will admit, and authorized by a very extensive comparison with experiment, we are now in a condition to conclude a complete formula, expressive of the uniform motion of water, and involving every circumstance which appears to have any share in the operation.

Therefore, let

V represent the mean velocity, in inches per second, of any current of water, running uniformly, or which is in **TRAIN**, in a pipe or open channel, whose section, figure, and slope, are constant, but its length indefinite.

d The hydraulic mean depth, that is, the quotient arising from dividing the section of the channel, in square inches, by its border, expressed in linear inches.

s The reciprocal of the slope of the pipe, or of the surface of the current. It is the denominator of the fraction

expressing this slope, the numerator being always unity; and is had by dividing the expanded length of the pipe or channel by the difference of height of its two extremities.

g The velocity (in inches per second) which a heavy body acquires by falling during one second.

n An abstract constant number, determined by experiment to be 243.7.

L The hyperbolic logarithm of the quantity to which it is prefixed, and is had by multiplying the common logarithm of that quantity by 2.3026.

We shall have in every instance

$$V = \frac{\sqrt{ng}(\sqrt{d}-0.1)}{\sqrt{s-L}\sqrt{s}+1.6} - 0.3(\sqrt{d}-0.1).$$

This, in numbers, and English inches, is

$$V = \frac{307(\sqrt{d}-0.1)}{\sqrt{s-L}\sqrt{s}+1.6} - 0.3(\sqrt{d}-0.1);$$

and in French inches,

$$V = \frac{297(\sqrt{d}-0.1)}{\sqrt{s-L}\sqrt{s}+1.6} - 0.3(\sqrt{d}-0.1).$$

The following table contains the real experiments from which this formula was deduced, and the comparison of the real velocities with the velocities computed by the formula. It consists of two principal sets of experiments. The first are those made on the motion of water in pipes. The second are experiments made on open canals and rivers. In the first set, column 1st contains the number of the experiment; 2d, the length of the tube; 3d, the height of the reservoir; 4th, the values of *s*, deduced from columns second and third; 5th gives the observed velocities; and 6th, the velocities calculated by the formula.

In the second set, column 2d gives the area of the section of the channel; 3d, the border of the canal or circumference of the section, deducting the horizontal width, which sustains no friction; 4th, the square root \sqrt{d} of the hydraulic mean depth; 5th, the denominator *s* of the slope; 6th, the observed mean velocities; and 7th, the mean velocities by the formula. In the last ten experiments on large canals and a natural river, the 6th column gives the observed velocities at the surface.¹

The theory a well-founded probability.

The comparison must be acknowledged to be most satisfactory, and shows the great penetration and address of the author, in so successfully sifting and appreciating the share which each co-operating circumstance has had in producing the very intricate and complicated effect. It adds some weight to the principles on which he has proceeded in this analysis of the mechanism of hydraulic motion, and must give us great confidence in a theory so fairly established on a very copious induction. The author offers it only as a rational and well-founded probability. To this character it is certainly entitled; for the suppositions made in it are agreeable to the most distant notions we can form of these internal motions. And it must always be remembered, that the investigation of the formula, although it be rendered somewhat more perspicuous by thus having recourse to those motions, has no dependence on the truth of the principles. For it is, in fact, nothing but a classification of experiments, which are grouped together by some one circumstance of slope, velocity, form of section, &c. in order to discover the law of the changes which are induced by a variation of the circumstances which do not resemble. The procedure is precisely similar to that of the astronomer when he deduces the elements of an orbit from a multitude of observations. This was the task of the Chevalier du Buat; and he candidly and modestly informs us, that the finding out analytical forms of expression which would exhibit those changes, was the work of Mr Benezech de St Honore, an officer of engineers, and his colleague in the experi-

Theory.

mental course. It does honour to his skill and address; and we think the whole both a pretty and instructive specimen of the method of discovering the laws of nature in the midst of complicated phenomena. Daniel Bernoulli first gave the rules of this method, and they have been greatly improved by Lambert, Condorcet, and De la Grange. Mr Coulomb has given some excellent examples of their application to the discovery of the laws of friction, of magnetical and electrical attraction, &c. But this present work is the most perspicuous and familiar of them all. It is the empirical method of generalising natural phenomena, and of deducing general rules, of which we can give no other demonstration but that they are faithful representations of matters of fact. We hope that others, encouraged by the success of Du Buat, will follow this example, where public utility is preferred to a display of mathematical knowledge.

Although the author may not have hit upon the precise *modus operandi*, we agree with him in thinking that nature seems to act in a way not unlike what is here supposed. At any rate, the range of experiments is so extensive, and so multifarious, that few cases can occur which are not included among them. The experiments will always retain their value (as we presume that they are faithfully narrated), whatever may become of the theory; and we are confident that the formula will give an answer to any question to which it may be applicable, infinitely preferable to the vague guess of the most sagacious and experienced engineer.

We must however observe, that as the experiments on the pipes were all made with scrupulous care in the contrivance and execution of the apparatus, excepting only those of Mr Couplet on the main pipes at Versailles, we may presume that the formula gives the greatest velocities which can be expected. In ordinary works, where joints are rough or leaky, where drops of solder hang in the inside, where cocks intervene with deficient water-ways, where pipes have awkward bendings, contractions, or enlargements, and where they may contain sand or air, we should reckon on a smaller velocity than what results from our calculation; and we presume that an undertaker may with confidence promise four fifths of this quantity without any risk of disappointing his employer. We imagine that the actual performance of canals will be much nearer to the formula.

We have made inquiry after works of this kind executed in Britain, that we might compare them with the formula. But all our canals are locked and without motion; and we have only learned by an accidental information from Mr Watt, that a canal in his neighbourhood, which is eighteen feet wide at the surface, and seven feet at the bottom, and four feet deep, and has a slope of one inch in a quarter of a mile, runs with the velocity of seventeen inches per second at the surface, ten at the bottom, and fourteen in the middle. If we compute the motion of this canal by our formula, we shall find the mean velocity to be $13\frac{1}{2}$.

No river in the world has had its motion so much scrutinized as the Po about the end of the last century. It had been a subject of 100 years' continual litigation between the inhabitants of the Bolognese and the Ferrarese, whether the waters of the Rheno should be thrown into the Tronco de Venezia or Po Grande. This occasioned very numerous measures to be taken of its sections and declivity, and the quantities of water which it contained in its different states of fullness. But, unfortunately, the long-established methods of measuring waters which were in force in Lombardy, made no account of the velocity; and not all the entreaties of Castelli, Grandi, and other moderns, could prevail on the visitors in this process to deviate from the established methods. We have therefore no minute accounts of its velocity, though there are many rough estimates to be met with in that valuable collection published at Flo-

Theory. rence in 1723, of the writings on the motion of rivers. From them we have extracted the *only precise observations* which are to be found in the whole work.

Observa- The Po Grande receives no river from Stellata to the sea, and its slope in that interval is found most surprisingly uniform, namely, six inches in the mile (reduced to English measure). The breadth in its great freshes is 759 feet at Lago Scurio, with a very uniform depth of thirty-one feet. In its lowest state (in which it is called *Po Magra*), its breadth is not less than 700, and its depth about ten and a half.

The Rheno has a uniform declivity from the Ponte Emilio to Vigarano of fifteen inches per mile. Its breadth in its greatest freshes is 189 feet, and its depth nine.

Signor Corrade in his report says, that in the state of the great freshes the velocity of the Rheno is most exactly four fifths of that of the Po.

Grandi says, that, according to many observations of his own, a great fresh in the Rheno employs twelve hours to come from Ponte Emilio to Vigarano, which is thirty miles. This is a velocity of forty-four inches per second. And, by Corrade's proportion, the velocity of the Po Grande must be fifty-five inches per second.

Montanari's observation gives the Po Magra a velocity of thirty-one inches per second.

Let us compare these velocities with the velocities calculated by Du Buat's formula.

The hydraulic mean depths d and D of the Rheno and Po in the great freshes, deduced from the above measures, are 98.6 and 344 inches; and their slopes s and S are $\frac{1}{322}$ and $\frac{1}{10180}$. This will give

$$\frac{307(\sqrt{D}-0.1)}{\sqrt{S}-L\sqrt{S}+1.6}-0.3(\sqrt{D}-0.1)=52.176 \text{ inches, and}$$

$$\frac{307(\sqrt{d}-0.1)}{\sqrt{s}-L\sqrt{s}+1.6}-0.3(\sqrt{d}-0.1)=46.728 \text{ inches.}$$

These results differ very little from the velocities above mentioned. And if the velocity corresponding to a depth of thirty-one feet be deduced from that observed by Montanari in the Po Magra ten feet deep, on the supposition that they are in the proportion of \sqrt{d} , it will be found to be about fifty-three and a half inches per second.

Highly to This comparison is therefore highly to the credit of the theory, and would have been very agreeable to Du Buat had he known it, as we hope it is to our readers.

We have collected many accounts of water-pipes, and made the comparisons, and we flatter ourselves that these have enabled us to improve the theory. They shall appear in their proper place; and we may just observe here, that the two-inch pipe, which we formerly spoke of as conveying the water to Dunbar, should have yielded only 25 $\frac{3}{4}$ Scotch pints per minute by the formula, instead of 27; a small error.

We have, therefore, no hesitation in saying, that this single formula of the uniform motion of water is one of the most valuable presents which natural science and the arts have received during the course of this century.

A table containing the values of $\frac{307}{\sqrt{s}-L\sqrt{s}+1.6}$ ready calculated for every declivity that can occur in water-pipes, canals, or rivers, is given in the article WATER-WORKS. Aided by this, which supersedes the only difficult part of the computation, a person can calculate the velocity for any proposed case in less than five minutes.

We have now established in some measure a THEORY OF HYDRAULICS, by exhibiting a general theorem which expresses the relation of the chief circumstances of all such motions as have attained a state of permanency, in so far as

this depends on the magnitude, form, and slope of the channel. This permanency we have expressed by the term TRAIN, saying that the stream is *in train*.

We proceed to consider the subordinate circumstances contained in this theorem; such as, 1st, The forms which nature or art may give to the bed of a running stream, and the manner of expressing this form in our theorem. 2d, The gradations of the velocity, by which it decreases in the different filaments, from the axis or most rapid filament to the border; and the connection of this with the mean velocity, which is expressed by our formula. 3d, Having acquired some distinct notions of this, we shall be able to see the manner in which undisturbed nature works in forming the beds of our rivers, the forms which she affects, and which we must imitate in all their local modifications, if we would secure that permanency which is the evident aim of all her operations. We shall here learn the mutual action of the current and its bed, and the circumstances which insure the stability of both. These we may call the *regimen* or the *conservation* of the stream, and may say that it is *in regimen*, or *in conservation*. This has a relation, not to the dimensions and the slope alone, or to the accelerating force and the resistance arising from mere inertia; it respects immediately the tenacity of the bed, and is different from the *train*.

4th, These pieces of information will explain the deviation of rivers from the rectilinear course, the resistance occasioned by these deviations, and the circumstances on which the regimen of a winding stream depends.

§ 1. Of the Forms of the Channel.

The numerator of the fraction which expresses the velocity of a river in train has \sqrt{d} for one of its factors. That form, therefore, is most favourable to the motion which gives the greatest value to what we have called the hydraulic mean depth d . This is the prerogative of the semicircle, and here d is equal to half the radius; and all other figures of the same area are the more favourable, as they approach nearer to a semicircle. This is the form, therefore, of all conduit-pipes, and should be taken for aqueducts which are built of masonry. Ease and accuracy of execution, however, have made engineers prefer a rectangular form; but neither of these will do for a channel formed out of the ground.

We shall soon see that the semicircle is incompatible with a regimen; and if we proceed through the regular polygons, we shall find that the half hexagon is the only one which has any pretensions to a regimen; yet experience shows us, that even its banks are too steep for almost any soil. A dry earthen bank, not bound together by grass roots, will hardly stand with a slope of forty-five degrees; and a canal which conveys running waters will not stand with this slope. Banks whose base is to their height as four to three will stand very well in moist soils, and this is a slope very usually given. This form is even affected in the spontaneous operations of nature, in the channels which she digs for the rills and rivulets in the higher and steeper grounds.

This form has some mathematical and mechanical properties which entitle it to some further notice. Let ABEC (fig. 12) be such a trapezium, and AHGC the rectangle of equal width and depth. Bisect HB and EC by the verticals FD and KI, and draw the verticals AB, CE. Because AH : HB = 3 : 4, we have AB = 5, and BD = 2, and FD = 3, and BD + DF = BA. From these premises it follows, that the trapezium ABEC has the same area with the rectangle FDIK; for HB being bisected in D, the triangles AOF, BOD are equal. Also the border ABEC, which is touched by the passing stream, is equal to FDIK.

Fig. 12.

Theory. Therefore the mean depth, which is the quotient of the area divided by the border, is the same in both; and this is the case, whatever is the width BE at the bottom, or even though there be no rectangle such as bBEe interposed between the slant sides.

Best form of a channel.

Of all rectangles, that whose breadth is twice the height, or which is half of a square, gives the greatest mean depth. If, therefore, FK be double of FD, the trapezium ABEC, which has the same area, will have the largest mean depth of any such trapezium, and will be the best form of a channel for conveying running waters. In this case, we have AC = 10, AH = 3, and BE = 2. Or we may say that the best form is a trapezium, whose bottom width is $\frac{2}{3}$ of the depth, and whose extreme width is $\frac{10}{3}$. This form approaches very near to that which the torrents in the hills naturally dig for themselves in uniform ground, where their action is not checked by stones which they lay bare, or which they deposit in their course. This shows us, and it will be fully confirmed by and by, that the channel of a river is not a fortuitous thing, but has a relation to the consistency of the soil and velocity of the stream.

A rectangle, whose breadth is $\frac{2}{3}$ of the depth of water, will therefore have the same depth with a triangle whose surface width is $\frac{2}{3}$ of its vertical depth; for this is the dimensions when the rectangle bBEe is taken away.

Let A be the area of the section of any channel, w its width (when rectangular), and h its depth of water. Then

what we have called its mean depth, or d, will be $\frac{A}{w + 2h}$

$= \frac{w h}{w + 2h}$. Or if q expresses the ratio of the width to

the depth of a rectangular bed, that is, if $q = \frac{w}{h}$, we have

a very simple and ready expression for the mean depth, either from the width or depth. For $d = \frac{w}{q + 2}$, or $d =$

$$\frac{q h}{q + 2}.$$

Therefore, if the depth were infinite, and the width finite, we should have $d = \frac{w}{2}$; or if the width be infinite, and the

depth finite, we have $d = h$. And these are the limits of the values of d; and therefore in rivers whose width is always great in comparison of the depth, we may without much error take their real depth for their hydraulic mean depth. Hence we derive a rule of easy recollection, and which will at all times give us a very near estimate of the velocity and expense of a running stream, viz. that the velocities are nearly as the square roots of the depths. We find this confirmed by many experiments of Micheltotti.

Estimate of the expense of a running stream.

Also, when we are allowed to suppose this ratio of the velocities and depths, that is, in a rectangular canal of great breadth and small depth, we shall have the quantities discharged nearly in the proportion of the cubes of the velocities. For the quantity discharged d is as the velocity and area jointly, that is, as the height and velocity jointly, because when the width is the same the area is as the height. Therefore, we have $d \propto h v$. But, by the above remark, $h \propto v^2$. Therefore, $d \propto v^3$; and this is confirmed by the experiments of Bossut, vol. ii. 236. Also, because d is as $v h$, when w is constant, and by the above remark (allowable when w is very great in proportion to h) v is as \sqrt{h} , we have d as $h\sqrt{h}$, or $h^{\frac{3}{2}}$, or the squares of the discharges proportional to the cubes of the heights in rectangular beds, and in their corresponding trapeziums.

1. Knowing the mean depth and the proportion of the

width and real depth, we can determine the dimensions of the bed, and we have $w = q d + 2 d$, and $h = d + \frac{2d}{q}$.

Theory. Rules for finding the

2. If we knew the area and mean depth, we can in like manner find the dimensions, that is, w and h; for $A = w h$,

$$\text{and } d = \frac{w h}{w + 2h}; \text{ therefore } w = \pm \sqrt{\frac{A^2}{4d^2} - 2A} + \frac{A}{2d}.$$

3. If d be known, and one of the dimensions be given, we can find the other; for $d = \frac{w h}{w + 2h}$ gives $w = \frac{2 h d}{h - d}$

$$\text{and } h = \frac{w d}{w - 2d}.$$

4. If the velocity V and the slope s for a river in mean train be given, we can find the mean depth; for $V = \text{depth}$,

$$\left(\frac{307}{\sqrt{s} - L\sqrt{s} + 1.6} - 0.3 \right) (\sqrt{d} - 0.1). \text{ Whence we}$$

$$\text{deduce } \sqrt{d} - 0.1 = \frac{V}{\frac{307}{\sqrt{s} - L\sqrt{s} + 1.6} - 0.3},$$

and $\sqrt{d} =$ to this quantity $+ 0.1$.

5. We can deduce the slope which will put in train slope, a river whose channel has given dimensions. We make

$$\frac{307 (\sqrt{d} - 0.1)}{V + 0.3 (\sqrt{d} - 0.1)} = \sqrt{s}. \text{ This should be } = \sqrt{s} -$$

$L\sqrt{s} + 1.6$, which we correct by trials, which will be exemplified when we apply these doctrines to practice.

Having thus established the relation between the different circumstances of the form of the channel to our general formula, we proceed to consider,

§ 2. The Gradations of Velocity from the middle of the Stream to the sides.

The knowledge of this is necessary for understanding the regimen of a river; for it is the velocity of the filaments in contact with the bed which produces any change in it, and occasions any preference of one to another in respect of regimen or stability. Did these circumstances not operate, the water, true to the laws of hydraulics, and confined within the bounds which have been assigned them, would neither enlarge nor diminish the area of the channel. But this is all that we can promise of waters perfectly clear, running in pipes or hewn channels. But rivers, brooks, and smaller streams, carry along waters loaded with mud or sand, which they deposit wherever their velocity is checked; and they tear up, on the other hand, the materials of the channel wherever their velocity is sufficiently great. Nature, indeed, aims continually at an equilibrium, and works without ceasing to perpetuate her own performances, by establishing an equality of action and re-action, and proportioning the forms and direction of the motions to her agents, and to local circumstances. Her work is slow but unceasing; and what she cannot accomplish in a year she will do in a century. The beds of our rivers have acquired some stability, because they are the labour of ages; and it is to time that we owe those deep and wide valleys which receive and confine our rivers in channels, which are now consolidated, and with slopes which have been gradually moderated, so that they no longer either ravage our habitations or confound our boundaries. Art may imitate nature, and, by directing her operations (which she still carries on according to her own imprescriptible laws) according to our views, we can hasten her progress, and accomplish our purpose, during the short period of human life. But we can do this only by studying the unalterable laws of mechanism. These are presented to us by spontaneous nature. Fre-

Nature to be imitated in making artificial streams.

Theory. quently we remain ignorant of their foundation; but it is not necessary for the prosperity of the subject that he have the talents of the senator; he can profit by the statute without understanding its grounds. It is so in the present instance. We have not as yet been able to infer the law of retardation observed in the filaments of a running stream from any sound mechanical principle. The problem, however, does not appear beyond our powers, if we assume, with Sir Isaac Newton, that the velocity of any particular filament is the arithmetical mean between those of the filaments immediately adjoining. We may be assured, that the filament in the axis of an inclined cylindrical tube, of which the current is in train, moves the fastest, and that all those in the same circumference round it are those which glide along the pipe. We may affirm the same thing of the motions in a semicylindrical inclined channel conveying an open stream. But even in these we have not yet demonstrated the ratio between the extreme velocities, nor in the different circles. This must be decided experimentally.

And here we are under great obligations to Du Buat. He has compared the velocities in the axes of a prodigious number and variety of streams, differing in size, form, slope, and velocity, and has computed in them all the mean velocities, by measuring the quantities of water discharged in a given time. His method of measuring the bottom velocity was simple and just. He threw in a gooseberry, as nearly as possible of the same specific gravity with the water. It was carried along the bottom almost without touching it.

Laws of the velocities of different portions of the stream.

He discovered the following laws: 1. In small velocities the velocity in the axis is to that at the bottom in a ratio of considerable inequality. 2. This ratio diminishes as the velocity increases, and in very great velocities approaches to the ratio of equality. 3. What was most remarkable was, that neither the magnitude of the channel, nor its slope, had any influence in changing this proportion, while the mean velocity remained the same. Nay, though the stream ran on a channel covered with pebbles or coarse sand, no difference worth noticing was to be observed from the velocity over a polished channel. 4. And if the velocity in the axis is constant, the velocity at the bottom is also constant, and is not affected by the depth of water or magnitude of the stream. In some experiments the depth was thrice the width, and in others the width was thrice the depth. This changed the proportion of the magnitude of the section to the magnitude of the rubbing part, but made no change on the ratio of the velocities. This is a thing which no theory could point out.

Mean velocity,

Another most important fact was also the result of his observation, viz. that *the mean velocity in any pipe or open stream is the arithmetical mean between the velocity in the axis and the velocity at the sides of a pipe or bottom of an open stream.* We have already observed, that the ratio of the velocity in the axis to the velocity at the bottom diminished as the mean velocity increased. This variation he was enabled to express in a very simple manner, so as to be easily remembered, and to enable us to tell any one of them by observing another.

If we take unity from the square root of the superficial velocity, expressed in inches, the square of the remainder is the velocity at the bottom; and the mean velocity is the half sum of these two. Thus, if the velocity in the middle of the stream be 25 inches per second, its square root is five; from which if we take unity, there remains four. The square of this, or 16, is the velocity at the bottom, and $\frac{25 + 16}{2}$, or 20½, is the mean velocity.

This is a very curious and most useful piece of informa-

Theory. tion. The velocity in the middle of the stream is the easiest measured of all, by any light small body floating down; and the mean velocity is the one which regulates the train, the discharge, the effect on machines, and all the most important consequences.

We may express this by a formula of most easy re-expression. Let V be the mean velocity, v the velocity in the collection. Let V be the mean velocity, v the velocity in the axis, and u the velocity at the bottom; we have

$$u = (\sqrt{v} - 1)^2, \text{ and } V = \frac{v + u}{2}.$$

$$\text{Also } v = (\sqrt{V - 1} + \frac{1}{2})^2, \text{ and } v = (\sqrt{u} + 1)^2.$$

$$V = (\sqrt{v} - \frac{1}{2})^2 + \frac{1}{4}, \text{ and } V = (\sqrt{u} + \frac{1}{2})^2 + \frac{1}{4}.$$

$$u = (\sqrt{v} - 1)^2, \text{ and } u = (\sqrt{V - \frac{1}{4}} - \frac{1}{2})^2.$$

Also $v - u = 2\sqrt{V - \frac{1}{4}}$ and $v - V = V - u = \sqrt{V - \frac{1}{4}}$; that is, the difference between these velocities increases in the ratio of the square roots of the mean velocities diminished by a small constant quantity.¹

This may perhaps give the mathematicians some help in ascertaining the law of degradation from the axis to the sides. Thus, in a cylindrical pipe, we may conceive the current as consisting of an infinite number of cylindrical shells sliding within each other like the draw-tubes of a spy-glass. Each of these is in equilibrio, or as much accelerated by the one within it as it is retarded by the one without; therefore, as the *momentum* of each diminishes in the proportion of its diameter (the thickness being supposed the same in all), the velocity of separation must increase by a certain law from the sides to the axis. The magnitude of the small constant quantity here spoken of seems to fix this law.

The place of the mean velocity could not be discovered with any precision. In moderate velocities it was not more than one fourth or one fifth of the depth distant from the bottom. In very great velocities it was sensibly higher, but never in the middle of the depth.

The knowledge of these three velocities is of great importance. The superficial velocity is easily observed, hence the mean velocity is easily computed. This multiplied by the section gives the expense; and if we also measure the expanded border, and then obtain the hydraulic mean depth (or \sqrt{d}), we can, by the formula of uniform motion, deduce the slope, or, knowing the slope, we can deduce any of the other circumstances.

The following table of these three velocities will save the trouble of calculation in one of the most frequent questions of hydraulics.

Velocity in Inches.			Velocity in Inches.

The knowledge of the velocity at the bottom is of the greatest use for enabling us to judge of the action of the stream on its bed; and we shall now make some observations on this particular.

Operation
of the
stream on
its bed,

Every kind of soil has a certain velocity consistent with the stability of the channel. A greater velocity would enable the waters to tear it up, and a smaller velocity would permit the deposition of more moveable materials from above. It is not enough, then, for the stability of a river, that the accelerating forces are so adjusted to the size and figure of its channel that the current may be in train: it must also be in equilibrium with the tenacity of the channel.

We learn from observation, that a velocity of three inches per second at the bottom will just begin to work upon fine clay fit for pottery, and however firm and compact it may be, it will tear it up. Yet no beds are more stable than clay when the velocities do not exceed this: for the water soon takes away the impalpable particles of the superficial clay, leaving the particles of sand sticking by their lower half in the rest of the clay, which they now protect, making a very permanent bottom, if the stream does not bring down gravel or coarse sand, which will rub off this very thin crust, and allow another layer to be worn off. A velocity of six inches will lift fine sand; eight inches will lift sand as coarse as linseed; twelve inches will sweep along fine gravel; twenty-four inches will roll along rounded pebbles an inch diameter; and it requires three feet per second at the bottom to sweep along shivery angular stones of the size of an egg.

Theory.

how car-
ried on.

The manner in which unwearied nature carries on some of these operations is curious, and deserves to be a little noticed. All must recollect the narrow ridges or wrinkles which are left on the sand by a temporary fresh or stream. They are observed to lie across the stream, and each ridge consists of a steep face AD, BF (fig. 13), which looks down the stream, and a gentler slope DB, FC, which connects this

Fig. 13.

with the next ridge. As the stream comes over the first steep AD, it is directed almost perpendicularly against the point E immediately below D, and thus it gets hold of a particle of coarse sand, which it could not have detached from the rest had it been moving parallel to the surface of it. It easily rolls it up the gentle slope EB; arrived there, the particle tumbles over the ridge, and lies close at the bottom of it at F, where it is protected by the little eddy, which is formed in the very angle; other particles lying about E are treated in the same way, and, tumbling over the ridge B, cover the first particle, and now protect it effectually from any farther disturbance. The same operation is going on at the bottom of each ridge. The brow or steep of the ridge gradually advances down the stream, and the whole set change their places, as represented by the line *adbf*; and after a certain time the particle which was deposited in F is found in an unprotected situation, as it was in E, and it now makes another step down the stream.

The Abbé Bossut found, that when the velocity of the stream was just sufficient for lifting the sand (and a small excess hindered the operation altogether), a ridge advanced about twenty feet in a day.

Since the current carries off the most moveable matters of the channel, it leaves the bottom covered with the remaining coarse sand, gravel, pebbles, and larger stones. To these are added many which come down the stream while it is more rapid, and also many which roll in from the sides as the banks wear away. All these form a bottom much more solid and immoveable than a bottom of the medium soil would have been. But this does not always maintain the channel in a permanent form, but frequently occasions great changes, by obliging the current, in the event of any sudden fresh or swell, to enlarge its bed, and even to change it altogether, by working to the right and to the left, since it cannot work downwards. It is generally from such accumulation of gravel and pebbles in the bottom of the bed that rivers change their channels.

It remains to ascertain, in absolute measures, the force which a current really exerts in attempting to drag along with it the materials of its channel; and which *will* produce this effect unless resisted by the inertia of these materials. It is therefore of practical importance to know this force.

Nor is it abstruse or difficult. For when a current is in train, the accelerating force is in equilibrio with the resistance, and is therefore its immediate measure. Now this accelerating force is precisely equal to the weight of the body of water in motion multiplied by the fraction which expresses the slope. The mean depth being equal to the quotient of the section divided by the border, the section is equal to the product of the mean depth multiplied by the border. Therefore, calling the border *b*, and the mean depth *d*, we have the section = *db*. The body of water in motion is therefore *db*s (because *s* was the slant length of a part whose difference of elevation is 1), and the accele-

Theory.

rating force is $db s \times \frac{1}{s}$, or db . But if we would only consider this resistance as corresponding to an unit of the length of the channel, we must divide the quantity db by s , and the resistance is then $\frac{db}{s}$. And if we would consider the resistance only for an unit of the border, we must divide this expression by b ; and thus this resistance (taking an inch for the unit) will be expressed for one square inch of the bed by the weight of a bulk of water which has a square inch for its base, and $\frac{d}{s}$ for its height. And lastly, if E be taken for any given superficial extent of the channel or bed, and F the obstruction, which we consider as a sort of friction, we shall have $F = \frac{Ed}{s}$.

Thus, let it be required to determine in pounds the resistance or friction on a square yard of a channel whose current is in train, which is ten feet wide, four feet deep, and has a slope of one foot in a mile. Here E is nine feet. Ten feet width and four feet depth give a section of forty feet. The border is eighteen feet. Therefore $d = \frac{40}{18} = 2.2222$, and s is 5280. Therefore the friction is the weight of a column of water whose base is nine feet, and height $\frac{2.2222}{5280}$, or nearly $3\frac{1}{10}$ ounces avoirdupois.

§ 3. Settlement of the Beds of Rivers.

Simplicity and wisdom displayed in the conduct of rivers.

He who looks with a careless eye at a map of the world, is apt to consider the rivers which ramble over its surface as a chance-medley disposition of the drainers which carry off the waters. But it will afford a most agreeable object to a considerate and contemplative mind to take it up in this very simple light; and, having considered the many ways in which the drenched surface might have been cleared of the superfluous waters, to attend particularly to the very way which nature has followed. In pursuing the troubled waters of a mountain torrent, or the pure streams which trickle from their bases, till he sees them swallowed up in the ocean, and in attending to the many varieties in their motions, he will be delighted with observing how the simple laws of mechanism are made so fruitful in good consequences, both by modifying the motions of the waters themselves, and also by inducing new forms on the surface of the earth, fitted for re-acting on the waters, and producing those very modifications of their motions which render them so beneficial. The permanent beds of rivers are by no means fortuitous gutters hastily scooped out by dashing torrents; but both they and the valleys through which they flow are the patient but unceasing labours of nature, prompted by goodness and directed by wisdom.

Whether we trace a river from the torrents which collect the superfluous waters of heaven, or from the springs which discharge what would otherwise be condemned to perpetual inactivity, each feeder is but a little rill, which could not ramble far from its scanty source among growing plants and absorbent earth, without being sucked up and evaporated, did it not meet with other rills in its course. When united, they form a body of water still inconsiderable, but much more able, by its bulk, to overcome the little obstacles to its motion; and the rivulet then moves with greater speed, as we have now learned. At the same time, the surface exposed to evaporation and absorption is diminished by the union of the rills. Four equal rills have only the surface of two when united. Thus the portion which escapes

Theory

arrestment, and travels downward, is continually increasing. This is a happy adjustment to the other operations of nature. Were it otherwise, the lower and more valuable countries would be loaded with the passing waters in addition to their own surplus rains, and the immediate neighbourhood of the sea would be almost covered by the drains of the interior countries. But, fortunately, those passing waters occupy less room as they advance, and by this wise employment of the most simple means, not only are the superfluous waters drained off from our fertile fields, but the drains themselves become an useful part of the country by their magnitude. They become the habitation of a prodigious number of fishes, which share the Creator's bounty; and they become the means of mutual communication of all the blessings of cultivated society. The vague ramblings of the rivers scatter them over the face of the country, and bring them to every door. It is not even an indifferent circumstance, that they gather strength to cut out deep beds for themselves. By this means they cut open many springs. Without this, the produce of a heavy shower would make a swamp which would not dry up in many days. And it must be observed, that the same heat which is necessary for the vigorous growth of useful plants will produce a very copious evaporation. This must return in showers much too copious for immediate vegetation, and the overplus would be destructive. Is it not pleasant to contemplate this adjustment of the great operations of nature, so different from each other, that if chance alone directed the detail, it was almost an infinite odds that the earth would be uninhabitable?

But let us follow the waters in their operations, and note the face of the countries through which they flow. Attend- ing to the breadth, the depth, and the slope of the valleys, we shall be convinced that their present situation is extremely different from what it was in ancient days; and that the valleys themselves are the works of the rivers, or at least of waters which have descended from the heights, loaded with all the lighter matters which they were able to bring away with them. The rivers now flow in beds which have a considerable permanency; but this has been the work of ages. This has given stability, both by filling up and smoothing the valleys, and thus lessening the changing causes, and also by hardening the beds themselves, which are now covered with aquatic plants, and lined with the stones, gravel, and coarser sand, out of which all the lighter matters have been washed away.

The surface of the high grounds is undergoing a continual change; and the ground on which we now walk is by no means the same which was trodden by our remote ancestors. The showers from heaven carry down into the valleys, or sweep along by the torrents, a part of the soil which covers the heights and steepes. The torrents carry this soil into the brooks, these deliver part of it into the great rivers, and these discharge this fertilizing fat of the earth into the sea, where it is swallowed up, and for ever lost for the purposes of vegetation. Thus the hillocks lose of their height, the valleys are filled up, and the mountains are laid bare and show their naked precipices, which formerly were covered over with flesh and skin, but now look like the skeleton of this globe. The low countries, raised and nourished for some time by the substance of the high lands, will go in their turn to be buried in the ocean; and then the earth, reduced to a dreary flat, will become an immense uninhabitable mass. This catastrophe is far distant, because this globe is in its youth, but it is not the less certain; and the united labours of the human race could not long protract the term.

But, in the mean time, we can trace a beneficent purpose, and a nice adjustment of seemingly remote circumstances. The grounds near the sources of all our rivers are indeed gradually stripped of their most fertile ingredi-

Theory.
Benefi-
cance dis-
played in
the chan-
ges they
produce.

ents. But had they retained them for ages, the sentient inhabitants of the earth, or at least the nobler animals, with man at their head, would not thence have derived much advantage. The general laws of nature produce changes in our atmosphere which must ever render these great elevations unfruitful. That genial warmth, which is equally necessary for the useful plant as for the animal which lives on it, is confined to the lower grounds. The earth, which on the top of Mount Hæmus could only bring forth moss and dittany, when brought into the gardens of Spalatro produced pot-herbs so luxuriant, that Diocletian told his colleague Maximian that he had more pleasure in their cultivation than the Roman empire could confer. Thus nature not only provides us manure, but conveys it to our fields. She even keeps it safe in store for us till it shall be wanted. The tracts of country which are but newly inhabited by man, such as great part of America, and the newly-discovered regions of Terra Australis, are still almost occupied by marshes and lakes, or covered with impenetrable forests; and they would remain long enough in this state, if population, continually increasing, did not increase industry, and multiply the hands of cultivators along with their necessities. The Author of Nature was alone able to form the huge ridges of the mountains, to model the hillocks and the valleys, to mark out the courses of the great rivers, and give the first trace to every rivulet; but has left to man the task of draining his own habitation and the fields which are to support him, because this is a task not beyond his powers. It was therefore of immense advantage to him that those parts of the globe into which he has not yet penetrated should remain covered with lakes, marshes, and forests, which keep in store the juice of the earth, which the influence of the air and the vivifying warmth of the sun would have expended long ere now in useless vegetation, and which the rains of heaven would have swept into the sea, had they not been thus protected by their situation or their cover. It is therefore the business of man to open up these mines of hoarded wealth, and to thank the Author of all good, who has thus husbanded them for his use, and left them as a rightful heritage for those of after days.

The earth had not in the remote ages, as in our day, those great canals, those capacious voiders, always ready to drain off the rain-waters (of which only part is absorbed by the thirsty ground) and the pure waters of the springs from the foot of the hills. The rivers did not then exist, or were only torrents, whose waters, confined by the gulleys and glens, are searching for a place to escape. Hence arise those numerous lakes in the interior of great continents, of which there are still remarkable relics in North America, which in process of time will disappear, and become champaign countries. The most remote from the sea, unable to contain its waters, finds an issue through some gorge of the hills, and pours over its superfluous waters into a lower basin, which, in its turn, discharges its contents into another, and the last of the chain delivers its waters by a river into the ocean. The communication was originally begun by a simple overflowing at the lowest part of the margin. This made a torrent, which quickly deepened its bed; and this circumstance increasing its velocity, as we have seen, would extend this deepening backward to the lake, and draw off more of its waters. The work would go on rapidly at first, while earth and small stones only resisted the labours of nature; but these being washed away, and the channel hollowed out to the firm rock on all sides, the operation must go on very slowly, till the immense cascade shall undermine what it cannot break off, and then a new discharge will commence, and a quantity of flat ground will emerge all round the lake. The torrent, in the mean time, makes its way down the country, and digs a canal, which may be called the first sketch of a river, which will deepen and widen its bed continually. The water of several basins

united, and running together in a great body, will, according to the principles which we have established, have a much greater velocity, with the same slope, than those of the lakes in the interior parts of the continent; and the sum of them all united in the basin next the sea, after having broken through its natural mound, will make a prodigious torrent, which will dig for itself a bed so much the deeper as it has more slope and a greater body of waters.

The formation of the first valleys, by cutting open many springs which were formerly concealed under ground, will add to the mass of running waters, and contribute to drain off the waters of these basins. In course of time many of them will disappear, and flat valleys among the mountains and hills are the traces of their former existence.

When nature thus traces out the courses of future rivers, it is to be expected that those streams will most deepen their channels which in their approach to the sea receive into their bed the greatest quantities of rain and spring-waters, and that towards the middle of the continent they will deepen their channels less. In these last situations the natural slope of the fields causes the rain-water, rills, and the little rivulets from the springs, to seek their ways to the rivers. The ground can sink only by the flattening of the hills and high grounds; and this must proceed with extreme slowness, because it is only the gentle though incessant work of the rains and springs. But the rivers, increasing in bulk and strength, and of necessity flowing over every thing, form to themselves capacious beds in a more yielding soil, and dig them even to the level of the ocean.

The beds of rivers by no means form themselves in one inclined plane. If we should suppose a canal AB (fig. 14) perfectly straight and horizontal at B, where it joins with the sea, this canal would really be an inclined channel of greater and greater slope as it is farther from B. This is evident; because gravity is directed towards the centre of the earth, and the angle CAB contained between the channel and the plumb-line at A is smaller than the similar angle CDB; and consequently the inclination to the horizon is greater in A than in D. Such a canal, therefore, would make the bed of a river; and some have thought that this was the real form of nature's work; but the supposition is a whim, and it is false. No river has a slope at all approaching to this. It would be eight inches declivity in the mile next the ocean, twenty-four inches in the second mile, forty inches in the third, and so on in the duplicate ratio (for the whole elevation) of the distances from the sea. Such a river would quickly tear up its bed in the mountains (were there any grounds high enough to receive it), and, except its first cascade, would soon acquire a more gentle slope. But the fact is, and it is the result of the imprescriptible laws of nature, that the continued track of a river is a succession of inclined channels, whose slope diminishes by steps as the river approaches to the sea. It is not enough to say that this results from the natural slope of the countries through which it flows, which we observe to increase in declivity as we go to the interior parts of the continent. Were it otherwise, the equilibrium at which nature aims in all her operations would still produce the gradual diminution of the slope of rivers. Without it they could not be in a permanent train.

That we may more easily form a notion of the manner in which the permanent course of a river is established, let us suppose a stream or rivulet *sa* (fig. 15) far up the country, makes its way through a soil perfectly uniform to the sea, taking the course *s a b c d e f*, and receiving the permanent additions of the stream *g a*, *h b*, *i c*, *h d*, *l e*, and that its velocity and slope in all its parts are so suited to the tenacity

Theory.

Fig. 15.

of the soil and magnitude of its section, that neither do its waters during the annual freshes tear up its banks or deepen its bed, nor do they bring down from the high lands materials which they deposit in the channel in times of smaller velocity. Such a river may be said to be in a *permanent state*, to be in *conservation*, or to have *stability*. Let us call this state of a river its *REGIMEN*, denoting by the word the proper adjustment of the velocity of the stream to the tenacity of the channel. The velocity of its regimen must be the same throughout, because it is this which regulates its action on the bottom, which is the same from its head to the sea. That its bed may have stability, the mean velocity of the current must be constant, notwithstanding the inequality of discharge through its different sections by the brooks which it receives in its course, and notwithstanding the augmentation of its section as it approaches the sea.

On the other hand, it behoved this exact regimen to commence at the mouth of the river, by the working of the whole body of the river, in concert with the waters of the ocean, which always keep within the same limits, and make the ultimate level invariable. This working will begin to dig the bed, giving it as little breadth as possible: for this working consists chiefly in the efforts of falls and rapid streams, which arise of themselves in every channel which has too much slope. The bottom deepens, and the sides remain very steep, till they are undermined and crumbled down; and being then diluted in the water, they are carried down the stream and deposited where the ocean checks its speed. The banks crumble down anew, the valley or hollow forms; but the section, always confined to its bottom, cannot acquire a great breadth, and it retains a good deal of the form of the trapezium formerly mentioned. In this manner does the regimen begin to be established from *f* to *e*.

With respect to the next part *d e*, the discharge or produce is diminished by the want of the brook *l e*. It must take a similar form, but its area will be diminished, in order that its velocity may be the same; and its mean depth *d* being less than in the portion *e f* below, the slope must be greater. Without these conditions we could not have the uniform velocity, which the assumed permanency in an uniform soil naturally supposes. Reasoning after the same manner for all the portions *e d*, *b c*, *a b*, *s a*, we see that the regimen will be successively established in them, and that the slope necessary for this purpose will be greater as we approach the river head. The vertical section or profile of the course of the river *s a b c d e f* will therefore resemble the line *S A B C D E F* which is sketched above, having its different parts variously inclined to the horizontal line *I I F*.

This process of nature

confirmed by example.

Such is the process of nature to be observed in every river on the surface of the globe. It long appeared a kind of puzzle to the theorists; and it was this observation of the increasing, or at least this continued velocity with smaller slope, as the rivers increased by the addition of their tributary streams, which caused Guglielmini to have recourse to his new principle, the energy of deep waters. We have now seen in what this energy consists. It is only a greater quantity of motion remaining in the middle of a great stream of water after a quantity has been retarded by the sides and bottom; and we see clearly, that since the addition of a

new and perhaps an equal stream does not occupy a bed of double surface, the proportion of the retardations to the remaining motion must continually diminish as a river increases by the addition of new streams. If therefore the slope were not diminished, the regimen would be destroyed, and the river would dig up its channel. We have a full confirmation of this in the many works which have been executed on the Po, which runs with rapidity through a rich and yielding soil. About the year 1600 the waters of the Panaro, a very considerable river, were added to the Po Grande; and although it brings along with it in its freshes a vast quantity of sand and mud, it has greatly deepened the whole Tronco di Venezia from the confluence to the sea. This point was clearly ascertained by Manfredi about the year 1720, when the inhabitants of the valleys adjacent were alarmed by the project of bringing in the waters of the Rheno, which then ran through the Ferrarese. Their fears were overcome, and the Po Grande continues to deepen its channel every day, with a prodigious advantage to the navigations; and there are several extensive marshes which now drain off by it, after having been for ages under water: and it is to be particularly remarked, that the Rheno is the foulest river in its freshes of any in that country. We insert this remark, because it may be of great practical utility, as pointing out a method of preserving and even improving the depth of rivers or drains in flat countries, which is not obvious, but rather appears improper; but it is strictly conformable to a true theory, and to the operations of nature, which never fails to adjust every thing so as to bring about an equilibrium. Whatever the declivity of the country may have been originally, the regimen begins to be settled at the mouths of the rivers, and the slopes are diminished in succession as we recede from the coast. The original slopes inland may have been much greater; but they will (when busy nature has completed her work) be left somewhat, and only so much greater, that the velocity may be the same notwithstanding the diminution of the section and mean depth.

Freshes will disturb this methodical progress relative Effects of only to the successive permanent additions; but their effects chiefly accelerate the deepening of the bed, and the diminution of the slope, by augmenting the velocity during their continuance. But when the regimen of the permanent additions is once established, the freshes tend chiefly to widen the bed, without greatly deepening it: for the aquatic plants, which have been growing and thriving during the peaceable state of the river, are now laid along, but not swept away, by the freshes, and protect the bottom from their attacks; and the stones and gravel, which must have been left bare in a course of years, working on the soil, will also collect in the bottom, and greatly augment its power of resistance; and even if the floods should have deepened the bottom some small matter, some mud will be deposited as the velocity of the freshes diminishes, and this will remain till the next flood.

We have supposed the soil uniform throughout the whole course; this seldom happens; therefore the circumstances which insure permanency, or the regimen of a river, may be very different in its different parts and in different rivers. We may say in general, that the farther that the regimen has advanced up the stream in any river, the more slowly will it convey its waters to the sea.

There are some general circumstances in the motion of rivers which it will be proper to take notice of just now, that they may not interrupt our more minute examination of their mechanism; and their explanations will then occur of themselves as corollaries of the propositions which we shall endeavour to demonstrate.

In a valley of small width the river always occupies the lowest part of it; and it is observed, that this is seldom in the middle of the valley, and is nearest to that side on which the slope from the higher grounds is steepest, and this with-

Theory.

hills.

out regard to the line of its course. The river generally adheres to the steepest hills, whether they advance into the plain or retire from it. This general feature may be observed over the whole globe. It is divided into compartments by great ranges of mountains; and it may be observed, that the great rivers hold their course not very far from them, and that their chief feeders come from the other side. In every compartment there is a swell of the low country at a distance from the bounding ridge of mountains; and on the summit of this swell the principal feeders of the great river have their sources.

The name *valley* is given with less propriety to these immense regions, and is more applicable to tracts of champaign land which the eye can take in at one view. Even here we may observe a resemblance. It is not always in the very lowest part of this valley that the river has its bed: although the waters of the river flow in a channel below its immediate banks, these banks are frequently higher than the grounds at the foot of the hills. This is very distinctly seen in Lower Egypt, by means of the canals which are carried backward from the Nile for accelerating its fertilizing inundations. When the calishes are opened to admit the waters, it is always observed that the districts most remote are the first covered, and it is several days before the immediately adjoining fields partake of the blessing. This is a consequence of that general opinion of nature by which the valleys are formed. The river in its floods is loaded with mud, which it retains as long as it rolls rapidly along its limited bed, tumbling its waters over and over, and taking up in every spot as much as it deposits: but as soon as it overflows its banks, the very enlargement of its section diminishes the velocity of the water; and it may be observed still running in the track of its bed with great velocity, while the waters on each side are stagnant at a very small distance: therefore the water, on getting over the banks, must deposit the heaviest, the firmest, and even the greatest part of its burden, and must become gradually clearer as it approaches the hills. Thus a gentle slope is given to the valley in a direction which is the reverse of what one would expect. It is, however, almost always the case in wide valleys, especially if the great river comes through a soft country. The banks of the brooks and ditches are observed to be deeper as they approach the river, and the merely superficial drains run backwards from it.

The bed
of rivers is
enlarged
near the
sea,

We have already observed that the enlargement of the bed of a river, in its approach to the sea, is not in proportion to the increase of its waters. This would be the case even if the velocity continued the same; and, therefore, since the velocity increases in consequence of the greater energy of a large body of water, which we now understand distinctly, a still smaller bed is sufficient for conveying all the water to the sea.

the water
being
checked by
the tides
of the
ocean.

This general law is broken, however, in the immediate neighbourhood of the sea; because in this situation the velocity of the water is checked by the passing flood-tides of the ocean. As the whole waters must still be discharged, they require a larger bed, and the enlargement will be chiefly in width. The sand and mud are deposited when the motion is retarded. The depth of the mouth of the channel is therefore diminished. It must therefore become wider. If this be done on a coast exposed to the force of a regular tide, which carries the waters of the ocean across the mouth of the river, this regular enlargement of the mouth will be the only consequence, and it will generally widen till it washes the foot of the adjoining hills; but if there be no tide in the sea, or a tide which does not set across the mouth of the river, the sands must be deposited at the sides of the opening, and become additions to the shore, lengthening the mouth of the channel. In this sheltered situation, every trivial circumstance will cause the river to work more on particular parts of the bottom, and

Theory.

deepen the channel there. This keeps the mud suspended in such parts of the channel, and it is not deposited till the stream has shot farther out into the sea. It is deposited on the sides of those deeper parts of the channel, and increases the velocity in them, and thus still farther protracts the deposition. Rivers so situated will not only lengthen their channels, but will divide them, and produce islands at their mouths. A bush, a tree torn up by the roots by a mountain torrent, and floated down the stream, will thus inevitably produce an island; and rivers in which this is common will be continually shifting their mouths. The Mississippi is a most remarkable instance of this. It has a long course through a rich soil, and disembogues itself into the bay of Mexico, in a place where there is no *passing tide*, as may be seen by comparing the hours of high water in different places. No river that we know carries down its stream such numbers of rooted-up trees; they frequently interrupt the navigation, and render it always dangerous in the night-time. This river is so beset with flats and shifting sands at its mouth, that the most experienced pilots are puzzled; and it has protruded its channel above fifty miles in the short period that we have known it. The discharge of the Danube is very similar: so is that of the Nile, for it is discharged into a still corner of the Mediterranean. It may now be said to have acquired considerable permanency; but much of this is owing to human industry, which strips it as much as possible of its subsidence matter. The Ganges, too, is in a situation pretty similar, and exhibits similar phenomena. The Maragnon might be noticed as an exception; but it is not an exception. It has flowed very far in a level bed, and its waters come pretty clear to Para; but, besides, there is a strong transverse tide, or rather current, at its mouth, setting to the south-east both during flood and ebb. The mouth of the Po is perhaps the most remarkable of any on the surface of this globe, and exhibits appearances extremely singular. Its discharge is into a sequestered corner of the Adriatic. Though there be a more remarkable tide in this gulf than in any part of the Mediterranean, it is still but trifling, and it either sets directly in upon the mouth of the river or retires straight away from it. The river has many mouths, and they shift prodigiously. There has been a general increase of the land very remarkable. The marshes where Venice now stands were in the Augustan age everywhere penetrable by the fishing-boats, and in the fifth century could only bear a few miserable huts; now they are covered with crowds of stately buildings. Ravenna, situated on the southernmost mouth of the Po, was, in the Augustan age, at the extremity of a swamp, and the road to it was along the top of an artificial mound, made by Augustus at an immense expense. It was, however, a fine city, containing extensive docks, arsenals, and other massy buildings, being the great military port of the empire, where Augustus laid up his great ships of war. In the Gothic times it became almost the capital of the western empire, and was the seat of government and of luxury. It must therefore be supposed to have every accommodation of opulence, and we cannot doubt of its having paved streets, wharfs, &c.; so that its wealthy inhabitants were at least walking dryfooted from house to house. But now it is an Italian mile from the sea, and surrounded with vineyards and cultivated fields, and is accessible in every direction. All this must have been formed by depositions from the Po, flowing through Lombardy loaded with the spoils of the Alps, which were here arrested by the reeds and bulrushes of the marsh. These things are in common course; but when wells are dug, we come to the pavements of the ancient city, and these pavements are all on one exact level, and they are *eight feet below the surface of the sea at low water*. This cannot be ascribed to the subsiding of the ancient city. This would be irregular, and greatest among the sea

Theory. buildings. The tomb of Theodoric remains, and the pavement round it is on a level with all the others. The lower story is always full of water; so is the lower story of the cathedral to the depth of three feet. The ornaments of both these buildings leave no room to doubt that they were formerly dry; and such a building as the cathedral could not sink without crumbling into pieces.

It is by no means easy to account for all this. The depositions of the Po and other rivers must raise the ground; and yet the rivers must still flow over all. We must conclude that the surface of the Adriatic is by no means level, and that it slopes like a river from the Lagoon of Venice to the eastward. In all probability it even slopes considerably outwards from the shore. This will not hinder the alternations of ebb and flow tide, as will be shown in its proper place. The whole shores of this gulf exhibit most uncommon appearances.

Rivers are convex athwart the stream, and the cause of it.

The last general observation which we shall make in this place is, that the surface of a river is not flat, considered athwart the stream, but convex; this is owing to its motion. Suppose a canal of stagnant water; its surface would be a perfect level. But suppose it possible, by any means, to give the middle waters a motion in the direction of its length, they must drag along with them the waters immediately contiguous. These will move less swiftly, and will in like manner drag the waters without them; and thus the water at the sides being abstracted, the depth must be less, and the general surface must be convex across. The fact in a running stream is similar to this; the side waters are withheld by the sides, and every filament is moving more slowly than the one next it towards the middle of the river, but faster than the adjoining filament on the land side. This alone must produce a convexity of surface. But besides this, it is demonstrable that the pressure of a running stream is diminished by its motion, and the diminution is proportional to the height which would produce the velocity with which it is gliding past the adjoining filament. This convexity must in all cases be very small. Few rivers have the velocity nearly equal to eight feet per second, and this requires a height of one foot only. An author quoted by M. Buffon says, that he has observed on the river Avenir an elevation of three feet in the middle during floods; but we suspect some error in the observation.

§ 4. *Of the Windings of Rivers.*

Winding course of rivers, how formed.

Rivers are seldom straight in their course. Formed by the hand of nature, they are accommodated to every change of circumstance. They wind around what they cannot get over, and work their way to either side according as the resistance of the opposite bank makes a straight course more difficult; and this seemingly fortuitous rambling distributes them more uniformly over the surface of a country, and makes them everywhere more at hand, to receive the numberless rills and rivulets which collect the waters of our springs and the superfluities of our showers, and to comfort our habitations with the many advantages which cultivation and society can derive from their presence. In their feeble beginnings the smallest inequality of slope or consistency is enough to turn them aside and make them ramble through every field, giving drink to our herds and fertility to our soil. The more we follow nature into the minutiae of her operations, the more must we admire the inexhaustible fertility of her resources, and the simplicity of the means by which she produces the most important and beneficial effects. By thus twisting the course of our rivers into ten thousand shapes, she keeps them long amidst our fields, and thus compensates for the declivity of the surface, which would otherwise tumble them with great rapidity into the ocean, loaded with the best and richest of our soil. Without this, the showers of heaven would have little influence

in supplying the waste of incessant evaporation. But as things are, the rains are kept slowly trickling along the sloping sides of our hills and steeps, winding round every clod, nay, every plant, which lengthens their course, diminishes their slope, checks their speed, and thus prevents them from quickly brushing off from every part of the surface the lightest and best of the soil. The steepest of our holm lands would be too steep, and the rivers would shoot along through our finest meadows, hurrying every thing away with them, and would be unfit for the purposes of inland conveyance, if the inequalities of soil did not make them change this headlong course for the more beautiful meanders which we observe in the course of the small rivers winding through our meadows. Those rivers are in general the straightest in their course which are the most rapid, and which roll along the greatest bodies of water: such are the Rhone, the Po, the Danube. The smaller rivers continue more devious in their progress, till they approach the sea, and have gathered strength from all their tributary streams.

Theory.

Every thing aims at an equilibrium, and this directs even the rambling of rivers. It is of importance to understand the relation between the force of a river and the resistance which the soil opposes to those deviations from a rectilinear course; for it may frequently happen that the general procedure of nature may be inconsistent with our local purposes. Man was set down on this globe, and the task of cultivating it was given him by nature, and his chief enjoyment seems to be to struggle with the elements. He must not find things to his mind, but he must mould them to his own fancy. Yet even this seeming anomaly is one of nature's most beneficent laws; and his exertions must still be made in conformity with the general train of the operations of mechanical nature; and when we have any work to undertake relative to the course of rivers, we must be careful not to thwart their general rules, otherwise we shall sooner or later be punished for their infraction. Things will be brought back to their former state, if our operations are inconsistent with that equilibrium which is constantly aimed at, or some new state of things which is equivalent will soon be induced. If a well-regulated river has been improperly deepened in some place to answer some particular purpose of our own, or if its breadth has been improperly augmented, we shall soon see a deposition of mud or sand choke up our fancied improvements; because, as we have enlarged the section without increasing the slope or the supply, the velocity must diminish, and floating matters must be deposited.

It is true, we frequently see permanent channels where the forms are extremely different from that which the waters would dig for themselves in an uniform soil, and which approaches a good deal to the trapezium described formerly. We see a greater breadth frequently compensate for a want of depth; but all such deviations are a sort of constraint, or rather are indications of inequality of soil. Such irregular forms are the works of nature; and if they are permanent, the equilibrium is obtained. Commonly the bottom is harder than the sides, consisting of the coarsest of the sand and of gravel; and therefore the necessary section can be obtained only by increasing the width. We are accustomed to attend chiefly to the appearances which prognosticate mischief, and we interpret the appearances of a permanent bed in the same way, and frequently form very false judgments. When we see one bank low and flat, and the other high and abrupt, we suppose that the waters are passing along the first in peace, and with a gentle stream, but that they are rapid on the other side, and are tearing away the bank; but it is just the contrary. The bed being permanent, things are in equilibrium, and each bank is of a form just competent to that equilibrium. If the soil on both sides be uniform, the stream is most rapid

Theory. on that side where the bank is low and flat, for in no other form would it withstand the action of the stream; and it has been worn away till its flatness compensates for the greater force of the stream. The stream on the other side must be more gentle, otherwise the bank could not remain abrupt. In short, in a state of permanency, the velocity of the stream and form of the bank are just suited to each other. It is quite otherwise before the river has acquired its proper regimen.

Necessity of attending to nature in regulating the course of rivers.

A careful consideration therefore of the general features of rivers which have settled their regimen, is of use for informing us concerning their internal motions, and directing us to the most effectual methods of regulating their course.

We have already said that perpendicular brims are inconsistent with stability. A semicircular section is the form which would produce the quickest train of a river whose expense and slope are given; but the banks at B and D (fig. 16) would crumble in, and lie at the bottom, where their horizontal surface would secure them from farther change. The bed will acquire the form GcF, of equal section, but greater width, and with brims less shelving.

Fig. 16.

The proportion of the velocities at A and c may be the same with that of the velocities at A and C; but the velocity at G and F will be less than it was formerly at B, C, or D; and the velocity in any intermediate point E, being somewhat between those at F and c, must be less than it was in any intermediate point of the semicircular bed. The velocities will therefore decrease along the border from c towards G and F, and the steepness of the border will augment at the same time, till, in every point of the new border GcF, these two circumstances will be so adjusted that the necessary equilibrium is established.

The same thing must happen in our trapezium. The slope of the brims may be exact, and will be retained; it will, however, be too great anywhere below, where the velocity is greater, and the sides will be worn away till the banks are undermined and crumble down, and the river will maintain its section by increasing its width. In short, no border made up of straight lines is consistent with that gradation of velocity which will take place whenever we depart from a semicircular form. And we accordingly see, that in all natural channels the section has a curvilinear border, with the slope increasing gradually from the bottom to the brim.

These observations will enable us to understand how nature operates when the inequality of surface or of tenacity obliges the current to change its direction, and the river forms an elbow.

Conditions necessary for a permanent regimen. Supposing always that the discharge continues the same, and that the mean velocity is either preserved or restored, the following conditions are necessary for a permanent regimen.

1. The depth of water must be greater in the elbow than anywhere else.
2. The main stream, after having struck the concave bank, must be reflected in an equal angle, and must then be in the direction of the next reach of the river.
3. The angle of incidence must be proportioned to the tenacity of the soil.
4. There must be in the elbow an increase of slope, or of head of water, capable of overcoming the resistance occasioned by the elbow.

Reasonableness of these conditions. The reasonableness, at least, of these conditions will appear from the following considerations.

1. It is certain that force is expended in producing this change of direction in a channel which by supposition diminishes the current. The diminution arising from any

Theory. cause which can be compared with friction must be greater when the stream is directed against one of the banks. It may be very difficult to state the proportion, and it would occupy too much of our time to attempt it; but it is sufficient that we be convinced that the retardation is greater in this case. We see no cause to increase the mean velocity in the elbow, and we must therefore conclude that it is diminished. But we are supposing that the discharge continues the same; the section must therefore augment, or the channel increase its transverse dimensions. The only question is, In what manner it does this, and what change of form does it affect, and what form is competent to the final equilibrium and the consequent permanency of the bed? Here there is much room for conjecture. Du Buat reasons as follows: If we suppose that the points B and C (fig 17)

Fig. 17.

continue on a level, and that the points H and I at the beginning of the next reach are also on a level, it is an inevitable consequence that the slope along CMI must be greater than along BEH, because the depression of H below B is equal to that of I below C, and BEH is longer than CMI. Therefore the velocity along the convex bank CMI must be greater than along BEH. There may even be a stagnation and an eddy in the contrary direction along the concave bank. Therefore, if the form of the section were the same as up the stream, the sides could not stand on the convex bank. When therefore the section has attained a permanent form, and the banks are again in equilibrio with the action of the current, the convex bank must be much flatter than the concave. If the water is really still on the concave bank, that bank will be absolutely perpendicular, nay, may overhang. Accordingly, this state of things is matter of daily observation, and justifies our reasoning, and entitles us to say, that this is the nature of the internal motion of the filaments which we cannot distinctly observe. The water moves most rapidly along the convex bank, and the thread of the stream is nearest to this side. Reasoning in this way, the section, which we may suppose to have been originally of the form Mb aE (fig 18), assumes the shape MBAE.

Fig. 18.

2. Without presuming to know the mechanism of the internal motions of fluids, we know that superficial waves are reflected precisely as if they were elastic bodies, making the angles of incidence and reflection equal. In as far, therefore, as the superficial wave is concerned in the operation, M. de Buat's second position is just. The permanency of the next reach requires that its axis shall be in the direction of the line EP (fig. 17), which makes the angle GEP = FEN. If the next reach has the direction EQ, MR, the wave reflected in the line ES will work on the bank at S, and will be

Theory. reflected in the line ST, and work again on the opposite bank at T. We know that the effect of the superficial motion is great, and that it is the principal agent in destroying the banks of canals. So far therefore Du Buat is right. We cannot say with any precision or confidence how the actions of the under filaments are modified; but we know no reason for not extending to the under filaments what appears so probable with respect to the surface-water.

3. The third position is no less evident. We do not know the mode of action of the water on the bank; but our general notions on this subject, confirmed by common experience, tell us that the more obliquely a stream of water beats on any bank, the less it tends to undermine it or wash it away. A stiff and cohesive soil therefore will suffer no more from being almost perpendicularly buffeted by a stream than a friable sand would suffer from water gliding along its face. Du Buat thinks, from experience, that a clay bank is not sensibly affected till the angle FEB is about thirty-six degrees.

4. Since there are causes of retardation, and we still suppose that the discharge is kept up, and that the mean velocity, which had been diminished by the enlargement of the section, is again restored, we must grant that there is provided, in the mechanism of these motions, an accelerating force adequate to this effect. There can be no accelerating force in an open stream but the superficial slope. In the present case it is undoubtedly so; because by the deepening of the bottom where there is an elbow in the stream, we have of necessity a counter slope. Now, all this head of water, which must produce the augmentation of velocity in that part of the stream which ranges round the convex bank, will arise from the check which the water gets from the concave bank. This occasions a gorge or swell up the stream, enlarges a little the section at BVC; and this, by the principle of uniform motion, will augment all the velocities, deepen the channel, and put every thing again into its train as soon as the water gets into the next reach. The water at the bottom of this basin has very little motion, but it defends the bottom by this very circumstance.

Remarks
on these
conditions,
and the
reasons of
them.

Such are the notions which Du Buat entertains of this part of the mechanism of running waters. We cannot say that they are very satisfactory, and they are very opposite to the opinions commonly entertained on the subject. Most persons think that the motion is most rapid and turbulent on the side of the concave bank, and that it is owing to this that the bank is worn away till it has become perpendicular, and that the opposite bank is flat, because it has not been gnawed away in this manner. With respect to this general view of the matter, these persons may be in the right; and when a stream is turned into a crooked and yielding channel for the first time, this is its manner of action. But Du Buat's aim is to investigate the circumstances which obtain in the case of a regimen; and in this view he is undoubtedly right as to the facts, though his mode of accounting for these facts may be erroneous. And as this is the only useful view to be taken of the subject, it ought chiefly to be attended to in all our attempts to procure stability to the bed of a river, without the expensive helps of masonry, &c. If we attempt to secure permanency by deepening on the inside of the elbow, our bank will undoubtedly crumble down, diminish the passage, and occasion a more violent action on the hollow bank. The most effectual mean of security is to enlarge the section; and if we do this on the inside bank, we must do it by widening the stream very much, that we may give a very sloping bank. Our attention is commonly drawn to it when the hollow bank is giving way, and with a view to stop the ravages of the stream. Things are not now in a state of permanency, but nature is working in her own way to bring it about. This may not suit *our* purpose, and we must thwart her. The phenomena which we then observe are frequently very unlike to those

described in the preceding paragraphs. We see a violent tumbling motion in the stream towards the hollow bank. We see an evident accumulation of water on that side, and the point B is frequently higher than C. This regorging of the water extends to some distance, and is of itself a cause of greater velocity, and contributes, like a head of stagnant water, to force the stream through the bend, and to deepen the bottom. This is clearly the case when the velocity is excessive, and the hollow bank able to abide the shock. In this situation the water thus heaped up escapes where it best can; and as the water obstructed by an obstacle put in its way escapes by the sides, and there has its velocity increased, so here the water gores up against the hollow bank swells over towards the opposite side, and passes round the convex bank with an increased velocity. It depends much on the adjustment between the velocity and consequent accumulation, and the breadth of the stream and the angle of the elbow, whether this augmentation of velocity shall reach the convex bank; and we sometimes see the motion very languid in that place, and even depositions of mud and sand are made there. The whole phenomena are too complicated to be accurately described in general terms, even in the case of perfect regimen: for this regimen is relative to the consistence of the channel; and when this is very great, the motions may be most violent in every quarter. But the preceding observations are of importance, because they relate to ordinary cases and to ordinary channels.

It is evident from Du Buat's second position, that the proper form of an elbow depends on the breadth of the stream as well as on the radius of curvature, and that every angle of elbow will require a certain proportion between the width of the river and the radius of the sweep. Du Buat gives rules and formulæ for all these purposes, and shows that in one sweep there may be more than one reflection or rebound. It is needless to enlarge on this matter of mere geometrical discussion. It is with the view of enabling the engineer to trace the windings of a river in such a manner that there shall be no rebounds which shall direct the stream against the sides, but preserve it always in the axis of every reach. This is of consequence, even when the bends of the river are to be secured by masonry or piling; for we have seen the necessity of increasing the section, and the tendency which the waters have to deepen the channel on that side where the rebound is made. This tends to undermine our defences, and obliges us to give them deeper and more solid foundations in such places. But any person accustomed to the use of the scale and compasses will form to himself rules of practice equally sure and more expeditious than Du Buat's formulæ.

We proceed, therefore, to what is more to our purpose. Resistance the consideration of the resistance caused by an elbow, and caused by the methods of providing a force capable of overcoming it, an elbow, We have already taken notice of the salutary consequences of over-coming it. arising from the rambling course of rivers, inasmuch as it more effectually spreads them over the face of a country. It is no less beneficial by diminishing their velocity. This it does both by lengthening their course, which diminishes the declivity, and by the very resistance which they meet with at every bend. We derive the chief advantages from our rivers when they no longer shoot their way from precipice to precipice loaded with mud and sand, but peaceably roll along their clear waters, purified during their gentler course, and offer themselves for all the purposes of pasturage, agriculture, and navigation. The more a river winds its way round the foot of the hills, the more is the resistance of its bed multiplied; the more obstacles it meets with in its way from its source to the sea, the more moderate is its velocity; and instead of tearing up the very bowels of the earth, and digging for itself a deep trough, along which it sweeps rocks and rooted-up trees, it flows with majestic

Theory.

Theory. pace even with the surface of our cultivated grounds, which it embellishes and fertilizes.

We may with safety proceed on the supposition, that the force necessary for overcoming the resistance arising from a rebound is as the square of the velocity; and it is reasonable to suppose it proportional to the square of the sine of the angle of incidence, and this for the reasons given for adopting this measure of the general *RESISTANCE of Fluids*. It cannot, however, claim a greater confidence here than in that application; and it has been shown in that article with what uncertainty and limitations it must be received. We leave it to our readers to adopt either this or the simple ratio of the sines, and shall abide by the duplicate ratio with Du Buat, because it appears by his experiments that this law is very exactly observed in tubes in inclinations not exceeding 40°; whereas it is in these small angles that the application to the general resistance of fluids is most in fault. But the correction is very simple if this value shall be found erroneous. There can be no doubt that the force necessary for overcoming the resistance will increase as the number of rebounds. Therefore we may express the resistance, in general, by the formula $r = \frac{n V^2 \sin.^2 I}{m}$;

where r is the resistance, V the mean velocity of the stream, $\sin. I$ the sine of the angle of incidence, n the number of equal rebounds (that is, having equal angles of incidence), and m is a number to be determined by experiment. Du Buat made many experiments on the resistance occasioned by the bendings of pipes, none of which differed from the result of the above formula above one part in twelve; and he concludes, that the resistance to one bend may be estimated at $\frac{V^2 \sin.^2 I}{3000}$. The experiment was in this form. A pipe of one

inch diameter, and ten feet long, was formed with ten rebounds of 36° each. A head of water was applied to it, which gave the water a velocity of six feet per second. Another pipe of the same diameter and length, but without any bendings, was subjected to a pressure of a head of water, which was increased till the velocity of efflux was also six feet per second. The additional head of water was $5\frac{9}{10}$ inches. Another of the same diameter and length, having one bend of 24° 34', and running eighty-five inches per second, was compared with a straight pipe having the same velocity, and the difference of the heads of water was $\frac{27}{100}$ of an inch. A computation from these two experiments will give

the above result, or, in English measure, $r = \frac{V^2 \sin.^2 I}{3200}$ very

nearly. It is probable that this measure of the resistance is too great; for the pipe was of uniform diameter even in the bends: whereas, in a river properly formed, where the regimen is exact, the capacity of the section of the bend is increased.

Theory applied to inclined tubes and open streams. The application of this theory to inclined tubes and to open streams is very obvious, and very legitimate and safe. Let AB (fig. 19) be the whole height of the reservoir A B I K, and BC the horizontal length of a pipe, containing any number of rebounds, equal or unequal, but all regular, that is, constructed according to the conditions formerly mentioned. The whole head of water should be conceived as performing, or as divided into portions which perform, three different offices. One portion,

$AD = \frac{V^2}{509}$, impels the water in-

to the entry of the pipe with the velocity with which it really moves in it; another portion EB is in equilibrio with the resistances arising from the mere length of the pipe ex-

Fig. 19.

panded into a straight line; and the third portion DE serves to overcome the resistance of the bends. If, therefore, we draw the horizontal line BC, and, taking the pipe BC out of its place, put it in the position DH, with its mouth C in H, so that DH is equal to BC, the water will have the same velocity in it that it had before. For greater simplicity of argument, we may suppose that when the pipe was inserted at B, its bends lay all in a horizontal plane, and that when it is inserted at D, the plane in which all its bends lie slopes only in the direction DH, and is perpendicular to the plane of the figure. We repeat it, the water will have the same velocity in the pipes BC and DH, and the resistances will be overcome. If we now prolong the pipe DH towards L to any distance, repeating continually the same bendings in a series of lengths, each equal to DH, the motion will be continued with the velocity corresponding to the pressure of the column AD; because the declivity of the pipe is augmented in each length equal to DH, by a quantity precisely sufficient for overcoming all the resistances in that length; and the true slope in these cases is BE + ED, divided by the expanded length of the pipe BC or DH.

The analogy which we were enabled to establish between the uniform motion or the train of pipes and of open streams, entitles us now to say, that when a river has bendings, which are regularly repeated at equal intervals, its slope is compounded of the slope which is necessary for overcoming the resistance of a straight channel of its whole expanded length, agreeably to the formula for uniform motion, and of the slope which is necessary for overcoming the resistance arising from its bending alone.

Thus, let there be a river which, in the expanded course of 6000 fathoms, has 10 elbows, each of which has 30° of rebound; and let its mean velocity be 20 inches in a second. If we should learn its whole slope in this 6000 fathoms, we must first find (by the formula of uniform motion) the slope s which will produce the velocity of 20 inches in a straight river of this length, section, and mean depth. Suppose this to be $\frac{1}{21600}$, or 20 inches, in this whole

length. We must then find by the formula $\frac{n V^2 \sin.^2 I}{3200}$ the slope necessary for overcoming the resistance of ten rebounds of 30° each. This we shall find to be $6\frac{2}{3}$ inches in the 6000 fathoms. Therefore the river must have a slope of $26\frac{2}{3}$ inches in 6000 fathoms, or $\frac{1}{16200}$; and this slope will produce the same velocity which 20 inches, or $\frac{1}{21600}$, would do in a straight-running river of the same length.

PART II.—PRACTICAL INFERENCES.

Having thus established a theory of a most important part of hydraulics, which may be confided in as a just representation of nature's procedure, we shall apply it to the examination of the chief results of every thing which art has contrived for limiting the operations of nature, or modifying them so as to suit our particular views. Trusting to the detail which we have given of the connecting principles, and the chief circumstances which co-operate in producing the ostensible effect; and supposing that such of our readers as are interested in this subject will not think it too much trouble to make the applications in the same detail; we shall content ourselves with merely pointing out the steps of the process, and showing their foundation in the theory itself; and frequently, in place of the direct analysis which the theory enables us to employ for the solution of the problems, we shall recommend a process of approximation by trial and correction, sufficiently accurate, and more within the reach of practical engineers.

Practical Inferences. We are naturally led to consider in order the following articles.

1. The effects of permanent additions of every kind to the waters of a river, and the most effectual methods of preventing or removing inundations.

2. The effects of weirs, bars, sluices, and keeps of every kind, for raising the surface of a river; and the similar effects of bridges, piers, and every thing which contracts the section of the stream.

3. The nature of canals; how they differ from rivers in respect of origin, discharge, and regimen, and what conditions are necessary for their most perfect construction.

4. Canals for draining land, and drafts or canals of derivation from the main stream. The principles of their construction, so that they may suit their intended purposes; and the change which they produce on the main stream, both above and below the point of derivation.

Of the Effects of Permanent Additions to the Waters of a River.

From what has already been said, it appears that to every kind of soil or bed there corresponds a certain velocity of current, too small to hurt it by digging it up, and too great to allow the deposition of the materials which it is carrying along. Supposing this known for any particular situation, and the quantity of water which the channel must of necessity discharge, we may wish to learn the smallest slope which must be given to this stream, that the waters may run with the required velocity. This suggests,

PROB. I.¹ Given the discharge D of a river, and V its velocity of regimen: required the smallest slope s , and the dimensions of its bed.

Since the slope must be the smallest possible, the bed must have the form which will give the greatest mean depth d , and should therefore be the trapezium formerly described; and its area and perimeter are the same with those of a rectangle whose breadth is twice its height h .

These circumstances gives us the equation $\frac{D}{V} = 2h^2$. For the area of the section is twice the square of the height, and the discharge is the product of this area and the velocity. Therefore $\sqrt{\frac{D}{2V}} = h$ and $\sqrt{\frac{2D}{V}} =$ the breadth b .

The formula of uniform motion gives $\sqrt{s} - L\sqrt{s+1.6} = \frac{297(\sqrt{d}-0.1)}{V+0.3(\sqrt{d}-0.1)}$. Instead of $\sqrt{d}-0.1$, put its equal

$\sqrt{\frac{h}{2}}-0.1$, and every thing being known in the second side of this equation, we easily get the value of s by a few trials after the following manner: Suppose that the second side is equal to any number, such as 9. First suppose that \sqrt{s} is = 9, whence $s = 81$. Then the hyperbolic logarithm of $\sqrt{81+1.6}$ or $\sqrt{82.6}$ is 2.21. Therefore we have $\sqrt{s} - L\sqrt{s+1.6} = 9 - 2.21 = 6.79$; whereas it should have been = 9. Therefore say $6.79 : 9 = 9 : 11.9$ nearly. Now suppose that \sqrt{s} is = 11.9, whence $s = 141.6$. Then $L\sqrt{141.6+1.6} = L\sqrt{143.2} = 2.482$ nearly, and $11.9 - 2.482 = 9.408$, whereas it should be 9. Now we find that changing the value of \sqrt{s} from 9 to 11.9 has changed the answer from 6.79 to 9.408, or a change of 2.9 in our assumption has made a change of 2.618 in the answer, and has left an error of 0.408. Therefore say $2.618 : 0.408 = 2.9 : 0.452$. Then taking 0.452 from 11.9, we have, for our next assumption, or value of \sqrt{s} , 11.448, whence $s = 131.1$. Now 131.1

+ 1.6 = 132.7, and $L\sqrt{132.7} = 2.444$ nearly, and $11.448 - 2.444 = 9.004$ in place of 9, whence it is inferred that this last value of $\sqrt{s} = 11.448$ is sufficiently exact. This may serve as a specimen of the trials by which we may avoid an intricate analysis.

PROB. II. Given the discharge D , the slope s , and the velocity V , of permanent regimen, to find the dimensions of the bed.

Let x be the width and y the depth of the channel, and S the area of the section. This must be $= \frac{D}{V}$, which is

therefore $= xy$. The denominator s being given, we may make $\sqrt{s} - L\sqrt{s+1.6} = \sqrt{B}$, and the formula of mean velocity will give $V = \frac{297(\sqrt{d}-0.1)}{\sqrt{B}} - 0.3(\sqrt{d}-0.1)$,

which we may express thus: $V = (\sqrt{d}-0.1)\left(\frac{297}{\sqrt{B}}-0.3\right)$,

which gives $\frac{V}{\frac{297}{\sqrt{B}}-0.3} = (\sqrt{d}-0.1)$; and, finally, $\frac{V}{\frac{297}{\sqrt{B}}-0.3} + 0.1 = \sqrt{d}$.

Having thus obtained what we call the mean depth, we may suppose the section rectangular. This gives $d = \frac{xy}{x+2y}$.

Thus we have two equations, $S = xy$ and $d = \frac{xy}{x+2y}$.

From which we obtain $x = \sqrt{\left(\frac{S}{2d}\right)^2 - 2S} + \frac{S}{2d}$. And

having the breadth x and area S , we have $y = \frac{S}{x}$. And then we may change this for the trapezium often mentioned.

These are the chief problems on this part of the subject, and they enable us to adjust the slope and channel of a river which receives any number of successive permanent additions by the influx of other streams. This last informs us of the rise which a new supply will produce, because the additional supply will require additional dimensions of the channel; and as this is not supposed to increase in breadth, the addition will be in depth. The question may be proposed in the following problem.

PROB. III. Given the slope s , the depth and the base of a rectangular bed (or a trapezium), and consequently the discharge D , to find how much the section will rise if the discharge be augmented by a given quantity.

Let h be the height after the augmentation, and w the width for the rectangular bed. We have in any uniform

current $\sqrt{d} = \frac{V}{\frac{297}{\sqrt{B}}-0.3} + 0.1$. Raising this to a square,

and putting for d and V their values $\frac{wh}{w+2h}$ and $\frac{D}{w+2h}$, and making $\frac{297}{\sqrt{B}} - 0.3 = K$, the equation becomes $\frac{wh}{w+2h} = \left(\frac{D}{whK} + 0.1\right)^2$. Raising the second member to a square,

and reducing, we obtain a cubic equation, to be solved in the usual manner.

But the solution would be extremely complicated. We may obtain a very expeditious and exact approximation from this consideration, that a small change in one of the dimensions of the section will produce a much greater change in the section and the discharge than in the mean

¹ In these problems and examples the measures are expressed in French inches. For English inches the co-efficient 307 must be used in place of 297.

Practical Inferences. depth d . Having therefore augmented the unknown dimension, which is here the height, make use of this to form a new mean depth, and then the new equation

$$\sqrt{d} = \frac{D}{w h \left(\frac{297}{\sqrt{B}} - 0.3 \right)} + 0.1 \text{ will give us another value of } h,$$

which will rarely exceed the truth by $\frac{1}{10}$. This serves (by the same process) for finding another, which will commonly be sufficiently exact. We shall illustrate this by an example.

Let there be a river whose channel is a rectangle 150 feet wide and six feet deep, and which discharges 1500 cubic feet of water per second, having a velocity of twenty inches, and slope of $\frac{1}{12} \frac{1}{660}$, or about $\frac{7}{12}$ of an inch in 100 fathoms. How much will it rise if it receives an addition which triples its discharge? and what will be its velocity?

If the velocity remained the same, its depth would be tripled; but we know by the general formula that its velocity will be greatly increased, and therefore its depth will not be tripled. Suppose it to be doubled, and to become twelve feet. This will give $d = 10.34483$, or 124.138

inches; then the equation $\sqrt{d} - 0.1 = \frac{D}{w h \left(\frac{297}{\sqrt{B}} - 0.3 \right)}$, or

$$h = \frac{D}{w (\sqrt{d} - 0.1) \left(\frac{297}{\sqrt{B}} - 0.3 \right)}, \text{ and in which we have}$$

$\sqrt{B} = 107.8$, $D = 4500 \times 1728 = 7776000$ cubic inches, $w = 1800$ inches, $\sqrt{d} - 0.1 = 11.0417$, will give $h = 159.33$ inches or 13.276 feet; whereas it should have been 12. This shows that our calculated value of d was too small. Let us therefore increase the depth by 0.9, or make it 12.9, and repeat the calculation. This will give us $\sqrt{d} - 0.1 = 11.3927$, and $h = 12.867$, instead of 13.276. Therefore, augmenting our data, 0.9 changes our answer 0.409. If we suppose these small changes to retain their proportions, we may conclude that if 12 be augmented by the quantity $x \times 0.9$, the quantity 13.276 will diminish by the quantity $x \times 0.409$. Therefore, that the estimated value of h may agree with the one which results from the calculation, we must have $12 + x \times 0.9 = 13.276 - x \times 0.409$. This will give $x = \frac{1.276}{1.309} = 0.9748$; and $x \times 0.9 = 0.8773$; and $h = 12.8773$. If we repeat the calculation with this value of h , we shall find no change.

This value of h gives $d = 131.8836$ inches. If we now compute the new velocity by dividing the new discharge 4500 by the new area 150×12.8773 , we shall find it to be 27.95 inches, in place of 20, the former velocity.

We might have made a pretty exact first assumption, by recollecting what was formerly observed, that when the breadth is very great in proportion to the depth, the mean depth differs insensibly from the real depth, or rather follows nearly the same proportions, and that the velocities are proportional to the square roots of the depths. Call the first discharge d , the height h , and velocity v , and let D , H , and V , express these things in their augmented state. We have $v = \frac{d}{w h}$ and $V = \frac{D}{w H}$, and $v : V = \frac{d}{h} : \frac{D}{H}$,

$$\text{and } v^2 : V^2 = \frac{d^2}{h^2} : \frac{D^2}{H^2}. \text{ But by this remark } v^2 : V^2 = h : H.$$

$$\text{Therefore } h : H = \frac{d^2}{h^2} : \frac{D^2}{H^2}, \text{ and } \frac{h D^2}{H^2} = \frac{H d^2}{h^2}, \text{ and } h^3 D^2 = H^3 d^2,$$

$$\text{and } d^2 : D^2 = h^3 : H^3 \text{ (a useful theorem), and } H^3 = \frac{h^3 D^2}{d^2}$$

$$\text{and } H = \sqrt[3]{\frac{h^3 D^2}{d^2}} = 12.48.$$

Or we might have made the same assumption by the re- Practical mark also formerly made on this case, that the squares of Inferences. the discharges are nearly as the cubes of the heights, or $1500^2 : 4500^2 = 6^3 : 12.48^3$.

And in making these first guesses, we shall do it more exactly, by recollecting that a certain variation of the mean depth d requires a greater variation of the height, and the increment will be to the height nearly as half the height to the width, as may easily be seen. Therefore, if we add

to 12.48 its $\frac{6.24}{150}$ th part, or its 24th part, viz. 0.52, we have

13 for our first assumption, exceeding the truth only an inch and a half. We mention these circumstances, that those who are disposed to apply these doctrines to the solution of practical cases may be at no loss when one occurs of which the regular solution requires an intricate analysis.

It is evident that the inverse of the foregoing problems The in- will show the effects of enlarging the section of a river, verse of that is, will show how much its surface will be sunk by any the problems proposed enlargement of its bed. It is therefore needless to propose such problems in this place. Common sense shows the effects of enlarging directs us to make these enlargements in those parts of the river where their effect will be greatest, that is, where it is the section shallowest when its breadth greatly exceeds its depth, or of the river, where it is narrowest (if its depth exceed the breadth, which is a very rare case), or, in general, where the slope is the smallest for a short run.

The same general principles direct us in the method of and directs embankments for the prevention of floods, by enabling us us in the to ascertain the heights necessary to be given to our banks. method of This will evidently depend, not only on the additional embank- quantity of water which experience tells us a river brings down during its freshes, but also on the distance at which we place the banks from the natural banks of the river. This is a point where mistaken economy frequently defeats its own purpose. If we raise our embankment at some distance from the natural banks of the river, not only will a smaller height suffice, and consequently a smaller base, which will make a saving in the duplicate proportion of the height; but our works will be so much the more durable nearly, if not exactly, in the same proportion. For by thus enlarging the additional bed which we give to the swollen river, we diminish its velocity almost in the same proportion that we enlarge its channel, and thus diminish its power of ruining our works. Except, therefore, in the case of a river whose freshes are loaded with fine sand to destroy the turf, it is always proper to place the embankment at a considerable distance from the natural banks. Placing them at half the breadth of the stream from its natural banks, will nearly double its channel; and, except in the case here mentioned, the space now detached from our fields will afford excellent pasture.

The limits of such a work as ours will not permit us to enter into any detail on the method of embankment. It would require a volume to give instructions as to the manner of founding, raising, and securing the dikes which must be raised, and a thousand circumstances which must be attended to. But a few general observations may be made, which naturally occur while we are considering the manner in which a river works in settling or altering its channel.

It must be remarked, in the first place, that the river will rise higher when embanked than it does while it was allowed to spread; and it is by that means easy to conclude to what height it will rise from the greatest height to which it has been observed to rise in its floods. When at liberty to expand over a wide valley, then it could only rise till it overflowed with a thickness or depth of water sufficient to produce a motion backwards into the valley

Practical Inferences. quick enough to take off the water as fast as it was supplied; and we imagine that a foot or two would suffice in most cases. The best way for a prudent engineer will be to observe the utmost rise remembered by the neighbours in some gorge, where the river cannot spread out. Measure the increased section in this place, and at the same time recollect that the water increases in a much greater proportion than the section; because an increase of the hydraulic mean depth produces an increase of velocity in nearly the duplicate proportion of the depth. But as this augmentation of velocity will also obtain between the embankments, it will be sufficiently exact to suppose that the section must here be increased nearly in the same proportion as at the gorge already mentioned. Neglecting this method of information, and regulating the height of our embankments by the greatest swell that has been observed in the plain, will assuredly make them too low, and render them totally useless.

A line of embankment should always be carried on by a strict concert of the proprietors of both banks through its whole extent. A greedy proprietor, by advancing his own embankment beyond that of his neighbours, not only exposes himself to risk by the working of the waters on the angles which this will produce, but exposes his neighbours also to danger, by narrowing the section, and thereby raising the surface and increasing the velocity, and by turning the stream athwart, and causing it to shoot against the opposite bank. The whole should be as much as possible in a line; and the general effect should be to make the course of the stream straighter than it was before. All bends should be made more gentle, by keeping the embankment farther from the river in all convex lines of the natural bank, and bringing it nearer where the bank is concave. This will greatly diminish the action of the waters on the embankment, and insure their duration. The same maxim must be followed in fencing any brook which discharges itself into the river. The bends given at its mouth to the two lines of embankment should be made less acute than those of the natural brook, although by this means two points of land are left out. And the opportunity should be embraced of making the direction of this transverse brook more sloping than before, that is, less athwart the direction of the river.

It is of great consequence to cover the outside of the dike with very compact turf closely united. If it admit water, the interior part of the wall, which is always more porous, becomes drenched in water, and this water acts with its statical pressure, tending to burst the bank on the land side, and will quickly shift it from its seat. The utmost care should therefore be taken to make it and keep it perfectly tight. It should be a continued fine turf, and every bare spot should be carefully covered with fresh sod and rat-holes must be carefully closed up.

Of Straighting or Changing the Course of Rivers.

Of the slope required at the bend of a river, and the consequences. We have seen that every bending of a river requires an additional slope in order to continue its train, or enable it to convey the same quantity of water without swelling in its bed. The effect of taking away any of these bends must be to sink the waters of the river. It is proper, therefore, to have it in our power to estimate these effects. It may be desirable to gain property by taking away the sweeps of a very winding stream; but this may be prejudicial, by destroying the navigation on such a river. It may also hurt the proprietors below, by increasing the velocity of the stream, which will expose them to the risk of its overflowing, or of its destroying its bed, and taking a new course. Or this increase of velocity may be inconsistent with the regimen of the new channel, or at least require larger dimensions than we should have given it if ignorant of this effect.

Our principles of uniform motion enable us to answer

every question of this kind which can occur; and Du Buat proposes several problems to this effect. The regular solutions of them are complicated and difficult; and we do not think them necessary in this place, because they may all be solved in a manner not indeed so elegant, because indirect, but abundantly accurate, and easy to any person familiar with those which we have already considered.

We can take the exact level across all these sweeps, and thus obtain the whole slope. We can measure with accuracy the velocity in some part of the channel which is most remote from any bend, and where the channel itself has the greatest regularity of form. This will give us the expense or discharge of the river, and the mean depth connected with it. We can then examine whether this velocity is precisely such as is compatible with stability in the straight course. If it is, it is evident that if we cut off the bends, the greater slope which this will produce will communicate to the waters a velocity incompatible with the regimen suited to this soil, unless we enlarge the width of the stream, that is, unless we make the new channel more capacious than the old one. We must now calculate the dimensions of the channel which, with this increased slope, will conduct the waters with the velocity that is necessary. All this may be done by the foregoing problems; and we may accomplish this most easily by steps. First, suppose the bed the same with the old one, and calculate the velocity for the increased slope by the general formula. Then change one of the dimensions of the channel, so as to produce the velocity we want, which is a very simple process. And in doing this, the object to be kept chiefly in view is not to make the new velocity such as will be incompatible with the stability of the new bed.

Having accomplished this first purpose, we learn, in the very solution, how much shallower this channel with its greater slope will be than the former, while it discharges all the waters. This diminution of depth must increase the slope and the velocity, and must diminish the depth of the river above the place where the alteration is to be made. How far it produces these effects may be calculated by the general formula. We then see whether the navigation will be hurt, either in the old river up the stream, or in the new channel. It is plain that all these points cannot be reconciled. We may make the new channel such, that it shall leave a velocity compatible with stability, and that it shall not diminish the depth of the river up the stream. But having a greater slope, it must have a smaller mean depth, and also a smaller real depth, unless we make it of a very inconvenient form.

The same things viewed in a different light, will show us what depression of waters may be produced by rectifying the course of a river in order to prevent its overflowing. And the process which we would recommend is the same with the foregoing. We apprehend it to be quite needless to measure the angles of rebound, in order to compute the slope which is employed for sending the river through the bend, with a view to supersede this by straightening the river. It is infinitely easier and more exact to measure the levels themselves, and then we know the effect of removing them.

Nor need we follow Du Buat in solving problems for diminishing the slope and velocity, and deepening the channel of a river by bending its course. The expense of this would in every case be enormous; and the practices which we are about to discuss afford infinitely easier methods of accomplishing all the purposes which are to be gained by these changes.

Of Bars, Weirs, and Jetties, for raising the Surface of Rivers.

We propose, under the article WATER-WORKS, to consider in sufficient practical detail all that relates to the construction and mechanism of these and other erections

Practical Inferences.

Practical Inferences. in water; and we confine ourselves, in this place, to the mere effect which they will produce on the current of the river.

Problems, examples, and consequences of raising the surface of rivers. We gave the name of *weir* or *bar* to a dam erected across a river for the purpose of raising its waters, whether in order to take off a draft for a mill or to deepen the channel. Before we can tell the effect which they will produce, we must have a general rule for ascertaining the relation between the height of the water above the lip of the weir or bar, and the quantity of water which will flow over.

First, then, with respect to a weir, represented in fig. 20 and fig. 21. The latter figure more resembles their usual

Fig. 20.

Fig. 21.

form, consisting of a dam of solid masonry, or built of timber, properly fortified with shoars and banks. On the top is set up a strong plank FR, called the wasteboard or waster, over which the water flows. This is brought to an accurate level, of the proper height. Such voiders are frequently made in the side of a mill-course, for letting the superfluous water run off. This is properly the *WASTER*, or *VOIDER*: it is also called an *OFFSET*. The same observations will explain all these different pieces of practice. The following questions occur in course.

PROB. I. Given the length of an offset or wasteboard made in the face of a reservoir of stagnant water, and the depth of its lip under the horizontal surface of the water, to determine the discharge, or the quantity of water which will run over, in a second.

Let AB be the horizontal surface of the still water, and F the lip of the wasteboard. Call the depth BF under the surface h , and the length of the wasteboard l . The water is supposed to flow over into another basin or channel, so much lower that the surface HL of the water is lower, or at least not higher, than F.

If the water could be supported at the height BF, BF might be considered as an orifice in the side of a vessel. In this case, the discharge would be the same as if the whole water were flowing with the velocity acquired from the height $\frac{1}{2}BF$, or $\frac{1}{2}h$. And if we suppose that there is no contraction at the orifice, the mean velocity would be $\sqrt{2g \times \frac{1}{2}h} = \sqrt{772 \times \frac{1}{2}h}$, in English inches, per second. The area of this orifice is lh . Therefore the discharge would be $lh \sqrt{772 \times \frac{1}{2}h}$, all being measured in inches. This is the usual theory; but it is not an exact representation of the manner in which the efflux really happens. The water cannot remain at the height BF; but in drawing towards the wasteboard from all sides it forms a convex surface AIH, so that the point I, where the vertical drawn from the edge of the wasteboard meets the curve, is considerably lower than B. But as all the mass above F is supposed perfectly fluid, the pressure of the incumbent water is propagated, in the opinion of Du Buat, to the filament passing over at F without any diminution. The same may be said of any filament between F and I. Each tends, therefore, to move in the same manner as if it were really impelled through an orifice in its place. Therefore the motions through every part of the line or plane IF are the same as if the water were escaping through an orifice IF, made by a sluice let down on the water, and keeping up the water of the reservoir to the level AB. It is beyond a doubt, says he, that the height IF must depend on the whole

height BF, and that there must be a certain determined proportion between them. He does not attempt to determine this proportion theoretically, but says that his experiments ascertain it with great precision to be the proportion of one to two, or that IF is always one half of BF. He says, however, that this determination was not by an immediate and direct measurement; he concluded it from the comparison of the quantities of water discharged under different heights of the water in the reservoir.

We cannot help thinking that this reasoning is very defective in several particulars. It cannot be inferred, from the laws of hydrostatical pressure, that the filament at I is pressed forward with all the weight of the column BI. The particle I is really at the surface; and considering it as making part of the surface of a running stream, it is subjected to hardly any pressure, any more than the particles on the surface of a cup of water held in the hand, while it is carried round the axis of the earth and round the sun. Reasoning according to his own principles, and availing himself of his own discovery, he should have said that the particle at I has an accelerating force depending on its slope only; and then he should have endeavoured to ascertain this slope. The motion of the particle at I has no immediate connection with the pressure of the column BI; and if it had, the motion would be extremely different from what it is; for this pressure alone would give it the velocity which Du Buat assigns it. Now it is already passing through the point I with the velocity which it has acquired in descending along the curve AI; and this is the real state of the case. The particles are passing through with a velocity already acquired by a sloping current; and they are accelerated by the hydrostatical pressure of the water above them. The internal mechanism of these motions is infinitely more complex than Du Buat here supposes; and on this supposition, he very nearly abandons the theory which he has so ingeniously established, and adopts the theory of Guglielmini, which he had exploded. At the same time, we think that he is not much mistaken when he asserts that the motions are nearly the same as if a sluice had been let down from the surface to I. For the filament which passes at I has been gliding down a curved surface, and has not been exposed to any friction. It is perhaps the very case of hydraulics where the obstructions are the smallest; and we should therefore expect that its motion will be least retarded.

We have therefore no hesitation in saying, that the filament at I is in the very state of motion which the theory would assign to it if it were passing under a sluice, as Du Buat supposes. And with respect to the inferior filaments, without attempting the very difficult task of investigating their motions, we shall just say, that we do not see any reason for supposing that they will move slower than our author supposes. Therefore, though we reject his theory, we admit his experimental proposition in general; that is, we admit that the whole water which passes through the plane IF moves with the velocity (though not in the same direction) with which it would have run through a sluice of the same depth; and we may proceed with his determination of the quantity of water discharged.

If we make BC the axis of a parabola BEGK, the velocities of the filaments passing at I and F will be represented by the ordinates IE and FG, and the discharge by the area IEGF. This allows a very neat solution of the problem. Let the quantity discharged per second be D, and let the whole height BF be h . Let $2G$ be the quantity by which we must divide the square of the mean velocity in order to have the producing height. This will be less than $2g$, the acceleration of gravity, on account of the convergency at the sides and the tendency to convergence at the lip F. We formerly gave for its measure 702 inches, instead of 772, and said that the inches discharged per second from an orifice of one inch were 26.49, instead of 27.79.

Practical Inferences. Let x be the distance of any filament from the horizontal line AB. An element of the orifice, therefore (for we may give it this name), is ldx . The velocity of this element is $\sqrt{2Gx}$, or $\sqrt{2G} \times x^{\frac{1}{2}}$. The discharge from it is $l\sqrt{2G} x^{\frac{1}{2}} dx$, and the integral of this differential or $D = \int l\sqrt{2G} x^{\frac{1}{2}} dx$

$= \frac{2}{3} l\sqrt{2G} x^{\frac{3}{2}} + C$. To determine the constant quantity C , observe that Du Buat found by experiment that IF was in all cases $\frac{1}{2}$ BF. Therefore D must be nothing when $x = \frac{1}{2} h$; consequently $C = -\frac{2}{3} l\sqrt{2G} \left(\frac{h}{2}\right)^{\frac{3}{2}}$, and the complete integral will be $D = \frac{2}{3} l\sqrt{2G} \left[x^{\frac{3}{2}} - \left(\frac{h}{2}\right)^{\frac{3}{2}} \right]$.

Now make $x = h$, and we have

$$D = \frac{2}{3} l\sqrt{2G} \left[h^{\frac{3}{2}} - \left(\frac{h}{2}\right)^{\frac{3}{2}} \right] = \frac{2}{3} l\sqrt{2G} \left[1 - \left(\frac{1}{2}\right)^{\frac{3}{2}} \right] h^{\frac{3}{2}}.$$

But $1 - \left(\frac{1}{2}\right)^{\frac{3}{2}} = 0.64645$, and $\frac{2}{3}$ of this is 0.431. Therefore, finally, $D = 0.431 l\sqrt{2G} h^{\frac{3}{2}}$.

If we now put 26.49 or $26\frac{1}{2}$ for $\sqrt{2G}$, or the velocity with which a head of water of one inch will impel the water over a weir, and multiply this by 0.431, we get the following quantity, 11.4172, or, in numbers of easy recollection, $11\frac{1}{2}$, for the cubic inches of water per second, which runs over every inch of a wasteboard when the edge of it is one inch below the surface of the reservoir; and this must be multiplied by $h^{\frac{3}{2}}$, or by the square root of the cube of the head of water. Thus, let the edge of the wasteboard be four inches below the surface of the water. The cube of this is 64, of which the square root is eight. Therefore a wasteboard of this depth under the surface, and three feet long, will discharge every second $8 \times 36 \times 11\frac{1}{2}$ cubic inches of water, or $1\frac{1}{2}$ cubic feet, English measure.

The following comparisons will show how much this theory may be depended on. The first column shows the depth of the edge of the board under the surface, the second shows the discharge by theory, and the third the discharge actually observed. The length of the board was 18.4 inches. The numbers in Du Buat's experiments are here reduced to English measure.

D.	D. Theor.	D. Exp.	F.
1.778	506	524	28.5
3.199	1222	1218	66.2
4.665	2153	2155	117.1
6.753	3750	3771	204.9

The last column is the cubic inches discharged in a second by each inch of the wasteboard. The correspondence is undoubtedly very great. The greatest error is in the first, which may be attributed to a much smaller lateral contraction under so small a head of water.

But it must be remarked, that the calculation proceeds on two suppositions. The height FI is supposed $\frac{1}{2}$ of BI; and $2G$ is supposed 702. It is evident, that by increasing the one and diminishing the other, nearly the same answers may be produced, unless much greater variations of h be examined. Both of these quantities are matters of considerable uncertainty, particularly the first; and it must be farther remarked, that this was not measured, but deduced from the uniformity of the experiments. We presume that Du Buat tried various values of G , till he found one which gave the ratios of discharge which he observed. We beg leave to observe, that in a set of numerous experiments which we had access to examine, BI was uniformly much less than $\frac{1}{2}$; it was very nearly $\frac{2}{3}$; and the quantity discharged was greater than what would result from Du Buat's calculation. It was further observed that IF depended very

much on the form of the wasteboard. When it was a very thin board of considerable depth, IF was very considerably greater than if the board was thick, or narrow, and set on the top of a broad dam-head, as in fig. 21.

It may be proper to give the formula a form which will correspond to any ratio which experience may discover be-

tween BF and IF. Thus, let IF be $\frac{m}{n}$ BF. The formula

$$\text{will be } D = \frac{2}{3} l\sqrt{2G} \left(1 - \left(\frac{m}{n}\right)^{\frac{3}{2}} \right) h^{\frac{3}{2}}.$$

Meantime this theory of Du Buat is of great value to the practical engineer, who at present must content himself with a very vague conjecture, or take the calculation of the erroneous theory of Guglielmini. By that theory, the board of three feet, at the depth of four inches, should discharge nearly $3\frac{1}{2}$ cubic feet per second, which is almost double of what it really delivers.

We presume, therefore, that the following table will be acceptable to practical engineers, who are not familiar with such computations. It contains, in the first column, the depth in English inches from the surface of the stagnant water of a reservoir to the edge of the wasteboard. The second column is the cubic feet of water discharged in a minute by every inch of the wasteboard.

Depth.	Discharge.	Depth.	Discharge.
1.....	0.403	10.....	12.718
2.....	1.140	11.....	14.707
3.....	2.095	12.....	16.758
4.....	3.225	13.....	18.895
5.....	4.507	14.....	21.117
6.....	5.925	15.....	23.419
7.....	7.466	16.....	25.800
8.....	9.122	17.....	28.258
9.....	10.884	18.....	30.786

When the depth does not exceed four inches, it will not be exact enough to take proportional parts for the fractions of an inch. The following method is exact.

If they be odd quarters of an inch, look in the table for as many inches as the depth contains quarters, and take the eighth part of the answer. Thus, for $3\frac{1}{4}$ inches, take the eighth part of 23.419, which corresponds to 15 inches. This is 2.927.

If the wasteboard is not on the face of a dam, but in a running stream, we must augment the discharge by multiplying the section by the velocity of the stream. But this correction can seldom occur in practice; because in this case the discharge is previously known, and it is h that we want, which is the object of the next problem.

We only beg leave to add, that the experiments which we mention as having been already made in this country, give a result somewhat greater than this table, viz. about $\frac{1}{16}$. Therefore, having obtained the answer by this table, add to it its 16th part, and we apprehend that it will be extremely near the truth.

When, on the other hand, we know the discharge over a wasteboard, we can tell the depth of its edge under the surface of the stagnant water of the reservoir, because we have $h = \left(\frac{D}{11\frac{1}{2}l} \right)^{\frac{2}{3}}$ very nearly.

We are now in a condition to solve the problem respecting a weir across a river.

PROB. II. The discharge and section of a river being given, it is required to determine how much the water will be raised by a weir of the whole breadth of the river, discharging the water with a clear fall, that is, the surface of the water in the lower channel being below the edge of the weir.

In this case we have $2G = 131$ nearly, because there

Practical will be no contraction at the sides when the weir is the whole breadth of the river. But, further, the water is not now stagnant, but moving with the velocity $\frac{D}{S}$, S being the section of the river.

Therefore let a be the height of the weir from the bottom of the river, and h the height of the water above the edge of the weir. We have the velocity with which the water approaches the weir $= \frac{D}{l(a+h)}$, l being the length of the weir or breadth of the river. Therefore the height producing the primary mean velocity is $\left(\frac{D}{l\sqrt{2g}(a+h)}\right)^2$.

The equation given a little ago will give $h = \left(\frac{D}{0.431 l\sqrt{2g}}\right)^{\frac{2}{3}}$, when the water above the weir is stagnant. Therefore, when it is already moving with the velocity $\frac{D}{l(a+h)}$, we shall have $h = \left(\frac{D}{0.431 l\sqrt{2g}}\right)^{\frac{2}{3}} - \left(\frac{D}{l\sqrt{2g}(a+h)}\right)^2$. It would be

very troublesome to solve this equation regularly, because the unknown quantity h is found in the second term of the answer. But we know that the height producing the velocity above the weir is very small in comparison of h and of a , and, if only estimated roughly, will make a very insensible change in the value of h ; and, by repeating the operation, we can correct this value, and obtain h to any degree of exactness.

To illustrate this by an example. Suppose a river, the section of whose stream is 150 feet, and that it discharges 174 cubic feet of water in a second; how much will the waters of this river be raised by a weir of the same width, and 3 feet high.

Suppose the width to be 50 feet. This will give 3 feet for the depth; and we see that the water will have a clear fall, because the lower stream will be the same as before.

The section being 150 feet, and the discharge 174, the mean velocity is $\frac{174}{150} = 1.16$ feet = 14 inches nearly, which requires the height of $\frac{1}{4}$ of an inch very nearly. This may be taken for the second term of the value of h . Therefore

$h = \left(\frac{D}{0.431 l\sqrt{2g}}\right)^{\frac{2}{3}} - \frac{1}{4}$. Now $\sqrt{2g}$ is, in the present case, 27.03, l is 600, and D is $174 \times 1728 = 300672$. Therefore $h = 12.28 - 0.25 = 12.03$ nearly. Correct this value by substituting a more accurate value of the second term $\left(\frac{D}{l\sqrt{2g}(a+h)}\right)^2$, or 0.14. This will give us $h = 12.28 - 0.25 = 12.03$ for a more accurate value, differing from the former about $\frac{1}{10}$ of an inch. It is needless to carry the approximation farther. Thus we see that a weir which dams up the whole of the former current of three feet deep, will only raise the waters of this river one foot.

The same rule serves for showing how high we ought to raise this weir in order to produce any given rise of the waters, whether for the purposes of navigation, or for taking off a draft to drive mills, or for any other service; for if the breadth of the river remain the same, the water will still flow over the weir with nearly the same depth. A very small and hardly perceptible difference will indeed arise from the diminution of slope occasioned by this rise, and a consequent diminution of the velocity with which the river approaches the weir. But this difference must always be a small fraction of the second term of our answer; which

term is itself very small; and even this will be compensated, in some degree, by the freer fall which the water will have over the weir. Practical Inferences.

If the intended weir is not to have the whole breadth of the river (which is seldom necessary even for the purposes of navigation), the waters will be raised higher by the same height of the wasteboard. The calculation is precisely the same for this case. Only in the second term, which gives the head of water corresponding to the velocity of the river, l must still be taken for the whole breadth of the river, while in the first term l is the length of the wasteboard. Also $\sqrt{2g}$ must be a little less, on account of the contractions at the ends of the weir, unless these be avoided by giving the masonry at the ends of the wasteboard a curved shape on the upper side of the wasteboard. This should not be done when the sole object of the weir is to raise the surface of the waters. Its effect is but trifling at any rate, when the length of the wasteboard is considerable, in proportion to the thickness of the sheet of water flowing over it.

The following comparisons of this rule with experiment will give our readers some notion of its utility.¹

Discharge of the Weir per second.	Head producing the velocity at the Weir.	Head producing the velocity above it.	Calculated Height of the River above the Wasteboard.	Observed Height.
Inches.	Inches.	Inches.	Inches.	Inches.
3888	7.302	0.625	6.677	6.583
2462	5.385	0.350	5.035	4.750
1112	3.171	0.116	3.055	3.166
259	1.201	0.0114	1.189	1.250

It was found extremely difficult to measure the exact height of the water in the upper stream above the wasteboard. The curvature AI extended several feet up the stream. Indeed there must be something arbitrary in this measurement, because the surface of the stream is not horizontal. The deviation should be taken, not from a horizontal plane, but from the inclined surface of the river.

It is plain that a river cannot be fitted for continued navigation by weirs. These occasion interruptions; but a few inches may sometimes be added to the waters of a river by a bar, which may still allow a flat-bottomed lighter or a raft to pass over it. This is a very frequent practice in Holland and Flanders; and a very cheap and certain conveyance of goods is there obtained by means of streams which we would think no better than boundary ditches, and unfit for every purpose of this kind. By means of a bar the water is kept up a very few inches, and the stream has free course to the sea. The shoot over the bar is prevented by means of another bar placed a little way below it, lying flat in the bottom of the ditch, but which may be raised up on hinges. The lighterman makes his boat fast to a stake immediately above the bar, raises the lower bar, brings over his boat, again makes it fast, and, having laid down the other bar again, proceeds on his journey. This contrivance answers the end of a lock at a very trifling expense; and though it does not admit of what we are accustomed to call navigation, it gives a very sure conveyance, which would otherwise be impossible. When the waters can be raised by bars, so that they may be drawn off for machinery or other purposes, they are preferable to weirs, because they do not obstruct floating with rafts, and are not destroyed by the ice.

PROB. III. Given the height of a bar, the depth of water

¹ This table from Du Buat is expressed in French measures.

Practical
Inferences

both above and below it, and the width of the river, to determine the discharge.

This is by no means so easily solved as the discharge over a weir, and we cannot do it with the same degree of evidence. We imagine, however, that the following observations will not be very far from a true account of the matter.

We may first suppose a reservoir LFBM (fig. 22) of stagnant water, and that has a wasteboard of the height AB. We may then determine, by the foregoing problems, the discharge through the plane EC. With respect to the discharge through the part CA, it should be equal to the product of this part of the section by the velocity corresponding to the fall EC, which is the difference of the heights of water above and below the bar; for, because the difference of Ea and Ca is equal to EC, every particle a of water in the plane CA is pressed in the direction of this stream with the same force, viz. the weight of the column EC. The sum of these discharges should be the whole discharge over the bar; but since the bar is set up across a running river, its discharge must be the same with that of the river. The water of the river, when it comes to the place of the bar, has acquired some velocity by its slope or other causes, and this corresponds to some height FE. This velocity, multiplied by the section of the river, having the height EB, should give a discharge equal to the discharge over the bar.

To avoid this complication of conditions, we may first compute the discharge of the bar in the manner now pointed out, without the consideration of the previous velocity of the stream. This discharge will be a little too small. If we divide it by the section FB, it will give a primary velocity too small, but not far from the truth. Therefore we shall get the height FE, by means of which we shall be able to determine a velocity intermediate between DG and CH, which would correspond to a weir, as also the velocity CH, which corresponds to the part of the section CA, which is wholly under water. Then we correct all these quantities by repeating the operation with them instead of our first assumptions.

Du Buat found this computation extremely near the truth, but in all cases a little greater than observation exhibited.

We may now solve the problem in the most general terms.

PROB. IV. Given the breadth, depth, and the slope of a river, if we confine its passage by a bar or weir of a known height and width, to determine the rise of the waters above the bar.

The slope and dimensions of the channel being given, our formula will give us the velocity and the quantity of water discharged. Then, by Problem II., find the height of water above the wasteboard. From the sum of these two heights deduct the ordinary depth of the river. The remainder is the rise of the waters. For example:

Let there be a river whose ordinary depth is 3 feet, and breadth 40, and whose slope is $1\frac{1}{2}$ inch in 100 fathoms, or $\frac{1}{4800}$. Suppose a weir on this river 6 feet high and 18 feet wide.

We must first find the velocity and discharge of the river in its natural state; we have $l = 480$ inches, $h = 36$, $\frac{1}{s} = \frac{1}{4800}$. Our formula of uniform motion gives $V = 23.45$, and $D = 405216$ cubic inches.

The contraction obtains here on the three sides of the orifice. We may therefore take $\sqrt{2}G = 26.1$. (This ex-

ample is Du Buat's, and all the measures are French.) We have also a (the height of the weir) $= 72$, and $2g = 724$.

Practical
Inferences.

Then the equation $h = \left(\frac{D}{0.431 l \sqrt{2G}} \right)^{\frac{2}{3}} - \left(\frac{D}{l \sqrt{2g(a+h)}} \right)^2$

becomes $h = 30.182$. Add this to the height of the weir, and the depth of the river above the sluice is 102.182 inches $= 8$ feet and 6.182 inches. From this take 3 feet, and there remains 5 feet and 6.182 inches for the rise of the waters.

There is, however, an important circumstance in this rise of the waters, which must be distinctly understood before we can say what are the interesting effects of this weir. This swell extends, as we all know, to a considerable distance up the stream, but is less sensible as we go away from the weir. What is the distance to which the swell extends, and what increase does it produce in the depth at different distances from the weir?

If we suppose that the slope and the breadth of the channel remain as before, it is plain, that as we come down the stream from that point where the swell is insensible, the depth of the channel increases all the way to the dam. Therefore, as the same quantity of water passes through every section of the river, the velocity must diminish very nearly in the same proportion that the section increases. But this being an open stream, and therefore the velocity being inseparably connected with the slope of the surface, it follows, that the slope of the surface must diminish all the way from that point where the swell of the water is insensible to the dam. The surface, therefore, cannot be a simple inclined plane, but must be concave upwards, as represented in fig. 23,

Fig. 23.

where FKL represents the channel of a river, and FB the surface of the water running in it. If this be kept up to A by a weir AL, the surface will be a curve FIA, touching the natural surface F at the beginning of the swell, and the line AD which touches it in A will have the slope S corresponding to the velocity which the waters have immediately before going to the weir. We know this slope, because we are supposed to know the discharge of the river and its slope and other circumstances before barring it with a dam; and we know the height of the dam IL, and therefore the new velocity at A, or immediately above A, and consequently the slope S. Therefore, drawing the horizontal lines DC, AG, it is plain that CB will be the primary slope of the river, and CA, the slope S corresponding to the velocity in the immediate neighbourhood of A, because these verticals have the same horizontal distance DC. We have therefore $CB : CA = S : s$ very nearly, and $S - s : s = CB - CA : CA = AB : CA$. There-

fore $CA = \frac{AB \times s}{S - s} = \frac{ILs}{S - s}$. But $DA = CA \times S$, by our definition of slope; therefore $DA = \frac{ILSs}{S - s}$.

This is all that we can say with precision of this curve. Du Buat examined what would result from supposing it an arc of a circle. In this case we should have $DA = DF$, and AF very nearly equal to $2AD$; and as we can thus find AD, we get the whole length FIA of the swell, and also the distances of any part of the curve from the primitive surface FB of the river; for these will be very nearly in the duplicate proportion of their distances from F. Thus ID will be one fourth of AB, &c. Therefore we should obtain the depth Id of the stream in that place. Getting the depth of the stream, and knowing the discharge, we get the velocity, and can compare this with the slope of the surface at I. This should be the slope of that

Practical
Inferences.

part of the arc of the circle. Making this comparison, he found these circumstances to be incompatible. He found that the section and swell at I, corresponding to an arc of a circle, gave a discharge nearly one fourth too great (they were as 405216 to 492142). Therefore the curve is such that AD is greater than DF, and that it is more incurvated at F than at A. He found, that making DA to DF as 10 to 9, and the curve FIA an arc of an ellipse whose longer axis was vertical, would give a very nice correspondence of the sections, velocities, and slopes. The whole extent of the swell, therefore, can never be double of AD, and must always greatly surpass AD; and these limits will do very well for every practical question. Therefore, making DF nine tenths of AD, and drawing the chord AD, and making DI one half of D i, we shall be very near the truth. Then we get the swell with sufficient precision for any point H between F and D, by making $FD^2 : FH^2 = ID : Hh$; and if H is between D and A, we get its distance from the tangent DA by a similar process.

It only remains to determine the swell produced in the waters of a river by the erection of a bridge or cleaning sluice, which contracts the passage. This requires the solution of

PROB. V. Given the depth, breadth, and slope of a river, to determine the swell occasioned by the piers of a bridge or sides of a cleaning sluice, which contract the passage by a given quantity, for a given length of channel.

This swell depends on two circumstances.

1. The whole river must pass through a narrow space, with a velocity proportionably increased; and this requires a certain head of water above the bridge.

2. The water, in passing the length of the piers with a velocity greater than that corresponding to the primary slope of the river, will require a greater slope in order to acquire this velocity.

Let V be the velocity of the river before the erection of the bridge, and K the quotient of the width of the river divided by the sum of the widths between the piers. If the length of the piers, or their dimension in the direction of the stream, is not very great, KV will nearly express the velocity of the river under the arches; and if we suppose for a moment the contraction (in the sense hitherto used) to be nothing, the height producing this velocity will be $\frac{K^2 V^2}{2g}$. But the river will not rise so high, having already

a slope and velocity before getting under the arches, and the height corresponding to this velocity is $\frac{V^2}{2g}$; therefore

the height for producing the augmentation of velocity is $\frac{K^2 V^2}{2g} - \frac{V^2}{2g}$. But if we make allowance for contraction, we must employ a co-efficient 2G less than 2g, and we must multiply the height now found by $\frac{2g}{2G}$. It will then become

$\left(\frac{K^2 V^2}{2g} - \frac{V^2}{2g}\right) \frac{2g}{2G} = \frac{V^2}{2G} (K^2 - 1)$. This is that part of the swell which must produce the augmentation of velocity.

With respect to what is necessary for producing the additional slope between the piers, let p be the natural slope of the river (or rather the difference of level in the length of the piers) before the erection of the bridge, and corresponding to the velocity V; $K^2 p$ will very nearly express the difference of superficial level for the length of the piers, which is necessary for maintaining the velocity KV through the same length. The increase of slope therefore is $K^2 p - p = p(K^2 - 1)$. Therefore the whole swell will be $\left(\frac{V^2}{2G} + p\right) (K^2 - 1)$.

Practical
Inferences.

These are the chief questions or problems on this subject which occur in the practice of an engineer; and the solutions which we have given may in every case be depended on as very near the truth, and we are confident that the errors will never amount to one fifth of the whole quantity. We are equally certain, that of those who call themselves engineers, and who, without hesitation, undertake jobs of enormous expense, not one in ten is able even to guess at the result of such operations, unless the circumstances of the case happen to coincide with those of some other project which he has executed, or has distinctly examined; and very few have the sagacity and penetration necessary for appreciating the effects of the distinguishing circumstances which yet remain. The society established for the encouragement of arts and manufactures could scarcely do a more important service to the public in the line of their institution, than by publishing in their transactions a description of every work of this kind executed in the kingdom, with an account of its performance. This would be a most valuable collection of experiments and facts. The unlearned practitioner would find among them something which resembles in its chief circumstances almost any project which could occur to him in his business, and would tell him what to expect in the case under his management; and the intelligent engineer, assisted by mathematical knowledge, and the habit of classing things together, would frequently be able to frame general rules. To a gentleman qualified as was the Chevalier du Buat, such a collection would be inestimable, and might suggest a theory as far excelling his as he has excelled all other writers.

We shall conclude this article with some observations on the methods which may be taken for rendering small rivers and brooks fit for inland navigation, or at least for floatage. We get much instruction on this subject from what has been said concerning the swell produced in a river by weirs, bars, or any diminution of its former section. Our knowledge of the form which the surface of this swell affects will furnish rules for spacing these obstructions in such a manner, and at such distances from each other, that the swell produced by one shall extend to the one above it.

If we know the slope, the breadth, and the depth of a river, in the droughts of summer, and have determined on the height of the floodgates, or keeps, which are to be set up in its bed, it is evident that their stations are not matters of arbitrary choice, if we would derive the greatest possible advantage from them.

Some rivers in Flanders and Italy are made navigable in some sort by simple sluices, which, being shut, form magazines of water, which, being discharged by opening the gates, raises the inferior reach enough to permit the passage of the craft which are kept on it. After this momentary rise the keeps are shut again, the water sinks in the lower reach, and the lighters which were floated through the shallows are now obliged to draw into those parts of the reach where they can lie afloat till the next supply of water from above enables them to proceed. This is a very rude and imperfect method, and unjustifiable at this day, when we know the effect of locks, or at least of double gates. We do not mean to enter on the consideration of these contrivances, and to give the methods of their construction, in this place, but refer our readers to what has been already said on this subject in the article NAVIGATION INLAND, and to what will be said in the article WATER-WORKS. At present we confine ourselves to the single point of husbanding the different falls in the bed of the river, in such a manner that there may be everywhere a sufficient depth of water; and, in what we have to deliver on the subject, we shall take the form of an example to illustrate the application of the foregoing rules.

Suppose then a river forty feet wide and three feet deep

Practical Inferences. in the droughts of summer, with a slope of one in 4800. This, by the formula of uniform motion, will have a velocity = $23\frac{1}{2}$ inches per second, and its discharge will be 405216 cubic inches, or $234\frac{1}{2}$ feet. It is proposed to give this river a depth of not less than five feet in any place, by means of floodgates of six feet in height and eighteen feet in width.

We first compute the height at which this body of $234\frac{1}{2}$ cubic feet of water will discharge itself over the floodgates. This we shall find by Prob. II. to be $30\frac{1}{4}$ inches, to which adding 72, the height of the gate, we have $102\frac{1}{4}$ for the whole height of the water above the floor of the gate; the primitive depth of the river being 3 feet, the rise or swell 5 feet $6\frac{1}{4}$ inches. In the next place, we find the range or sensible extent of this swell by Prob. I. and the observations which accompany it. This will be found to be nearly 9177 fathoms. Now, since the primitive depth of the river is three feet, there is only wanted two feet of addition; and the question is reduced to the finding what point of the curved surface of the swell is two feet above the tangent plane at the head of the swell, or how far this point is from the gate. The whole extent being 9177 fathoms, and the deviations from the tangent plane being nearly in the duplicate ratio of the distances from the point of contact, we may institute this proportion, $66\frac{1}{4} : 24 = 9177^2 : 5526^2$. The last term is the distance (from the head of the swell) of that part of the surface which is two feet above the primitive surface of the river. Therefore $9177 - 5526$, or 3651 fathoms, is the distance of this part from the floodgate; and this is the distance at which the gates should be placed from each other. No inconvenience would arise from having them nearer, if the banks be high enough to contain the waters; but if they are farther distant, the required depth of water cannot be had without increasing the height of the gates; but if reasons of convenience should induce us to place them nearer, the same depth may be secured by lower gates, and no additional height will be required for the banks. This is generally a matter of moment, because the raising of water brings along with it the chance of flooding the adjoining fields. Knowing the place where the swell ceases to be sensible, we can keep the top of the intermediate floodgate at the precise height of the curved surface of the swell by means of the proportionality of the deviations from the tangent to the distances from the point of contact.

But this rule will not do for a gate which is at a greater distance from the one above it than the 3651 fathoms already mentioned. We know that a higher gate is required, producing a more extensive swell; and the one swell does not coincide with the other, although they may both begin from the same point A. Nor will the curves even be similar, unless the thickness of the sheet of water flowing over the gate be increased in the same ratio. But this is not the case, because the produce of the river, and therefore the thickness of the sheet of water, is constant. But we may suppose them similar without erring more than two or three decimals of an inch; and then we shall have $AF : AL = fF : DL$; from which, if we take the thickness of the sheet of water already calculated for the other gates, there will remain the height of the gate DI..

By following these methods, instead of proceeding by random guesses, we shall procure the greatest depth of water at the smallest expense possible.

Effects of freshes, But there is a circumstance which must be attended to, and which, if neglected, may in a short time render all our works useless. These gates must frequently be open in the time of freshes; and as this channel then has its natural slope increased in every reach by the great contraction of

the section in the gates, and also rolls along a greater body of water, the action of the stream on its bed must be increased by the augmentation of velocity which these circumstances will produce; and although we may say that the general slope is necessarily secured by the cills of the floodgates, which are paved with stone or covered with planks, yet this will not hinder this increased current from digging up the bottom in the intervals, undermining the banks, and lodging the mud and earth thus carried off in places where the current meets with any check. All these consequences will assuredly follow if the increased velocity is greater than what corresponds to the regimen relative to the soil in which the river holds on its course.

In order therefore to procure durability to works of this and of like kind, which are generally of enormous expense, the local circumstances must be most scrupulously studied. It is not the ordinary hurried survey of an engineer that will free us from the risk of our navigation becoming very troublesome by the rise of the waters being diminished from their former quantity, and banks formed at a small distance below every sluice. We must attentively study the nature of the soil, and discover experimentally the velocity which is not inconsistent with the permanency of the channel. If this be not a great deal less than that of the river when accelerated by freshes, the regimen may be preserved after the establishment of the gate, and no great changes in the channel will be necessary; but if, on the other hand, the natural velocity of the river during its freshes greatly exceeds what is consistent with stability, we must enlarge the width of the channel, that we may diminish the hydraulic mean depth, and along with this the velocity. Therefore, knowing the quantity discharged during the freshes, divide it by the velocity of regimen, or rather by a velocity somewhat greater (for a reason which will appear by and by), the quotient will be the area of a new section. Then taking the natural slope of the river for the slope which it will preserve in this enlarged channel, and after the cills of the floodgates have been fixed, we must calculate the hydraulic mean depth, and then the other dimensions of the channel. And, lastly, from the known dimensions of the channel and the discharge (which we must now compute), we proceed to calculate the height and the distances of the floodgates, adjusted to their widths, which must be regulated by the room which may be thought proper for the free passage of the lighters which are to ply on the river. An example will illustrate the whole of this process.

Suppose then a small river having a slope of two inches in 100 fathoms, or $\frac{1}{5000}$, which is a very usual declivity of such small streams, and whose depth in summer is two feet, but subject to floods which raise it to nine feet. Let its breadth at the bottom be eighteen feet, and the base of its slanting sides four thirds of their height. All of these dimensions are very conformable to the ordinary course of things. It is proposed to make this river navigable in all seasons by means of keeps and gates placed at proper distances; and we want to know the dimensions of a channel which will be permanent in a soil which begins to yield to a velocity of eighty inches per second, but will be safe under a velocity of twenty-four.

The primitive channel having the properties of a rectangular channel, its breadth during the freshes must be $B = 30$ feet, or 360 inches, and its depth h nine feet or 108 inches; therefore its hydraulic mean depth $d = \frac{Bh}{B + 2h} = 61.88$ inches. Its real velocity, therefore, during the freshes, will be 38.9447 inches, and its discharge 1514169 cubic inches or $876\frac{1}{2}$ cubic feet per second. We see therefore that the natural channel will not be permanent, and will be very quickly destroyed or changed by this great velocity. We have two methods for procuring stability, viz.

Practical Inferences. diminishing the slope, or widening the bed. The first method will require the course to be lengthened in the proportion of 24^3 to 38.94^3 , or nearly of 38 to 100. The expense of this would be enormous. The second method will require the hydraulic mean depth to be increased nearly in the same proportion (because the velocities are nearly as $\frac{\sqrt{d}}{\sqrt{s}}$). This will evidently be much less costly and, even to procure convenient room for the navigation, must be preferred.

We must now observe, that the great velocity of which we are afraid obtains only during the winter floods. If therefore we reduce this to 24 inches, it must happen that the autumnal freshes, loaded with sand and mud, will certainly deposit a part of it, and choke up our channel below the floodgates. We must therefore select a mean velocity somewhat exceeding the regimen, that it may carry off these depositions. We shall take 27 inches, which will produce this effect on the loose mud without endangering our channel in any remarkable degree.

Therefore we have, by the theorem for uniform motion,

$$V = 27 = \frac{297(\sqrt{d} - 0.1)}{\sqrt{s} - 1, \sqrt{s} + 1.6} - 0.3(\sqrt{d} - 0.1).$$
 Calculating the divisor of this formula, we find it = 55.884. Hence

$$\sqrt{d} - 0.1 = \frac{27}{\frac{297}{55.884} - 0.3} = 5.3483, \text{ and therefore } d$$

= $30\frac{1}{2}$. Having thus determined the hydraulic mean depth, we find the area S of the section by dividing the discharge 1514169 by the velocity 27. This gives us 56080.368. Then we get the breadth B by the formula formerly given $B = \sqrt{\left(\frac{S}{2d}\right)^2 - 2S} + \frac{S}{2d} = 1802.296$ inches, or 150.19 feet, and the depth $h = 31.115$ inches.

With these dimensions of the section, we are certain that the channel will be permanent; and the cills of the floodgate being all fixed agreeably to the primitive slope, we need not fear that it will be changed in the intervals by the action of the current. The gates being all open during the freshes, the bottom will be cleared of the whole deposited mud.

Station of the floodgates, &c.

We must now station the floodgates along the new channel, at such distances that we may have the depth of water which is proper for the lighters that are to be employed in the navigation. Suppose this to be four feet. We must first of all learn how high the water will be kept in this new channel during the summer droughts. There remained in the primitive channel only two feet, and the section in this case had twenty feet eight inches mean width; and the discharge corresponding to this section and slope $\frac{1}{800}$ is, by the theorem of uniform motion, 130849 cubic inches per second. To find the depth of water in the new channel corresponding to this discharge and the same slope, we must take the method of approximation formerly exemplified, remembering that the discharge D is 130849, and the breadth B is 1760.8 at the bottom (the slant sides being four thirds). These data will produce a depth of water = $6\frac{1}{2}$ inches. To obtain four feet therefore behind any of the floodgates, we must have a swell of $41\frac{1}{2}$ inches produced by the gate below.

We must now determine the width of passage which must be given at the gates. This will regulate the thickness of the sheet of water which flows over them when shut; and this, with the height of the gate, fixes the swell at the gate. The extent of this swell, and the elevation of every point of its curved surface above the new surface of the river, require a combination of the height of swell at the floodgate, with the primitive slope and the new velocity.

Practical Inferences. These being computed, the stations of the gates may be assigned, which will secure four feet of water behind each in summer. We need not give these computations, having already exemplified them all with relation to another river.

This example not only illustrates the method of proceeding, so as to be insured of success, but also gives us a precise instance of what must be done in a case which cannot but frequently occur. We see what a prodigious excavation is necessary in order to obtain permanency. We have been obliged to enlarge the primitive bed to about thrice its former size, so that the excavation is at least two thirds of what the other method required. The expense, however, will still be vastly inferior to the other, both from the nature of the work and the quantity of ground occupied. At all events, the expense is enormous, and what could never be repaid by the navigation, except in a very rich and populous country.

There is another circumstance to be attended to. The navigation of this river by sluices must be very desultory, unless they are extremely numerous, and of small heights. The natural surface of the swell being concave upwards, the additions made by its different parts to the primitive height of the river decrease rapidly as they approach to the place A (fig. 23), where the swell terminates; and three gates, each of which raises the water one foot when placed at the proper distance from each other, will raise the water much more than two gates at twice this distance, each raising the water two feet. Moreover, when the elevation produced by a floodgate is considerable, exceeding a very few inches, the fall and current produced by the opening of the gate is such that no boat can possibly pass up the river, and it runs imminent risk of being overset and sunk in the attempt to go down the stream. This renders the navigation desultory. A number of lighters collect themselves at the gates, and wait their opening. They pass through as soon as the current becomes moderate. This would not, perhaps, be very hurtful in a regulated navigation, if they could then proceed on their voyage. But the boats bound up the river must stay on the upper side of the gate which they have just now passed, because the channel is now too shallow for them to proceed. Those bound down the river can only go to the next gate, unless it has been opened at a time nicely adjusted to the opening of the one above it. The passage downwards *may*, in many cases, be continued, by very intelligent and attentive lockmen; but the passage up *must* be exceedingly tedious. Nay, we may say, that *while* the passage downwards is continuous, it is but in a very few cases that the passage upward is practicable. If we add to these inconveniences the great danger of passes during the freshes, while all the gates are open, and the immense and unavoidable accumulations of ice, on occasion even of slight frosts, we may see that this method of procuring an inland navigation is amazingly expensive, desultory, tedious, and hazardous. It did not therefore merit, on its own account, the attention we have bestowed on it. But the discussion was absolutely necessary, in order to show what must be done in order to obtain effect and permanency, and thus to prevent us from engaging in a project which, to a person not duly and confidently informed, is so feasible and promising. Many professional engineers are ready, and with honest intentions, to undertake such tasks; and by avoiding this immense expense, and contenting themselves with a much narrower channel, they succeed: witness the old navigation of the river Mersey. But the work has no duration; and, not having been found very serviceable, its cessation is not matter of much regret. The work is not much spoken of during its continuance. It is soon forgotten, as well as its failure, and engineers are found ready to engage for such another.

It was not a very refined thought to change this imper-

Introduc-
tion of
locks.

fect mode for another free from most of its inconveniences. A boat was brought up the river, through one of these gates, only by raising the waters of the inferior reach, and depressing those of the upper: and it could not escape observation, that when the gates were far asunder, a vast body of water must be discharged before this could be done, and that it would be a great improvement to double each gate, with a very small distance between. Thus a very small quantity of water would fill the interval to the desired height, and allow the boat to come through; and this thought was the more obvious, from a similar practice having preceded it, viz. that of navigating a small river by means of double bars, the lowest of which lay flat in the bottom of the river, but could be raised up on hinges. We have mentioned this already; and it appears to have been an old practice, being mentioned by Stevinus in his valuable work on sluices, published about the beginning of the seventeenth century; yet no trace of this method is to be found of much older dates. It occurred, however, accidentally, pretty often in the flat countries of Holland and Flanders, which being the seat of frequent wars, almost every town and village was fortified with wet ditches, connected with the adjoining rivers. Stevinus mentions particularly the works of Condé, as having been long employed, with great ingenuity, for rendering navigable a very long stretch of the Scheldt. The boats were received into the lower part of the fosse, which was separated from the rest by a stone batardeau, serving to keep up the waters in the rest of the fosse about eight feet. In this were a sluice and another dam, by which the boats could be taken into the upper fosse, which communicated with a remote part of the Scheldt, by a long canal. This appears to be one of the earliest locks.

In the first attempt to introduce this improvement in the navigation of rivers already kept up by weirs, which gave a partial and interrupted navigation, it was usual to avoid the great expense of the second dam and gate, by making the lock altogether detached from the river, within land, and having its basin parallel to the river, and communicating by one end with the river above the weir, and by the other end with the river below the weir, and having a floodgate at each end. This was a most ingenious thought; and it was a prodigious improvement, free from all the inconveniences of currents, ice, &c. &c. It was called a *schluseel*, or lock, with considerable propriety; and this was the origin of the word *sluice*, and of our application of its translation *lock*. This practice being once introduced, it was not long before engineers found that a complete separation of the navigation from the bed of the river was not only the most perfect method for obtaining a sure, easy, and uninterrupted navigation, but that it was in general the most economical in its first construction, and subject to no risk of deterioration by the action of the current, which was here entirely removed. Locked canals, therefore, have almost entirely supplanted all attempts to improve the natural beds of rivers; and this is hardly ever attempted except in the flat countries, where they can hardly be said to differ from horizontal canals.

Conclud-
ing obser-
vations.

The attentive reader must have observed our anxiety to render this dissertation worthy of his notice, by making it practically useful. We have on every occasion appealed from all theoretical deductions, however specious and well supported, to fact and observation of those spontaneous phenomena of nature which are continually passing in review before us in the motion of running waters. Resting in this manner our whole doctrines on experiment, on the observation of what really happens, and what happens in a way which we cannot or do not fully explain, these spontaneous operations of nature came insensibly to acquire a particular value in our imagination. It has also happened in the course of our reflections on these subjects, that these

phenomena have frequently presented themselves to our view in groups, not less remarkable for the extent and the importance of their consequences, than for the simplicity, and frequently the seeming insignificance, nay frivolity, of the means employed. Our fancy has therefore been sometimes warmed with the view of a something, an

Practical
Inferences.

Ens agitans molem, et magno se corpore miscens.

This has sometimes made us express ourselves in a way that is susceptible of misinterpretation, and may even lead into a mistake of our meaning.

We therefore find ourselves obliged to declare, that by the term *NATURE*, which we have so frequently used *con amore*, we do not mean that indescribable idol which the self-conceit and vanity of some philosophers or pretended philosophers have set up and ostentatiously worshipped, that *ens rationis*, that creature of the imagination, which has long been the object of cool contemplation in the closet of the philosopher, and has shared his attention with many other playthings of his ever-working fancy. By *Nature* we mean that admirable system of general laws, by which the adored Author and Governor of the universe has thought fit to connect the various parts of this wonderful and goodly frame of things, and to regulate all their operations.

We are not afraid of continually appealing to the laws of nature; and, as we have already observed in the article *PHILOSOPHY*, we consider these general laws as the most magnificent displays of Infinite Wisdom, and the contemplation of them as the most cheering employment of our understandings.

Ignescit illis vigor et celestis origo
Semnibus.

At the same time we despise the cold-hearted philosopher who stops short here, and is satisfied, perhaps inwardly pleased, that he has completely accounted for every thing by the laws of unchanging nature; and we suspect that this philosopher would analyse with the same frigid ingenuity, and explain by irresistible *σρογν*, the tender attachment of her whose breast he sucked, and who by many anxious and sleepless nights preserved alive the pining infant. But let us rather listen to the words of him who was the most sagacious observer and the most faithful interpreter of nature's laws, our illustrious countryman Sir Isaac Newton.

“Elegantissima hæc rerum compages non nisi consilio et *dominio* entis sapientissimi et potentissimi oriri potuit. Omnia, simili constructa consilio, suberunt *unius* dominio. Ille omnia regit, non ut *anima mundi*, sed ut universorum dominus. Propter dominium suum, dominus deus *παρα-κράτης* nuncupatur. Deus ad servientes respicit, et *dilectus* est dominatio dei, non in corpus proprium, uti sentiunt quibus deus est natura seu anima mundi, sed in servos. Deus summus est ens eternum, infinitum, absolute perfectum. Ens utique perfectum, at sine dominio, non est dominus deus. Hunc cognoscimus, solummodo per proprietates ejus et attributa. Attribuntur ut ex phenomenis dignoscuntur. Phenomena sunt sapientissimæ et optimæ rerum structuræ, atque cause finales. Hunc admiramur ob perfectiones; hunc veneramur et colimus ob dominum.”

Our readers will probably be pleased with the following list of authors who have treated professedly of the motions of rivers: Guglielmini *De Fluvio et Castellis Aquarum*—Dambius *Illustratus*; Grandi *De Castellis*; Zondrini *De Motu Aquarum*; Frisius *De Fluvio*; Jacobi *Idrostatici Idraulici*; Michelotti, Sparaco *Idraulici*; Benba *Architecture Hydraulique*; Bossut, *Hydrodynamique*; Du Buat, *Hydraulique*; Silberschlag, *Théorie des Eaux*; Laites *de M. l'Épinasse au P. Road-
Making.

RIVOLI, a town of the Sardinian kingdom, in the division and 10 miles W. of Turin, with which it is connected by a broad, straight avenue of elms. It stands in a beautiful position, in a rich plain, intersected by canals, at the foot of the lowest slopes of the Alps. On a height above the town rises a large but unfinished royal palace; and there are churches, schools, an hospital, and a court of justice. Many villas stud the country round about, as the climate is very healthy. Woollen fabrics, linen, and macaroni are made here. Pop. 5195. This town is not to be confounded with another of the same name in Austrian Italy, 14 miles N.W. of Verona. It was at the latter place the French under Massena defeated the Austrians in 1797.

RIZI, FRANCISCO, a talented Spanish painter, was born at Madrid in 1608, and studied under Vicencio Carducho. He was one of those whose very precocity proved a misfortune. His easy dexterity of hand led him to despise all care and elaboration. The most difficult subjects were dashed off without any great regard to truth or accuracy. His appointment to the office of painter to the king, and the many commissions that in consequence pressed in upon him, only confirmed him in his careless habits. He covered whole acres of canvas under the stimulus of no higher motive than that of making money. The result was, that after his death in 1685, his innumerable pictures in the churches of Madrid began to fall into neglect, and at the present day they are scarcely considered worthy of the notice of the art-critic. Rizi's elder brother Juan was also an artist. He was born at Madrid in 1595, became a Benedictine friar as well as a painter, and died at Monte Cassino in 1675.

RJEV, or RSNEV, a town of European Russia, capital of a circle in the government of Twer, on the Volga, 74 miles S.W. of Twer. It has several churches, schools, and benevolent institutions. Horticulture and ship-building are carried on; and there is a considerable trade in fish, hemp, linseed, and other articles. Pop. 13,621.

ROAD, a bay or place of anchorage, at some distance from the shore, whither vessels occasionally repair to receive intelligence, orders, or necessary supplies, or to wait for a fair wind. The excellence of a road consists chiefly in its being protected from the reigning winds and the swell of the sea, in having a good anchoring-ground, and being at a competent distance from the shore. Those which are not sufficiently protected are termed *open roads*.

ROAD-MAKING. There are few departments of practical mechanics in which every individual, at some period or other of his life, is more immediately interested than in the management of roads and pavements. The mechanical theory of the motions of wheel-carriages, and of the nature of the frictions and resistances that they have to overcome, as relating to the ultimate objects for

which roads are constructed, may naturally constitute the first section of an essay on this subject; the second will naturally comprehend the best arrangement of the means for attaining those objects, by the form and construction of such roads and pavements as appear to be the most eligible under various circumstances; and the third may be devoted to some historical illustrations of the principal roads which exist, or which have existed, in various parts of the world.

SECT. I.—Of the Objects of Roads.

The grand object of all modern roads is the accommodation of wheel carriages. The construction of footpaths and of bridle-roads is so simple as to require very little separate consideration; except that, in cities and towns, the convenience of the inhabitants requires that some pains should be taken to avoid dust, and has generally been a reason for employing pavements in preference to gravel roads, which might in some other respects be more eligible.

For facilitating the motion of carriages, the most essential requisite is to have the road as smooth, and as hard, and as level as possible. The wheels of carriages are principally useful in diminishing the friction of the materials; a dray sliding without wheels, even on a railroad of greased and polished iron, would have to overcome a friction as much greater than that of the wheel on its axle as the diameter of the wheel is greater than that of the axle. The wheels assist us also in drawing a carriage over an obstacle; for the path which the axis of the wheel describes is always smoother and less abrupt than the surface of a rough road on which the wheel rolls, and so much the smoother as the wheel is larger, since the portions of larger circles, which constitute the path in question, are less curved than those of smaller ones.

But in all common cases of roads not extremely hard, by far the greater part of the resistance actually exhibited by a road to the motion of a carriage, is that which depends on the continual displacement of a portion of the materials from their inelasticity, which causes them to exert a continual pressure on the fore part of the wheel, without rising behind it to propel it forwards by its re-action, as an elastic substance would do. Hence, in a soft sand, although the axles of the wheels may move in a direction perfectly horizontal, the draught becomes extremely heavy. The more the wheel sinks, the greater is the resistance; and if we suppose the degree of elasticity of the materials, and their immediate resistance at different depths, to be known, we may calculate the whole effect of their action on the wheel, and the force that is required to displace them, in the progressive motion of the carriage. Thus, if the materials were perfectly inelastic, acting only on the preceding half of the immersed portion of the wheel, and their immediate

Road-Making.

pressure or resistance were simply proportional to the depth, like that of fluids, or that of elastic substances compressed, the horizontal resistance would be to the weight nearly as two-fifths of the length of the part immersed at once, in the newly-formed rut, to the diameter of the wheel; or on a still more probable supposition respecting the greater resistance of the more deeply-seated parts of the rut, about half as much as this, or as about one-fifth of the length of the part immersed in the rut to the diameter. Thus, if a coach or waggon, weighing 60 hundredweight, supported by wheels 4 feet in diameter, formed a new rut an inch deep, in a smooth road, the length of the part immersed being about 14 inches, the resistance would, upon the lowest supposition that is at all admissible, be about one-seventeenth of the weight, and more probably about one-ninth or from 6 to 7 hundredweight at least; and if the rut were 2 inches deep, the resistance would be half as much more. But, on any supposition, the increased height, and even the increased breadth, of the wheel, is calculated to diminish the resistance, by diminishing the depth of the part immersed; thus, if a wheel were made four times as high, the length of that part immersed, considering the road as an imperfect fluid, would be doubled, and the resistance would be diminished, theoretically speaking, to about half of its former magnitude; and if the breadth were increased from one to eight, the length of the part immersed would be diminished to about a half, and the resistance would in this case also be reduced to a half.

In soft and boggy soils, as well as in sandy roads, this consideration is of great importance; and the wheels employed for removing heavy weights, in such cases, ought to be as high and as broad as possible consistently with sufficient lightness and economy. But whether a broad, and, at the same time, a low roller, possesses any advantages above a narrow coach-wheel, is a matter much more questionable: it must be remembered that a narrow wheel may often run between stones, where a broader would have to pass over them; and there appears to be no theoretical reason for preferring a low roller, except with respect to a single pair of wheels, as affording a more convenient attachment for the shafts in a moderate inclination, which is both more favourable to the exertion of the horses, and more effective in overcoming the friction; since it has been demonstrated that the angle affording the most advantageous line of draught is exactly the same as the inclination of a plane along which the carriage would just begin to descend by its own weight on the same kind of surface. In fact, however, there is no necessity for fixing the axle-tree precisely in the line of draught; and the principal reason for having the fore wheels lower than the others is for the convenience of turning the carriage more abruptly. A practical road-maker has observed that a good road never suffers from narrow wheels with moderate weights not in rapid motion, but that it is equally worn by the rapid driving of heavy stage-coaches, and by the slow grinding of the conical rollers of overloaded, broad-wheeled waggons.

Such being the operations of the wheels of carriages on sandy or on rough roads, it is easy to perceive how much the hardness and smoothness of the surface must facilitate the draught; it is obvious also that the same qualities must be equally conducive to the durability of the road, since the inequalities will always cause the carriage to fall on it with a certain impetus after being elevated by the irregularities, and the same shock which strains the carriage will also tend to wear away the road still more where it is lowest; and, on the other hand, the resistance of the soft materials before the wheel will tend to tear up the road, as it causes the wheel to thrust them before it.

Details respecting roads have lost much of their interest since the general introduction of railroads; but in places

Road-Making.

where common roads are still much used it will be found now, as formerly, that the interests of the traveller and of the postmaster are somewhat at variance with respect to the qualities of a road. The French postilion keeps to the rough pavement as long as the aching limbs of the ladies in the carriage will allow them to be silent, except when, in going down hill, he saves himself the trouble of locking the wheel by bringing it to the soft edge of the ditch or kennel; and the horses of the Parisian cabriolets, in their excursions to the suburbs, have sagacity enough to incline always to the pavement, when their drivers allow them to have a will of their own; while a single horseman, on the contrary, more commonly finds his steed on the gravel road, if he happen to leave him to his own direction. In Great Britain the roads are commonly managed by commissioners, who have no community of interest with the innkeepers; on the Continent they are under the immediate direction of the different governments, who also appoint the postmasters, while the carriages are almost as uniformly the property of particular individuals, who have no immediate influence on the management of the roads; and this diversity may perhaps explain in some measure the different systems of road-making which prevail on the opposite sides of the Channel. But it may be said of roads as of governments, "that which is best administered is best;" whether a very smooth pavement not too slippery, or a very hard gravel road not worn into great inequalities.

SECT. II.—Of the Mechanical Formation of Roads.

The only strongly-marked division of the different kinds of roads depends on their being paved or gravelled; but each of these classes admits of considerable diversity in the principles on which the road is constructed. The theory of pavement appears to be extremely simple; the stones, however, may be either small or large; the former being understood to be employed without previous preparation of their shape, as in the inferior kind of work which is called "pitching" in the west of England; the latter being more or less cut to fit each other, whether in the form of thick, rough blocks, not very remote from cubes, or of flat and smooth flagstones. In the cities of Great Britain the former are commonly used for horse-pavements, and the latter for foot-passengers; but in Florence the whole breadth of the streets is paved with flagstones placed diagonally, and in Naples the surfaces are nearly as smooth, in both these cases it is necessary to roughen the stones frequently with chisels wherever there is a hill or a bridge, in order to prevent the horses slipping, but in both cities the horses, from habit, are sufficiently sure-footed, even when running with some rapidity. In Milan both kinds of pavements are mixed in the same streets; the smooth in two double lines, for the wheels of carriages coming and going, and the rougher in the intermediate parts, for the feet of the horses, as in the British railroads. But in none of these cities is there much heavy traffic to wear these well-arranged surfaces into such inequalities as would soon be observed in the streets of London if they were so delicately formed; although, until this deterioration actually took place, the locomotion would be luxurious both for the horses and for the passengers, and only ruinous to the coachmakers. The Romans used large and heavy blocks for their roads, cutting them on the spot into such forms as enabled them to be best adjusted to those of the neighbouring stones, though seldom exactly rectangular in their surfaces; and even at Pompeii, where the ruts are worn half through the depth of the blocks, the bottom remains tolerably even, in a longitudinal direction, at least as much so as would be required for carts and other carriages of business.

Our more particular object, however, is, first, the consideration of gravel-roads rather than of pavements; the

Road-Making.

word gravel being here understood to mean in general all stone broken small, whether by nature or by art. The improvement of such roads has long been a subject of great interest with the agricultural and commercial inhabitants of Great Britain. It was soon after the year 1700 that a part of the charge of repairing roads was taken off the respective parishes through which they pass, and levied on the general traveller by means of turnpike-gates; but it was for many years a complaint that the roads were little, if at all, fundamentally improved by the expenditure of the money so raised. This complaint is very energetically advanced in a "Dissertation concerning the present State of the High Roads of England, especially of those near London, wherein is proposed a new Method of Repairing and Maintaining them;" read before the Royal Society in the winter of 1736-37, by Robert Philips, and printed in a small separate volume. The author's great object is to recommend washing the roads by a constant stream, if possible, and at any rate, washing the materials of which they are composed. In this respect, notwithstanding the existence of single roads so situated that the effects of water upon them have been very beneficially introduced, his plans for the universal employment of water have been altogether superseded by later experience; but he remonstrates, with greater propriety, against the practice, which has, however, continued to prevail so generally till of late years, of laying down large heaps of unprepared gravel, to be gradually consolidated into a harder mass, at the expense of the intolerable labour of the poor animals that are obliged to grind it down. As an illustration of the good effect of water, he mentions that even the sediment deposited by it at the bottom of Fleetditch, which was supposed to be a soft mud, and to require removal when the ditch was filled up, proved in fact to be a hard gravelly substance, which afterwards afforded an excellent foundation for the roads and buildings supported by it.

The attention of the public was afterwards directed to the subject of roads and carriages, by several essays which appeared in the *Communications to the Board of Agriculture*, and also in a separate form, under the names of Beaton, Wright, Jessop, Hall, Wilkes, Erskine, Ellis, Cumming, Whetley, Amos, and Booth. We may also refer to Sir Henry Parnell's *Treatise on Roads*; Telford's *Reports*; The Art of *Constructing and Repairing Common Roads*, by Henry Law, and Professor Mahan's *Essay on Road-Making*.

But the suggestions of these writers were in a great measure superseded by the success of Mr Loudon Macadam, a gentleman whose practice was marked by simplicity and economy, though he also had the merit of discovering that the simplest and cheapest methods, in particular cases, especially in that of boggy soils, are also the most effectual. The practical observations which are to be here inserted cannot therefore be so well expressed in any other form as in that of an abstract of Mr Macadam's own directions.

Mr Macadam's leading principles are (*Remarks*, p. 37), "that a road ought to be considered as an artificial flooring, forming a strong, smooth, solid surface, at once capable of carrying great weights, and over which carriages may pass without meeting any impediment."

He proceeds to give directions for repairing an old road and for making a new one, in the form of a communication to a committee appointed by the House of Commons, in the year 1819, with some subsequent corrections.

No additional materials, he observes, are to be brought upon a road, unless in any part of it there be not a quantity of clean stone equal to 10 inches in thickness. The stone already in the road, supposing it to have been made in the usual manner, is to be loosened, and broken so that no piece may exceed SIX OUNCES in weight; the road is

VOL. XIX.

Road-Making.

then to be laid as flat as possible, leaving only a fall of 3 inches from the middle to the sides when the road is 30 feet wide. The stones, thus loosened, are to be dragged to the side by a strong heavy rake, with teeth $2\frac{1}{2}$ inches in length, and there broken; but the stones are never to be broken on the road itself. When the great stones have been removed, and none are left exceeding six ounces in weight, the surface is to be made smooth by a rake, which will also settle the remaining materials into a better consistency, bringing up the stone, and letting the dirt fall down into its place. The road being so prepared, the stone that has been broken by the side is then to be carefully spread over it: this operation requires particular attention, and the future quality of the road will greatly depend on the manner in which it is performed: the stone must not be laid on in shovelful, but scattered over the surface, one shovelful following another, and being spread over a considerable space. Only a small part of the length of the road should be *lifted* in this manner at once; that is, about 2 or 3 yards; five men in a gang should be employed to *lift* it all across, two continually digging up and raking off the large stones, and preparing the road for receiving them again, and the other three breaking them at the side of the road. It may, however, happen that the surveyor may see cause to distribute the labour in a proportion somewhat different. The only proper method of breaking stones, in general, both for effect and for economy, is in a sitting posture. The stones are to be placed in small heaps, and women, boys, and old men past hard labour, may sit down and break them with small hammers into pieces not exceeding *six ounces* in weight.

In some cases it would be unprofitable to lift and relay a road, even if the materials should have been originally too large; for example, the road between Bath and Cirencester was made of large stones, but so friable that in lifting they would have fallen into sand; in this case Mr Macadam merely had the higher parts cut down, and replaced when sifted, and the surface kept smooth, until those materials were gradually worn out; and they were afterwards replaced by stone of a better quality, properly prepared. At Egham it was necessary to remove the whole road, in order to separate the small portion of valuable materials from the mass of soft matter in which they were enveloped, and which was carried away, at a considerable expense, before a good road could be made. But although freestone is by no means calculated to make a durable road, yet by judicious management it may be made to form a good road as long as it lasts. Whenever new stone is to be laid on a road already consolidated, the hardened surface is to be loosened with a pick, in order to enable the fresh materials to unite with the old. A new road, however well it may have been made, will always receive the impressions of the carriage-wheels until it is hardened; a man must therefore attend the road for some time, in order to rake in the tracks made by the wheels; that is, as long as any loose materials are left that can be so employed.

It is always superfluous, and generally injurious, to add to the broken stone any mixture of earth, clay, chalk, or any other matter that will imbibe water and be affected by frost, or to lay anything whatever on the clean stone for the purpose of binding it; *for good stone, well broken, will always combine by its own roughness into a solid substance* with a smooth surface, that will not be affected by the vicissitudes of weather, or disfigured by the action of wheels, which, as they pass over it without a jolt, will consequently be incapable of doing it any considerable injury. The experience of the year 1820 strongly confirmed the inutility and inconvenience of employing chalk with the stone. In January, when a hard frost was succeeded by a sudden thaw, a great number of roads broke up, and the wheels of the carriages penetrated into the original soil;

2 F

Road-Making.

in particular, it was observed that all the roads of which chalk was a component part became nearly impassable; and even roads made over chalky soils gave way in most places. But not one of the roads that had been thoroughly made after these directions was observed to give way.

The tools required for lifting roads are—1. Strong *picks*, but short from the handle to the point; 2. Small *hammers*, weighing about a pound, with a face the size of a shilling, well steeled, and with a short handle; 3. *Rakes* with wooden heads, ten inches in length, and with iron teeth about two and a half inches long, and very strong, for raking out the large stones when the road is broken up, and for keeping it smooth after it has been finished, and while it is consolidating; 4. Very light, broad-mouthed *shovels*, to spread the broken stones and to form the road.

Mr Macadam argues strongly against the old opinion of the necessity of placing a quantity of large stones as a foundation, in order to carry the road over a wet subsoil. He says, that whatever be the nature of the soil, if it be previously "made quite dry," and a covering impenetrable to rain placed over it, the thickness of the covering needs only to depend on its own capability of becoming impervious. Large stones, he says, will constantly work up by the agitation of the traffic on the road, and leave vacuities for the reception of water; and the only way of keeping the stones in their places is to have them of a uniform size. A rocky bottom causes a road to wear out much the faster [acting, probably, as a lower millstone in facilitating the operation of grinding]. "It is a known fact, that a road lasts much longer over a morass than when made over rock. In the neighbourhood of Bridgewater, for example, the materials consumed on a rocky road, when compared with those which are required for a similar road made over the naked surface of the soil, are in the proportion of seven to five." In the summer of 1819, upon some new roads made in Scotland, more than three feet of materials, of various dimensions, were laid down; and more than two-thirds of them, according to our author, were worse than wasted. In such an arrangement the water generally penetrates to the bottom of the trench made to receive the road, and remains there, to do mischief upon every change of weather. To prevent such inconveniences, it is necessary, in wet soils, either to make drains to lower ground, or to raise the road above the general level, instead of making a trench to receive the stones; and from the penetration of rain the solidity of the road itself must protect it. A well-made road, not quite four inches in thickness, was found to have kept the earth below it dry, in the parish of Ashton, near Bristol; but six, eight, or ten inches of materials are generally required to make a firm road, being laid on in successive layers of about two inches in thickness, all well broken, well cleaned, and well sized. Sometimes, indeed, a much greater depth of stone than this is required; in a road, for example, which was made from Lewes to East Bourn entirely upon Mr Macadam's principles, as much as three feet of materials were required in many parts before the road could be sufficiently consolidated; it was, however, ultimately so made, though at an expense of not much less than a thousand pounds a mile.

Mr Macadam maintains that the quantity of stone required for paving is fully sufficient to make an excellent gravel road in any part of the world; and in almost every case materials equally good can be obtained for roads at a still cheaper rate; commonly, indeed, at one-tenth of the expense of pavements. It is, however, in steep ascents that pavements are most objectionable.

The operation of washing gravel Mr Macadam has not found eligible, because it is more expensive than screening or sifting, and less effectual; for about London the common gravel is not capable of being cleaned by any ordinary washing, though the Thames gravel, where it can be pro-

cured, is generally clean and serviceable. Coarse gravel broken, he says, is preferable to fine, as it consolidates more perfectly into a single mass. The old practice of putting a heap of unprepared gravel along the middle of the road, and letting it work its own way gradually to the sides, he thinks every way reprehensible.

The objection to a very convex road is, that travellers only use the middle of it, which is therefore worn into three furrows by the sting of horses and by the wheels; if the road is flatter, it becomes worn more equally. Ditches, he observes, only require to be so deep that the surface of the water in them may be a few inches below the level of the road; the farmer often makes them dangerously deep, on account of the value of the mould that is dug out of them. Mr Macadam would prefer a bog to any other foundation for a road, provided that it would allow a man to walk over it; and he observes, that the resistance to the motion of a carriage would not be materially affected by the foundation, if the road were well made. From Bridgewater to Cross, a part of the road shakes when a carriage passes over it; yet the consumption of materials is stated to be less there than on the limestone rock in the neighbourhood. He does not use any faggots in such cases, nor any stones larger than six ounces in weight; and these never sink in the bog, but unite into one mass like a piece of timber, which rests on it. He makes such a road generally at three different times; and he always prefers working in weather not very dry. The surveyors are directed to carry a pair of scales and a six-ounce weight in their pockets, as a check upon the workmen.

Mr Macadam has generally found reason to approve the usual regulation respecting carriage-wheels; but he thinks broad wheels less advantageous to roads than is commonly supposed. He suggests that the tolls might always be fairly made proportional to the exact number of horses employed; except that the waggoners should be encouraged to harness them in pairs rather than in a line. The conical form of broad wheels he thinks very injurious. Clean flints from the sea-side are among the best materials for roads, and might often be procured cheap by canals; granite chip-pings also, brought as ballast, are excellent; and when the middle of the road has been well made with good stones, the sides may often be left for a few feet less abundantly provided with them, as they are naturally much less exposed to wear.

We have given details of Macadam's plan at considerable length, in order that the reader interested in the subject may form his judgment on a method of constructing roads which was at one time so popular as to threaten to supersede every other. Macadam's great rival in the art of road-making was Telford, whose method was directly opposed to that of Macadam, in requiring that every road should be laid down upon a hard, solid, carefully-prepared foundation; whereas Macadam, as it will have been seen, was indifferent whether the substratum were soft or hard, but of the two he rather preferred the former. Telford was accustomed to regard as the real road, not the surface upon which animals and vehicles moved, but the foundation or sub-road, which, if properly preserved, would last for ever; and in order to preserve it properly, it was covered with suitable materials, renewed from time to time, on which were expended the action of the horses' feet and carriage-wheels, as well as of the weather. This method was adopted with great success on the Holyhead road, the Glasgow and Carlisle road, &c.; and the public had abundant opportunity of testing the merits of the two rival schemes. It is scarcely necessary to say which eventually prevailed. Considerable credit, however, is due to Macadam for improved details and economy in the art of road-making; and we now proceed to describe some of the more important features of Telford's practice. In the first place, the road

Road-Making.

Road-Making.

having been properly levelled, and, where necessary, drained, a regular bottoming of close-set pavement was constructed. The object was to secure the greatest degree of hardness consistent with the materials at hand; and this method is stated to be less expensive than a thick coating of broken stones, while six inches of broken stones is sufficient when laid on pavement. Any kind of common stone may be used for the pavement; and if the stones are laid with their broadest faces downwards, and stone chips be well driven into the interstices, the earthy bed of the road will not be pressed up so as to mix with the coating of broken stones. When this coating is consolidated it will form a solid, uniform mass of stone, and will be very superior in hardness to one of broken stones mixed with the earth of the substratum. On a road of this kind the power required to draw a wagon was 46 lb., while on a road made with a thick coating of broken stone laid on earth it was 65 lb., and with a thick coating of gravel laid on earth it was 147 lb. In places where stone is scarce, but gravel and lime are abundant, concrete may be used for the solid foundation of the road: it should be spread to the depth of 6 inches, and upon this, 6 inches of good hard gravel may be placed in two courses, 3 inches at a time. By using concrete, a good solid road may be formed with round, pebbly gravel, and other materials not well adapted to road-making. The gravel should be free from clay and dirt, and consist of stones and sand, the latter sufficiently abundant to fill up the spaces in the former. Five or six parts of the gravel are to be mixed with ground, unslaked lime, when sufficient water must be added to slack the lime. It is to be well mixed up, and thrown at once into its place and trimmed to the proper form. Just as the concrete is about to set, the first layer of broken stones or screened gravel is to be put on. The broken stones on the surface will quickly wedge together, but round and pebbly gravel stones must be mixed with some binding material, to fill up the interstices and prevent them from rolling about. This binding material is useful in making the road solid; but it makes it spongy in wet weather, and serves to break it up after a thaw. In chalk districts that material may be used for the foundation, but it should be placed at such a depth as to be out of reach of frost. In soft and boggy ground, the foundation should be laid with bushes or bundles of faggots. The best road-metal for the surface should be hard and tough, for which purpose whin-stones, basalts, granite, and beach pebbles are well adapted. Flint is hard but brittle, and is easily crushed; and so also, for a contrary reason, the softer sandstones. The limestones are retentive of water, and are apt to split during a thaw, but the harder and more compact varieties may be used. When gravel is the only road material, it should be screened, and the fine stuff or *hoggin* be reserved for footpaths. The larger stones should be broken, and the screened gravel be spread to the depth of 6 inches. When new roads are opened, men should be employed to keep every rut raked in as soon as it is formed, and guards or fenders should be placed so as to make the carriages pass over every part of the road in turn.

In every road provision must be made for drainage. Surface-drainage is assisted by a gently-convex transverse section. There should be a ditch on each side to carry off all the water that may fall upon the road. Between the footpath and the road, at distances of about 60 feet, drains of tiles or pipes should be formed under the footpath for conveying the water into the ditch. If the surface be properly drained, very little water will find its way to the substratum unless this be a strong clay or wet peat, in which case a system of under-drainage must be adopted, and trenches or drains be formed across the road at distances of 20 or 30 feet.

In improving an old road, it is often desirable to straighten

Road-Making.

its course by cutting off corners and bends, or to improve the level by avoiding or lowering hills, and embanking valleys. It is also desirable to increase the width and make it uniform throughout: the transverse section must be corrected, ruts filled up, and the side ditches cleaned and deepened; trees and hedges too near the road must be cut down, and mud-banks removed. In improving an old road by the common method of heaping on new materials, there is a wasteful expenditure of means; for most old roads usually contain abundant material if properly lifted and applied. Roads should be scraped clean in wet weather, and watered in dry; the fences should be as low as possible, and placed far on the sides of the road, so as not to intercept the sun and wind.

In forming roads through the streets of a busy town, it is even more important than in the country to secure a good foundation. This may be of concrete or of broken stone, or the old road may itself be the foundation, for which purpose the stones must be taken up and laid down again to the proper cross section; and upon this, stone pavement may be laid, some kind of coarse mortar being used. Granite is the best paving-stone, especially that from Guernsey and Aberdeen, as it does not become polished by wear. Next to this the hardest varieties of limestone and freestone may be used. The stones should be in rectangular blocks from 8 to 15 inches in depth, about 18 inches in length, and 3 or 4 inches in width. Narrow stones are found to wear better than wide ones. The courses should break joint, and should abut against a firm kerb on each side of the road. The courses should be commenced on each side and worked towards the centre; the joints between the stones should be thin, and the last stone should fit tightly so as to form a key to the whole. The stones should be well rammed down with a heavy *punner*, and a thin grouting of sand and lime should be poured over the surface, unless the superior plan be adopted of bedding the stones in mortar. Where the road is inclined, the pavement should be laid so as to give horses a hold for their feet; for which purpose the stones may be sloped so as to form a series of ledges or steps, or a course of slate about an inch less in depth than the stones may be inserted between the courses.

Roads have been paved with wooden blocks, but they have in many cases failed for want of a solid foundation, the absence of which caused them to form numerous pits and cavities, and they were also found to be very slippery in wet weather. Some years ago, wooden pavements were in such favour in London, that most of the great thoroughfares were so paved. A large number of patents were taken out for new forms of blocks, and machinery for preparing them, and also for combining and laying them down. Contracts were also entered into for terms of years; so that long after wooden pavements had fallen into disfavour they continued to be used. When these roads were new and in good condition, they were easy to the horses, pleasant to the travellers, and especially so to the inhabitants of crowded thoroughfares, from the cessation of noise. After the wooden roads had been given up, a noiseless wheel was attempted,—that is, a wheel with a band of vulcanized india-rubber let into the tire. Asphaltum roads have also been tried, for which purpose the soft earth is well rammed, and a coarse concrete laid; upon this a finer concrete; and lastly, the asphaltum applied in a liquid state, and before it is quite set covered with sand, slate-dust, plaster of Paris, or powdered chalk, rubbed in with a flat heavy tool of wood; or, for a rough pavement, a clean, sharp grit is used. This kind of road answers tolerably well where the traffic is not considerable, but it is liable to soften under a hot sun, and to exhale a very disagreeable odour.

SECT. III.—Of the Roads of different Ages and Countries.

The ancient Incas of Peru seem to have been the greatest road-makers in the world. The story told by Montaigne (iii. vi., p. 206) of a road in Peru, from Quito to Cuzco, 300 leagues long and 25 paces broad, made of stones 10 feet square, with a running stream and a row of trees on each side, seems to have been literally true. "It was conducted," says Prescott in his *History of Peru*, "over pathless sierras covered with snow; galleries were cut for leagues through the living rock; rivers were crossed by means of bridges that swung suspended in the air; precipices were scaled by stairways hewn out of the native bed; and ravines of hideous depth were filled up with solid masonry." In Italy only, the Romans are said to have made more than 14,000 miles of road, which was generally executed with great care and labour; and many of their roads still remain as the foundation of the most favourite routes of Italian travellers. The more than Roman despot of modern times was as much a Roman in his road-making as in the selfish character of his general policy; and in proportion to the duration of his destiny he performed more than all the Appii and Flamini of antiquity. Whatever his merits may have been, the beneficial effects of his measures remain; and those who have profited by his improvements have no right to criticise his motives with too great severity.

Of the great roads diverging from the gates of ancient Rome, about twelve have been enumerated by antiquaries, and twelve more branched off from these at a small distance from the city; eighteen others commenced in different parts of Italy, and in the whole there are at least fifty, which have been distinguished by appropriate names, without including the military roads through the distant provinces; such, for example, as in England were distinguished by the name of streets, of which many traces yet remain in different parts of the country.

Directly to the sea the Romans travelled by the Ostian Road; along its shores to the north-west by the Aurelian, and to the south-east by the Appian. Next within the Aurelian was the Flaminian, then the Salarian, the Nomentanian, the Tiburtine, the Prænestine, the Lavican, and the Latin; and then the Appian, which was the most ancient of all, having been made as far as Capua, in the 442d year of the city, accompanied to a considerable distance by an aqueduct. The Aurelian road was made in the year 512; the Flaminian about 533.

I. The *Flaminian* Road still affords the great northern approach to Rome by the Porta del Popolo; it led to Foligno, Ancona, and Rimini, and was continued by the *Emilian* to Bologna, and thence to Aquilegia, near Venice; the present mountain route from Bologna to Rome is still facilitated by the remains of the ancient structures. Besides the *Emilian* Road, the Flaminian was also connected with the *Cassian*, leading to Modena; the *Claudian* to Arezzo, Florence, and Lucca: there were also six other branches of less note, each named after its founder.

II. III. The *Salarian* and the *Nomentanian* roads lay to the east of the Flaminian; the former, from the Porto Salara, led through the country of the Sabines by Rieti to Hadria; the latter, from the Porta Sant' Agnese, went north-eastwards to Nomentum.

IV. The *Tiburtine* Road led from the Porta Tiburtina, now San Lorenzo, to Tivoli, with a branch on the right called the Gabian. The large blocks which were employed to form this road, near the town of Tivoli, in ascending from the river, are still in their ancient places; they are accurately fitted together, and present a surface sufficiently smooth, after having been in use for about 2000 years.

V. VI. VII. The three next in order all met at Anagnia, 24 miles beyond Præneste or Palestrina. The *Prænestine*, from the Esquiline gate, now called Porta Maggiore, on account of the magnitude of the ruins of the aqueduct of Clodius, with which it is incorporated, led by Aquinum to Præneste; the *Lavican* led from the same gate, more to the right, by way of Beneventum; and the *Latin* road, from the Porta Latina, went first to Compitum, and from Anagnia proceeded to join the Appian near Capua.

VIII. The *Appian* Road is well known, from the minute description of Horace's progress in his journey to Brundisium, as from the eagerness with which a modern traveller reckons the stages that he has completed on his way to Naples, without a visit from the banditti that infest it. The original extent of this road, from the Colosseum to Capua, was 142 Roman miles; and it was continued 238 miles farther to Brundisium by Julius Cæsar. It was constructed with large stones, or rather rocks, joined together with great care; and it is said to have had a foot-pavement, 2 feet wide on each side, besides the agger, or principal mass of stones in the middle, and the two marginal parts, which were probably unpaved.

IX. The *Ostian* Road led from the Porta di San Paolo, near the Tiber, in a straight line to the mouth of that river.

X. The *Aurelian*, from the Porta Aurelia, a gate which was near the Moles Adriani, or Castle of Sant' Angelo, led by Laurentum to Centumcellæ, or Civita Vecchia to Genoa, and thence by Susa, across the Montenis, as far as Arles in Provence. This seems to have been the oldest passage into the Gauls; it was improved by Pompey the Great under the name of the *Strata Romana*. Several other passages over the Alps are also particularized in the *Itinerary* of Antonine on the roads from Milan to Arles; from Milan to Vienne in Dauphiné, either by the Grecian or by the Cottian Alps, the former north, the latter south of Montenis; from Milan to Strasburg; and from Milan to Mentz.

XI. XII. The *Triumphal* Road began from the Capitol, and went over the Tiber into the country beyond the present site of the Vatican. We may consider as the last of the twelve great roads, originating from Rome, the *Collatine*, leading due north from the Porta Pinciana on the Monte Pincio.

Among the less remarkable roads about the metropolis of the ancient world were also the Campanian, the new and the old Valerian, both leading by Tivoli to the Adriatic; the Tusculan, the Alban, the Ardentine, on the right of the Appian; the Laurentine, a little more to the right, Pliny's villa being mentioned as accessible from either of these last; the Portuensis, from the Porta Portuense, Trasteverina, leading to Ostia; and the Aureli Nova, beginning from the Porta Janiculi, now Porta San Pancrazio, and leading towards Civita Vecchia.

Whether on the foundations of the ancient roads, or in any new lines that have been prepared in modern times by the magnificence of the pontiffs or of the princes, the great roads of Italy are at present almost universally well made and well repaired. In Lombardy, indeed, and throughout the immense plain that extends from the Alps to the Apennines, they are quite as good, in summer at least, as those in England. The cross roads of Italy are, however, greatly neglected; for it is in fact almost exclusively in Great Britain that private and individual exertion supersedes the necessity of public munificence. The intercourse of Italy with the rest of Europe has been greatly facilitated by the improvements made in the two great passages over the Alps by the authority of Bonaparte. The more useful of these improvements are probably those which have been effected on the southern side of Montenis, since they enable the traveller to pass with little danger or difficulty at all seasons of the year; the more magnificent are the works at the Simplon, which, however, are not completely secure from the danger of *avalanches*, whenever fresh snow is lying on the ground. The Apennine portion of the Aurelian road has also been greatly improved by some still more recent operations, so that carriages may now pass with comparative ease and safety from Lucca to Genoa; though, for one stage near Sestri, it is not thought advisable for the travellers to retain their seats within them.

The general declivity of the new road over Montenis is 1 inch in 15 or 20; and it is never greater in the steepest part,—that is, in the fourth and fifth turns that wind up over Lanslebourg,—than 1 in 12. (Derrien, *Notice Historique et Descriptive sur la Route de Montenis*.) The road over the Simplon was executed jointly by the French and Italians, under the government of Bonaparte, from 1801 to 1805. The greatest declivity is 1 inch in 20; so that an English stage coachman might trot his horses up almost the whole way. The longest gallery or tunnel is about 500 feet under ground.

Roanne
||
Robert.

The roads in France are generally rough in their original formation, and still rougher from want of care in repairing them, as the traveller feels to his cost in passing over the primitive mountains in the south of that country, where the roads are certainly very different from those which are made by Macadam across a bog; although some of the more recent French and Flemish pavements, as long as they remain unimpaired, are truly excellent. In Germany they have few pavements; and the roads, except in sandy countries, are generally kept in good repair,—that is, in the south and the west of Germany. Mr Cripps informs us that the great roads in Sweden are beautiful; they are very slightly convex, and made of granite broken to the size of a walnut. The roads of the British Islands are excellent, and in most cases still retain their utility as feeders to railways. (T. Y.) (C. Y.)

ROANNE, a town of France, capital of an arrondissement in the department of Loire, on the left bank of the Loire, here crossed by a stone bridge, 30 miles N. of Montbrison. It is a straggling but well-built place, with broad streets and many handsome houses. The most remarkable buildings are an ancient church, public library, and college buildings. There are also a theatre, hospital, court of law, and chamber of manufactures. Muslin, calico, woollen cloth, leather, porcelain, and other articles, are made here; dyeing and boat-building are also carried on. A considerable transit trade is pursued in the manufactures of Lyons and the south-east of France, as well as in corn, wine, flour, cloth, coal, timber, &c. The Loire is navigable up as far as Roanne, and there is a good quay. By canals and railways this place is connected with the principal towns in the country. Some ancient remains have been discovered in the vicinity. Pop. (1856) 14,952.

ROBERT, King of France, surnamed *Le Sage* ("The Wise"), and *Le Dévot* ("The Devout"), succeeded his father Hugues Capet in A.D. 996, and died in 1031. (See FRANCE)

ROBERT, the name of three kings of Scotland. Robert I., or "The Bruce," was born in 1274, was crowned at Scone in 1306, and died in 1329. (See BRUCE.) Robert II., the first of the Stuart dynasty, and the grandson of the preceding, was born in 1316, succeeded David II. in 1371, and died in 1390. Robert III., whose original name was John, succeeded his father Robert II. in 1390, and died in 1400. (See SCOTLAND.)

ROBERT of Gloucester, a monk who flourished in the latter half of the thirteenth century, left behind him a rhyming chronicle. The subject is the history of England from the time of Brutus to the close of the reign of Henry III. The facts are chiefly taken from Geoffrey of Monmouth, and other old annalists. The verse consists of long lines of fourteen syllables, and abounds in Saxonisms. There is little of art or of spirit in the execution. The rhyme seems to cramp the verse, and to make it limp along at a duller pace than even ordinary prose. The Chronicle of Robert of Gloucester was printed by Hearn, in 2 vols. 8vo, Oxford, 1724, and reprinted at London in 1810.

ROBERT, *Léopold*, a distinguished French painter, was born in 1794, at Chaux-de-Fonds in Neuchâtel. From his earliest years a strong love for design characterized him. The commercial profession, to which he was apprenticed, was given up in disgust. He was not content until he was sent to Paris to study art. There he laboured with unwearied assiduity under Girardet the engraver and David the painter. Nor did his ardour abate when he found himself a poor and solitary student at Rome. The prosecution of his art was the only subject that he allowed to engross his mind. He patiently employed all the advantages of the place to perfect himself both in theory and in execution. He especially laboured to catch the traits of

Italian scenery, life, and character. The consequence of these devoted efforts was, that the connoisseurs in Paris were soon charmed with the fresh and faithful sketches which Robert sent home to the yearly exhibitions in the *salon* of the Louvre. Among others, his "Neapolitan Improvisator," in 1824; his "Madonna dell' Arco," in 1827; and his "Reapers," in 1831, continued to increase his reputation. He had attained the highest place in his own particular walk, and his latest work, "The Fishermen," was exciting great admiration in Paris, when the intelligence arrived that he had committed suicide at Venice in a fit of melancholy on the 20th March 1835.

ROBERTSON, WILLIAM, one of the most eminent of British historians, was born in the manse or parsonage of Borthwick, county of Edinburgh, on the 19th of September 1721. He was the eldest son of the Rev. William Robertson, minister of Borthwick, and of Eleanor, daughter of David Pitcairn, Esq. of Dieghorn. After nineteen years' ministry in the beautiful rural parish of Borthwick, Mr Robertson was appointed one of the ministers of Old Greyfriars church, Edinburgh, and, removing thither with his family, his son William was placed in the university at the early age of twelve. He had previously attended the popular grammar school of Dalkeith, then taught by a Mr Leslie. At the university William Robertson was distinguished for diligent and methodical study. He laid down for himself a strict plan of reading, and inscribed on his earliest note-books the motto *Vita sine litteris mors* ("life without letters is death"),—a remarkable instance of literary ambition in a youth of fourteen. He was also a conspicuous member of a society of his fellow-collegians, who met to cultivate elocution and extempore discussion. In his twentieth year Robertson was licensed to preach; and two years afterwards (1743) he was presented by the Earl of Hopetoun to the living of Gladsmuir, a country parish in Haddingtonshire. The presentation came at a fortunate time; for the same year the historian's parents died, within a few days of each other, of fever, leaving six daughters and one son almost wholly without provision. William removed the family to his manse at Gladsmuir, and renounced all idea of forming any matrimonial connection until he had seen them respectably settled in the world. This result was happily accomplished ere he had completed his thirtieth year; and in 1751 he married his cousin, Miss Nesbit, daughter of one of the ministers of Edinburgh. If we consider that the living of Gladsmuir was not worth more than L.100 per annum, the filial piety and generosity of Robertson in this critical period of his life must be held as constituting a moral claim on the regard and admiration of posterity, scarcely inferior to that of his literary renown. A similar principle of self-sacrifice and duty led him in the second year of his ministry at Gladsmuir to enrol himself in a body of volunteers formed to resist the Jacobite rising of 1745. He soon became known as an able preacher and debater in the church courts, his exertions being strenuously devoted to the maintenance of order and authority. "Having," as Lord Brougham remarks, "a very strong and clear opinion in favour of lay patronage, the great question which divided the Church of Scotland in that day, he assumed the lead of its advocates. At first they formed a small minority of the Assembly; but by degrees, reason, enforced by eloquence, had its course, and he gained ultimately a complete victory over his adversaries." In other words, the moderate party in the church obtained the ascendant, and this they maintained, though often assailed, for about ninety years. During the same time, however, dissent was gaining ground among the people; and at length the popular aversion to lay patronage led to the memorable disruption of 1843. The great merit of Robertson as an ecclesiastical leader was the regularity and order which he established in the church courts, en-

Robertson, forcing the exercise of the judicial power of the church, and investing the proceedings of the General Assembly with an interest and importance which they had never before possessed. He was a man of sagacity, penetration, and address,—active, intrepid, and eloquent,—“designed by nature, as well as formed by study, for a great practical statesman and orator.” These qualities were further displayed at the meetings of the “Select Society,” an association founded in 1754 by Allan Ramsay the painter and some of his friends, with the view of promoting philosophical inquiry, and the improvement of its members in public speaking. Adam Smith, David Hume, Wedderburn (Lord Loughborough), Lord Kames, John Home, Dr Carlyle, and other eminent and accomplished men were members of this society; and its friendly meetings, often terminating in small social supper parties, bound together the *literati* of Edinburgh, and gave a peculiar freedom and geniality to their intercourse. The evening meal—the Roman banquet—was long a favourite in Edinburgh. Men of study and men of business loved to relax over these familiar and inexpensive meetings; and the late Lord Cockburn has recorded that, “so far as he had seen social life, its brightest sunshine had been on the last repast of the day.” The modern late dinner in some degree occupies its place; but it is more costly, more cumbrous and formal, and infinitely less social and inspiring. Whatever the present generation may have gained in wisdom or in the minor morals of life, the art of conversation has certainly declined amongst us. Before Robertson had become one of the celebrities of the Scottish capital, he had engaged in historical researches, sitting in his quiet manse at Gladsmuir. In October 1753, we find him writing to Lord Hailes for information and books relative to the history of Scotland, as he intended to employ some of the idle time of that winter in making diligent inquiry into the period between the death of King James V. and the death of Queen Mary. In 1755 he published his only printed sermon, a discourse preached before the Society for promoting Christian Knowledge, and entitled *The Situation of the World at the time of Christ's Appearance, and its connection with the Success of his Religion Considered*. The historical bias of the author is thus manifested, and the sermon is as carefully and finely written, and as well reasoned, as any of his subsequent great works. In 1757 Robertson took an active part in defending some of his clerical friends from the persecution raised against them by the high Calvinistic party of the church, on account of Home's tragedy of *Douglas*. That a Presbyterian clergyman should write a play, was held to be a glaring scandal and outrage, and the offence was aggravated by the circumstance, that several of his brother ministers had been present at the representation of the tragedy in Edinburgh. Robertson was not of the number. He had early promised to his father that he would never enter a play-house; and though he rejoiced in the success of his friend's drama, and was delighted with private exhibitions of the genius of Garrick and Henderson, he faithfully kept his promise. Home bent before the clerical storm, by resigning his living at Athelstaneford, and most of the other clergymen having apologised and explained, were sentenced by their various presbyteries to short periods of suspension, or were only subjected to a rebuke. The pleas of alleviation put in by some of the offending ministers are amusingly characteristic. Mr White of Libberton owned the charge, but pleaded that he had gone to the play-house only once, and *endeavoured to conceal himself in a corner to avoid giving offence*. The presbytery suspended him from the 12th of January to the 2d of February. Mr Steel, minister of Stair, urged in extenuation that the play-house was at a great distance from his parish, and he had no reason to apprehend that he would be known! Not one of the ministers dared to justify his conduct in attending the

theatre, and all were much indebted to Robertson for the judgment and eloquence with which he conducted their defence. The incident is both an interesting and important one in the history of the Scottish Church; and it served to bring more prominently into notice the talents and principles of the rising minister of Gladsmuir. He was honoured with the degree of Doctor of Divinity by the university of Edinburgh; and in 1758 was appointed incumbent of Lady Yester's parish in Edinburgh. By this time he had brought his Scottish historical labours to a close, and he repaired to London to make arrangements for the publication of his work. Parts of it, while passing through the press, were shown to influential friends and patrons,—to the Duke of Argyle, Lord Royston, Horace Walpole, and others. The work was thus made the topic of conversation, and the author was enabled to obtain a satisfactory settlement with his publisher, Andrew Millar, who gave £600 for the copyright. In February 1759 appeared this first great work of Robertson in two quarto volumes, bearing the title of *The History of Scotland during the reigns of Queen Mary and James VI., till his accession to the Crown of England*. The most sanguine anticipations of the author and his friends were realized. Congratulations poured in upon the historian from all quarters. The London authors, he says, were astonished. Mr Doddington, Horace Walpole, Lady Hervey, and the Speaker of the House of Commons (the pompous Onslow), became his sworn friends. Lord Bute thought the work the first history in the English tongue. Lord Chesterfield compared Robertson to Livy. “Lord Lyttelton,” says David Hume, “seems to think that since the time of St Paul there scarce has been a better writer than Dr Robertson.” That want of idiomatic English which is now charged upon the historian was not discovered by the best masters of English of that day. Hume himself, though his own history had been far from successful, and though he was fully conscious of the powers and more popular qualities of his new rival, cordially recommended the work, and exerted himself to procure a good translation of it into French. All parties, political and literary, joined in the loud applause, and church preferment soon followed. Two months after the publication of the history, the office of chaplain of the garrison at Stirling fell vacant, and the historian received the appointment. In 1761 he was made one of the deans of the chapel-royal. In March 1762, on the death of Dr Gowdie, he was chosen principal of the university of Edinburgh and minister of the Old Greyfriars; and in 1764 the sinecure office of historiographer for Scotland was revived in his favour, with a salary of £200 per annum. The influence and nationality of Lord Bute are no doubt visible in these appointments, but they were all ratified by public opinion. The *History of Scotland*, both for what it did and what it promised, was well worthy of honour and reward. As a narrative, clear, luminous, and picturesque, of a most interesting and complicated portion of history, it has perhaps never been excelled. The style is too uniformly stately and measured, and a few Scotticisms may be detected; but in the delineation of character and the arrangement of incidents,—in moral reflection, acute remark, and sustained dignity of thought, and chaste embellishment, the work must ever rank in the first class of historical compositions, and will ever enchain the attention of the reader. The story of Mary, Queen of Scots, is told with inimitable grace and pathos; and although the views of Robertson have been assailed by eager and determined controversialists, no substantial deviation from the truth of history has been discovered in his work. The investigation of state papers, and the collection of Mary's letters and de-patches by Prince Labanoff, have since added to our stock of information; yet they have made no material alteration in the facts or deductions given by the Scottish

Robertson.

Robertson, historian.¹ Hume differs from Robertson in believing that Mary was accessory to the Babington conspiracy, including the intended assassination of Elizabeth; yet even this point is still only a matter of opinion or conjecture. The copy of the letter of Mary, on which the accusation is founded, is generally believed to have been altered from the original, and passages in it to have been interpolated by command of Walsingham, and no new evidence has been adduced. The same remark applies to the case of Mary and Darnley. What was obscure in the last century is obscure still. Ten years elapsed ere Robertson again appeared as an author. It had been suggested to him by the king, through the medium of Lord Bute, that he should undertake a History of England; and in the event of his compliance, every source of information which the government could command would be thrown open to him, with the addition of such a pecuniary provision as would enable him to bestow undivided attention on the work. The historian seems to have at first entertained the project, although declining to sever his connection with the Church of Scotland; but the retirement of Lord Bute and other causes led to the abandonment of the scheme. It is as well for Robertson's fame that he did not come into direct competition with his friend Hume, whose History was completed in 1761. In the most defective portion of Hume's history—the early period—Robertson would have been found equally deficient, in consequence of his ignorance of the northern languages; and though his diligence would have enabled him to avoid some of the palpable errors into which Hume fell, he would probably have entertained similar prejudices as to the Puritans and the Commonwealth, while he could hardly have hoped to excel his contemporary in philosophical analysis or grace of style. He more prudently selected a field still unoccupied; and in 1769 appeared, in three quarto volumes, *The History of the Reign of the Emperor Charles V., with a View of the Progress of Society from the Subversion of the Roman Empire to the beginning of the Sixteenth Century*. For the copyright of the work the historian received L.3600. "The character of Charles," as Dugald Stewart has observed, "was singularly adapted to Dr Robertson's purpose, not only as the ascendant it secured to him in the political world, marks him out indisputably as the principal figure in that illustrious group which then appeared on the theatre of Europe, but as it everywhere displays that deep and sagacious policy, which, by systematizing his counsels and linking together the great events of his reign, inspires a constant interest, if not for the personal fortunes of the man, at least for the magnificent projects of the politician. Nor is the character of Charles, however unamiable, without a certain species of attraction. The reader who is previously acquainted with the last scenes of his enterprising and brilliant life, while he follows him through the splendid

career of his ambition, can scarcely avoid to indulge occasionally those moral sympathies which the contrast awakens, and to borrow from the solitude of the cloister some prophetic touches, to soften the sternness of the warrior and statesman." It may be remarked, however, that the cloister life of Charles, as related by the historian, has been drawn from authorities of little value, and various errors have been pointed out in a recent work expressly devoted to this subject.² In the days of Robertson, minute research and collation of facts were held more subordinate than they are at present to the art of composition, and especially to the production of an interesting and glowing narrative; and the historian's account of Charles fully answered the public expectation, high as that had been raised by his previous History. The first volume of the work contains a view of the progress of society, and is an admirable philosophical dissertation on that important period of the world's history, when, as the author himself observes, "the several powers of Europe were formed into one great political system, in which each took a station, wherein it has since remained with less alteration than could have been expected, after the shocks occasioned by so many internal revolutions and so many foreign wars."

After an interval of eight years, Dr Robertson published, in 1777, his *History of America*, in two volumes quarto. His popularity was still undiminished, and his publisher was glad to secure the work by a payment of L.2400 for the copyright, being in the same proportion as the sum given for the *History of Charles V.* The narrative portion of the *America* contains perhaps the finest passages in all Robertson's works. He has nowhere else shown the same power of picturesque and striking description. His imagination was excited by the great event of Columbus's voyage, the simple majestic character of the adventurous discoverer, and the landing and meeting with the natives, who regarded their new guests "as a superior order of beings, children of the sun, who had descended to visit the earth." The elements of the highest order of poetry are comprised in the incidents and general character of this great discovery of the New World; and Robertson has produced a series of grand historical paintings to which only the writings of Macaulay can furnish a parallel.³ One blemish in Robertson's work has been justly censured by his biographer, Dugald Stewart, though it is unfelt by the reader while carried along by the deep interest of the narrative. We refer to the disposition which the historian has shown to palliate or to veil the enormities of the Spaniards in their American conquests. The acquisition of the New World, it is calculated, was effected by the murder of 10,000,000 of the human species; and the accounts of this enormous carnage are authenticated beyond the possibility of dispute. "Millions died that Cæsar might be great," says the poet;

¹ In one small point, a personal feature of Mary—and the Queen's person is a circumstance not to be disregarded, as Robertson has said, in the history of a female reign—a correction may be noted. The historian states that Mary's hair was *black*; in reality it was *auburn*, inclining to a dark red. The portraits of Mary of Guise have often been mistaken and engraved for those of her daughter Mary, Queen of Scots.

² *The Cloister Life of the Emperor Charles the Fifth*, by William Stirling, London, 1852. Mr Stirling has derived his materials from the *History of the Order of St Jerome*, by Joseph de Siguença, who was born in 1545,—a work of which Robertson does not seem to have heard,—and from MSS. in the archives of the French Foreign Office. Mr Stirling's volume is a curious and valuable contribution to history.

³ Lord Brougham—the grandson of Dr Robertson's sister—has instituted a parallel, or rather contrast, between parts of Robertson's History and parts of Mr Washington Irving's work, *The Life and Voyages of Columbus*. In chaste simplicity of style, combined with dramatic effect, the superiority undoubtedly rests with the Scottish historian. We give one of Lord Brougham's passages of comparison:—"About two hours before midnight, Columbus, standing on the fore-castle, observed a light at a distance, and presently pointed it out to Pedro," &c. Thus Robertson. Irving says:—"Wrapped from observation in the shades of night, he maintained an intense and unrelenting watch, ranging his eye along the dusky horizon. Suddenly about ten o'clock he thought he beheld a light glimmering at a distance." Lord Brougham (who remarks that Robertson had never thought of saying "suddenly," as knowing that light must of necessity be sudden), triumphantly asks, "Can any one doubt which of the two passages is the most striking—the chaste and severe, or the ornamented and gaudy and meretricious? The account of Robertson makes the ships lie-to all night. Irving either makes them lie-to, and afterwards go on sailing rapidly, or the lying-to was the night before, and they sailed quicker the nearer they came to land, and in the dusk. The one makes them only see the shore after dawn; the other makes them see it two leagues off, in a dark night, at two in the morning, within the tropics." (Brougham's *Lives of Men of Letters*, London, 1845, page 296.) This minute verbal criticism is worthy of Johnson. Lord Brougham's own writings would ill stand such a test.

Robertson, and every conqueror from Nimrod to Napoleon has been equally careless of the death, desolation, and misery occasioned by wars of ambition. Robertson should have branded the inhuman excesses of the Spaniards with his eloquent indignation. In his own nature and sentiments he was humane and enlightened; but he appears, like others, to have been captivated and blinded by the romance of his theme, and by the grand poetical enterprise of discovering and securing a new hemisphere. Shortly after the publication of his American history Robertson evinced his sense of justice and his principles of enlightened toleration by supporting the repeal of part of the penal laws against the Roman Catholics, which had been abolished in England, but were still in force in Scotland. The statute conferred no political rights on the Roman Catholics; from these they were debarred until half a century more had elapsed. The Papist, as Robertson said, "had not acquired the privileges of a citizen; he was only restored to the rights of a man." He was rendered capable of inheriting property by succession or conveyance, of transmitting it to others, or of acquiring it by purchase; and the Roman Catholic ecclesiastics who should take upon them the instruction of youth were freed from the dreadful penalty of perpetual imprisonment. This mild relaxation of the persecuting laws was resisted by a large body of the clergy and people of Scotland. Riots took place in Glasgow and Edinburgh; in the latter a house supposed to contain a Popish chapel was burned to the ground, and another house occupied by a Roman Catholic clergyman was destroyed. At night an attack upon the residence of Dr Robertson was meditated, but by that time some troops of dragoons had arrived, and a military party was posted in the college court, which prevented further violence. This disgraceful outburst of fanaticism (which cost the city of Edinburgh a sum of £1650 by way of indemnification) probably hastened the intention of Robertson to retire from public life. He was now verging on his sixtieth year, and incessant study, as well as public business, had impaired the vigour of his robust constitution. His literary labours, however, were not terminated until the year 1791, when he published *An Historical Disquisition concerning the Knowledge which the Ancients had of India*. The perusal of Major Rennell's Memoir for illustrating his map of Hindustan suggested this inquiry, which is marked by the author's wonted diligence in collecting and arranging materials, and by his skill in perspicuous narrative and illustration. The old age of the historian was cheerful and happy. There had been no death in his family. One son had adopted the legal profession (he afterwards rose to be a judge of the Court of Session), and two other sons had entered and distinguished themselves in the army. His eldest daughter was married to Mr Brydone, author of the well-known *Tour through Sicily and Malta*; and at Mr Brydone's residence of Lennel, on the southern border, the historian, we are told, delighted to pass a few weeks of summer or autumn. Latterly he resided at Grange House, near Edinburgh; and Lord Cockburn, in his *Memorials of his Time*, has given a graphic account of the "Principal," as he was usually styled from his office in the university:—

"Many a happy summer day had his grandson John Russell and I in that house (the Grange). The doctor used to assist us in devising schemes to prevent the escape of our rabbits; and sometimes, but this was rarely, and with strict injunctions to us to observe that moderation which Mrs Robertson could never make himself practise, he permitted us to have a pull at his favourite cherry-tree. He was a pleasant-looking old man, with an eye of great vivacity and intelligence, a large projecting chin, a small hearing-trumpet fastened by a black ribbon to a button-hole of his coat, and a rather large wig, powdered and curled. He struck us boys, even from the side-table, as being evidently fond of a good din-

ner; at which he sat with his chin upon his plate, intent upon the real business of the occasion. This appearance, however, must have been produced partly by his deafness; because when his eye told him that there was something interesting, it was delightful to observe the animation with which he instantly applied his trumpet; when, having caught the scent, he followed it up, and was leader of the pack."

This familiar sketch, like a Dutch painting, brings the domestic scene and its leading figure distinctly before us. Lord Brougham gives a few additional touches. The historian always wore his cocked hat even in the country; he had a stately gait, a slight guttural accent in his speech, which gave it a peculiar fulness; and he retained some old-fashioned modes of address, as using the word "Madam" at full length; and when he drank wine with any woman, adding "My humble service to you." Johnson thought Robertson a poor talker; but the sage of Bolt Court had exaggerated ideas as to the standard of good conversation, which with him was a species of intellectual gladiatorship. By all his familiar friends the historian was esteemed as an agreeable and instructive companion, and Dugald Stewart mentions the "splendid variety of his conversation." Until within a few months of his decease Dr Robertson continued to preach; and his sermons, delivered with the aid only of a few notes, are described as having been at once simple, correct, and impressive. He was no deep evangelical divine, and doubts have even been hazarded as to his orthodoxy, to which his long and intimate friendship with David Hume may have first given rise. That friendship, he said, he always considered as one of the most fortunate and honourable circumstances of his life. "It is a felicity of the age and country in which we live, that men of letters can enter the same walk of science, and go on successfully, without feeling one sentiment of envy or rivalry. In the intercourse between Mr Hume and me (he writes to Gibbon), we always found *something to blame* as well as *something to commend*. I have received frequently very valuable criticisms on my performances from him; and I have sometimes ventured to offer him my strictures on his works. Permit me to hope for the same indulgence from you." The style of Robertson's letters to Gibbon is more open to censure than any uncharitable inference which can be drawn from his intimacy with Hume. His position in the church and in the university demanded that he should at least have remonstrated against the two memorable and insidious chapters in the *Decline and Fall* on the subject of Christianity. But his language to Gibbon is uniformly complimentary; and instead of joining with Lord Hailes and Bishop Watson in denouncing the tone and spirit of the English historian, he speaks of the bigotry and fierce Christianity of parties who opposed him. The explanation is, that Robertson was a man of the world as well as a man of letters. In the former character he was apt to be over-complaisant, and in the latter he regarded literary success as the great business and absorbing pursuit of life. The historian at times overpowered the divine. He was also reserved and reticent—an admirer of the school of Stoics. His deepest feelings lay hid from common observation. He would not, like Swift, have read prayers before his stranger guests had risen from their beds, but he would have importuned none of them to be present. There is not, however, a shadow of evidence to prove that Robertson ever disbelieved the faith of his fathers. His pastoral duties were discharged with exemplary care and regularity, and he preserved through life the confidence and regard of several of his brother divines, the most eminent for piety and strictness of Presbyterian doctrine and discipline. The health of Dr Robertson began to fail in the end of the year 1791, when symptoms of jaundice appeared, and a long and lingering illness succeeded. "While he was able to walk

abroad," says Dugald Stewart, "he commonly passed a part of the day in a small garden, enjoying the simple gratifications it afforded with all his wonted relish. Some who now hear me will long remember, among the trivial yet interesting incidents which marked these last weeks of his memorable life, his daily visits to the fruit-trees (which were then in blossom), and the smile with which he, more than once, contrasted the interest he took in their progress with the event which was to happen before their maturity." He died on the 11th of June 1793, in the seventy-second year of his age. His funeral sermon was preached by his colleague in the church, Dr Erskine, who, though opposed to Robertson in his views of ecclesiastical government and policy, bore ample testimony to the talents and virtues of his friend, and who has left this record of his moral qualities:—"He enjoyed the bounties of Providence without running into riot; was temperate without austerity; condescending and affable without meanness; and in expense neither sordid nor prodigal. He could feel an injury, and yet bridle his passions; was grave, not sullen; steady, not obstinate; friendly, not officious; prudent and cautious, not timid."

(R. C.—S.)

ROBERVALLIAN LINES, a name given to certain lines used for the transformation of figures, so called from Roberval, the inventor of them. These lines are the boundaries of lines infinitely extended in length, yet equal to other spaces which are terminated on all sides. It is observed by the Abbé Gallois, that the method of transforming figures, which is explained at the end of Roberval's treatise of Indivisibles, was the same with that afterwards published by James Gregory in his *Geometria Universalis*, and also by Dr Barrow in his *Lectures Geometricæ*; and that it appears from Torricelli's letter that Roberval was the inventor of this method of transforming figures, by means of certain lines called by Torricelli, for that reason, Robervallian lines. The same author adds that J. Gregory probably first learned this method at Padua in the year 1668; for the method was known in Italy in 1646, although the book was not published till 1692. David Gregory endeavoured to refute this account, in vindication of his uncle James. His answer appeared in the *Philosophical Transactions* for 1694, and Gallois rejoined in the *Memoirs* of the French Academy for 1703; so that it remains in a state of uncertainty to which of the two we are to ascribe the invention.

ROBESPIERRE, FRANÇOIS-MAXIMILIEN-JOSEPH-ISTOIRE DE, a political fanatic of the French Revolution, was born in the town of Arras in 1758. His family is reported to have come from Ireland at a very early period, and, according to a plausible conjecture of his biographer G. H. Lewes, the original name was in all probability Spiers. His father was a successful advocate at Arras, who seems to have deserted his four children in infancy, shortly after the death of their mother. Maximilien was the eldest of this household; and at the age of ten or eleven he found himself the guardian of his brother and sisters. Having given marks of ability at the college of Arras, the bishop placed him on the foundation of the college of Louis-le-Grand. Robespierre repaired to Paris in 1770. Here he had for his class-fellows the fierce, vehement, and generous Danton, the witty, prompt, and reckless Desmoulins, afterwards destined to run the same terrible race with himself, and whom by his craft he was to overthrow; besides Fréron, who was one day to become the people's orator. Heedless as yet of Jacobin or Gironde, these generous boys played beneath the dismal college walls, and made the whole region echo to their loud and happy voices. The sunlight was slow to welcome them behind those high, dingy buildings; but could not they dispense with this privilege, when they could illuminate their inclosure with the rosy laughter of health and youth? Robespierre, who was bilious and

melancholy, was more given to study than play. Especially did he devote great attention to the languages and history of Greece and Rome. His master Hérivaux called him "the Roman." After spending eight years at this institution, he commenced the study of jurisprudence at L'Ecole de Droit. Here he led a life of honourable poverty, seclusion, and study, heedless of the aristocracy, who danced there far into the morning, and whose ladies "violated," according to Sydney Smith, "all the common duties of life, and gave very pleasant little suppers;" heedless of the atheists, with their endless jargon about "eternal progress;" heedless, likewise, of the sceptics, with their wild enthusiasm about charity, fraternity, and equality.

The *Contrat Social* of Rousseau (1762) was the bible of the Revolution. Assumed at first as the richer field for displaying "eloquence and philosophy," Rousseau gradually consummated his metaphysical paradox, and appeared in this work as the earnest expounder of a thoroughly earnest creed. Its fundamental idea, that society is a contract made by all for the good of all, is probably the most revolutionary dogma ever enounced. Yet this was the dogma which Robespierre, and thousands with him, embraced with enthusiasm; this was the major premiss which he spent his life in ardently evolving. His was not a circumspect mind; once he had satisfied himself of the truth of his preliminary, he afterwards held on his course with the most logical and even fatal pertinacity. His term completed, Robespierre returned to Arras, and began practice. In 1783 a landed proprietor had erected a lightning-conductor on his property, much to the scandal of the discreet citizens of Arras. "Deistical philosophy; away with it." Robespierre was chosen the advocate to plead this case; and he had the gratification, when the trial came on, to find himself completely triumphant. This cause tended materially to extend the fame of the young advocate. He was admitted a member of a poetical society called "Les Rosatis;" actually aspired to be a poet, and seems to have fallen (not very desperately) in love. Meanwhile he became a member of the criminal court, an office which he shortly afterwards resigned from opposition to capital punishment; took a very decided part against the clergy and the lords of Artois concerning the Artesian Third Estate; chose rather to lose the friendship of the Bishop of Arras than prove false to Rousseau and his own blind logic. The peasantry already came to him as to the friend of the people. The Tiers-Etat of Artois chose him as their deputy to the States-General. In 1789 he again betook himself to the French capital, and enjoyed the pleasure of beholding the poor, feeble, good-natured king enter the States-General emblazoned in all the splendour of royalty. Robespierre even ventured to make a motion before this assembly of the notables; but who could listen to this obscure individual, with his cracked voice and uncongenial aspect? He had neither the advantages of birth, of genius, or of exterior, to arrest men's notice. His figure was small; his limbs feeble and angular; he walked with an irresolute step; bore himself with affected attitudes and ungraceful gestures; his forehead was small and projecting; his blue eyes were soft, sinister, and sunken; his complexion "sea-green;" and his temperament "atrabiliar." His whole features, like the whole of his mind, converged incessantly on a point. It was on this point, and around this point, that his faculties ceaselessly played; and, as his career subsequently proved, he was ready to sacrifice heaven and earth to his convictions. He was the very embodiment of the Revolution in principles, in passions, and in impulses. The States-General would not at present listen to his shrill logic; but the day was not far distant when its harsh sounds should reach their ears. Meanwhile Robespierre was a royalist, as indeed were the whole of the Assembly. The Third Estate gained its point; the States-General became the National Assembly; and all men ran to

Robes-
pierre.

Robes-
pierre.

and fro in the streets of Versailles the whole of the last night of June with shouts and jubilation.

From the date of Robespierre's speech on the declaration of the rights of man we may date his republicanism. Rousseau's philosophy was now beginning to operate; and in pursuing its conclusions, Robespierre found that it carried him quite beyond the bounds which time and circumstance had assigned to royalty. The eagle eye of Mirabeau had already scanned him, and seized upon the ruling element in his character. "He will go far," says Mirabeau, "for he believes all he says."

On the 19th of October the Assembly was transferred from Versailles to Paris; and "Le Club Breton," of which Robespierre was a member, on taking up its abode in the convent of the Jacobins, was henceforth known as the Jacobin Club. Some 1300 chosen patriots, among whom were Barnave, Mirabeau, and the two Lameths, here met to deliberate. This was the theatre on which the peculiar power of Robespierre was subsequently to be displayed. Meanwhile his speeches are by no means striking. His language, unrelieved by any play of fancy, was pedantic and heavy; he was a logician and not an orator; what he said has the merit of consistency, and it hangs well together. He gradually, in his stern advocacy of justice, had constituted himself the protector of the oppressed. His great vanity was immensely flattered by the congratulatory letters which followed his endeavour to do away with the celibacy of the clergy. Speaking of those letters, he remarked to Villiers, "People talk of there being no poets; you see I can make some." This thirst for popular applause was fatal to him. It led him to flatter the mob; it led him to spice his convictions to the taste of his auditory; it led him to cringe when he ought to have ruled, and to deal in adroit enigmas when he should have enlightened. The Jacobin newspapers, those journals that daily bespattered him so thickly with praise, styled him "the incorruptible;" but they forgot that there was even a worse, because a more subtle, corruption than that engendered by the love of gold,—the corruption which consists in not having courage to be true. Robespierre was very frugal, and had scarcely money enough to purchase clothes. When the Assembly decreed a general mourning for the death of Franklin, he was obliged to borrow a black stuff coat, which was so large for him that "it dragged on the ground."

Mirabeau was now dead. A vacancy was left for Robespierre in the Assembly, which he no sooner occupied than he addressed himself to its members in a tone that was new, audacious, and almost imperious. "Here is the essential instruction which I lay before the Assembly," was the authoritative language adopted by the timid deputy. Robespierre had now become what Foucauld, in the earlier stages of his career, had sarcastically called him,—"the tribune of the people." On the 10th of May he proposed, and caused to be decreed, that "the members of the present Assembly cannot be elected for the next legislature." Shut out by his own act from the National Assembly, he directed his sole attention to the Jacobin Club. The tribune of the people knew well where the life and strength of the legislature rested,—where the thunders of the populace securely lay. Robespierre is now a rising man, and he must of course walk warily. A curious discussion took place in the National Assembly on the 30th of May regarding the momentous question, the punishment of death, where Robespierre made a very important speech, in which he tried to prove that such an institution was essentially unjust. And let it not be supposed that in so doing he played the hypocrite; it was a serious conviction with him, dating pretty far back. And when such are the patriot's opinions, nay convictions,—can it be wrong in an assembly to appoint him public accuser? Dupont and Bigot refused office under Robespierre, assigning as their reason that he

was a violent man (*un homme sans mesure*). But is he not an "incorruptible" patriot, firm in his principles, and deaf to all considerations? So reasoned Biissot.

Robes-
pierre.

The work of the Constituent Assembly finished, and its successor, the Legislative Assembly, chosen, Robespierre, in the month of October 1791, resolved to improve the interval by a visit to his native town of Arras. His entry was an ovation. Old men with civic crowns, attended by maidens robed in spotless white, and troops of children scattering flowers, stood ready to receive the cortège. Thus rode the proud and bilious patriot into his natal city, from which, not many years ago, he had gone forth an obscure provincial lawyer. On his return to the Jacobin Club, he had a disagreeable quarrel with the Girondins, to whom he, from that hour to the day of their fall, entertained the very strongest dislike. Men began now to be painfully aware of his ambition, and accused him of aspiring to a dictatorship. The 10th of August closed with the dethronement of the king, and the formation of the National Convention. A revolutionary tribunal was formed, and Robespierre was appointed one of the judges. He was not, however, as he has been constantly accused of being, a sharer in the horrors of that fearful massacre. Robespierre was essentially a timid man, and ventured on no occasion to oppose a riot, however he might choose to oppose an idea. All that he can be charged with on that September massacre is, that he withheld his enormous influence with the people to arrest that terrible riot of blood and vengeance. Robespierre could flatter the people to fury; but when it came to action, he skulked out of sight, and allowed Danton to control them. On the 29th of October Louvet hurled his tremendous philippic at the head of Robespierre. "I accuse you," said Louvet, "of having constantly put yourself forward as an object of idolatry; of having suffered yourself to be designated, in your own presence, as the only virtuous man in France who could save the people, and of having said so yourself; I accuse you of having aspired to supreme power," &c. But Robespierre, who had the mob on his side, could as yet afford to smile at such charges, and accordingly his reply was a triumph. "What is virtue," said Camille Desmoulins, "if Robespierre be not its image?"

The poor king, meanwhile, is dragging out his few remaining days in solitary walks about the Temple garden. France loudly demands his trial; and what France really wants, is it to be supposed Robespierre will refuse? On the 21st of January 1793 the head of "the tyrant" accordingly falls; and Robespierre trumpets his own praises loud in the ears of men. Shortly afterwards the Gironde fell; the Committee of Public Salvation was established; and Robespierre was chosen one of the decemvirs. He will now have to act rather than declaim,—to do rather than to criticise. He has now become a minister, almost a dictator; and men are now to see whether he who has theorized so well has any faculty in him for action. "No," he says subsequently, and very significantly, "I was not made to rule; I was made to combat the enemies of the people." Marie Antoinette and Philippe Egalité were among the foremost victims of the Reign of Terror. The guillotine was literally lubricated with human blood. Innocent women, simple boys, and feeble men, all were dragged to satisfy the vehemence of the blood-thirsty populace. Hébert was got rid of at the Commune; Danton, that man of gigantic powers, at the Convention; and Camille Desmoulins had to give over for ever his *Vieux Cordelier*. Robespierre is now master of the Revolution; but were not these last three who have fallen men also popular? Times are becoming rather critical now even for incorruptible patriots. On the 7th of May 1794 Robespierre gained for himself immense applause by his address on the relation between religious and moral ideas and republic in principle. With him the idea of "*l'Être Suprême*" had always been

Robins. fundamental; and now, on the 8th of June, was transacted that piece of colossal folly, so essentially French, known as the *Fête de l'Être Suprême*. His part in that feast was very godlike; but it ruined him with the Convention. He became, meanwhile, weary of the Terror, and would have it repealed; but the Convention saw through his policy. Robespierre ceased to frequent their committees, and directed all his efforts towards the Jacobins. The conspiracy of the "Thermidorians," as it was called, meanwhile, made progress; but Robespierre's language was vague, obscure, and ambiguous. He vacillated between secret suspicion and open accusation; his mind was evidently ill at ease; but the question was, how could he evade their wrath? He vehemently declaimed against them at the Convention; but it would not do. Again he strove to obtain a hearing, but to no purpose. The Mountain treated him with contempt, the Girondins with bitter scorn. He yelled till he grew hoarse, when some one called out, "The blood of Danton chokes you!" He sneaked, "President of Assassins! will you let me speak?" But his doom was sealed; they would no longer hear him. The decree for his arrest was voted amid shouts of "*Vive la République!*" He was borne, together with Lebas, St Just, and Couthon, to the Hotel de Ville. Boudon and Doulac, with gendarmes and soldiers, penetrated during the night to where the prisoners lay, when Meda (so goes the story) levelled his pistol at the tyrant, and shot away the left side of his face. In the afternoon of the following day the prisoners were borne on carts to the Place de la Revolution. Robespierre mounted the ladder with a firm step; down clanked the axe, as was its wont; his head rolled into the basket; and thus, on the 28th of July 1794, in his thirty-fifth year, this singular mystery of a man passed away into eternity.

In 1832 Lapponetie published the *Œuvres Choies* of Robespierre. Among the numerous biographies and histories which represent the character of this strange being, we may cite the histories of Carlyle, Michelet, Thiers, Mignet, Alison, Louis Blanc, and Lamartine. Probably the most unbiassed account of him will be found in the *Life of Maximilien Robespierre*, by G. H. Lewes, 1849. (J. D—S.)

ROBINS, BENJAMIN, an ingenious mathematician, was born at Bath in 1707. His parents were Quakers of humble condition, and consequently were unable to give him much instruction; but his own propensity to science having procured him a recommendation to Dr Pemberton in London, he acquired from him the higher parts of mathematical knowledge. He for some time taught mathematics; but not finding it suitable to his taste, he gave it up, and engaged in various interesting and laborious experiments in gunnery. While thus occupied, he was led to consider the mechanical arts that depend on mathematical principles, as the construction of mills, the building of bridges, the draining of fens, the rendering of rivers navigable, and the making of harbours. Fortification much engaged his attention; and he met with opportunities of perfecting himself in this branch of knowledge by viewing the principal strong places of Flanders, in some tours which he made with persons of distinction. Upon his return from one of these excursions, he found the learned amused with Dr Berkeley's work entitled *The Analyst*, in which an attempt was made to explode the method of fluxions. Robins was therefore advised to clear up this subject by giving a distinct account of Sir Isaac Newton's doctrines, so as to obviate all the objections that had been made without naming them. Accordingly he published in 1735 *A Discourse concerning the Nature and Certainty of Sir Isaac Newton's Method of Fluxions*; and, some exceptions being made to his manner of defending Newton, he afterwards wrote two or three additional discourses. In 1738 he defended the same great philosopher against an objection contained in a

note at the end of Baxter's *Matho, sive Cosmotheoria puerilis*; and the following year printed *Remarks on Euler's Treatise of Motion*, on Dr Smith's *System of Optics*, and on Dr Jurin's *Discourse of distinct and indistinct Vision*, annexed to Smith's work. In the meanwhile, Robins did not solely confine himself to mathematical subjects; for in 1739 he published, without his name, three pamphlets on political affairs. Two of them, relating to the convention and negotiation with Spain, were so highly esteemed as to occasion his being employed in a very honourable post; on a committee being appointed to examine into the past conduct of Sir Robert Walpole, he was chosen their secretary.

In 1742 Robins published a small treatise entitled *New Principles of Gunnery*, containing the result of many experiments; and a discourse being published in the *Philosophical Transactions*, in order to invalidate some of his opinions, he thought proper, in an account which he gave of his book in the same *Transactions*, to take notice of those experiments. In consequence of this discussion, several of his Dissertations on the resistance of Air were read, and the experiments exhibited before the Royal Society, for which he was presented by that honourable body with a gold medal.

In 1748 appeared Lord Anson's *Voyage round the World*, which, though Walter's name is in the title, has been generally thought to be the work of Robins. Walter, chaplain on board the Centurion, had brought it down to his departure from Macao for England, when he proposed to print the work by subscription. It was, however, it is said, thought proper that an able judge should review and correct it, and Robins was appointed; when, upon examination, it was resolved that the whole should be rewritten by Robins, and that Walter's papers should only serve as materials. Hence the introduction entire, and many dissertations in the body of the work, it is said, were composed by him, without receiving the least assistance from Walter's manuscript, which chiefly related to the wind and the weather, the currents, courses, bearings, distances, the qualities of the ground on which they anchored, and such particulars as generally fill up a sailor's account. No production of this kind ever met with a more favourable reception; four large impressions were sold within a twelvemonth, and it has been translated into most of the languages of Europe. The fifth edition, printed at London in 1749, was revised and corrected by Robins himself. In the corrigenda and addenda to the first volume of the *Biographia Britannica*, printed in the beginning of the fourth volume of that work, it is, however, stated that Robins was only consulted with respect to the disposition of the drawings, and that he had left England before the book was printed. Whether this be the fact, as it is asserted to be by the widow of Walter, it is not for us to determine.

Robins was soon afterwards desired to compose an apology for the unfortunate affair at Prestonpans. It was prefixed as a preface to *The Report of the Proceedings of the Board of General Officers on their Examination into the conduct of Lieutenant-General Sir John Cope*; and this preface was esteemed a masterpiece in its kind. He afterwards, through the interest of Lord Anson, contributed to the improvements made in the Royal Observatory at Greenwich. Having thus established his reputation, he was appointed engineer-general to the East India Company. He arrived in the East Indies in 1750; but the climate not agreeing with his constitution, he died there the year following.

ROBINS, or Robyns, John, an old English astronomer, was born in Staffordshire about the beginning of the sixteenth century, and was educated at Oxford for the church. His almost unrivalled excellence in "the pleasant

Robins.

Robinson. studies of mathematics and astrology" introduced him in course of time to the favour of royalty itself. Henry VIII. made him canon of his college in 1532, and canon of Windsor in 1543. Queen Mary also appointed him her chaplain, and continued to hold him in great respect till his death in 1558. Robins is now known by several treatises in manuscript. His *De Portentosis Cometis* may be seen in the British Museum; and his *De Culminatione Stellarum Fixarum*, his *De Ortus et Occasu Stellarum Fixarum*, and a part of his *Annotationes Astrologice* are preserved in the Bodleian Library. (Wood's *Athenæ Oxonienses*.)

ROBINSON, ROBERT, an eminent minister of the Baptist denomination in the last century, was born at Swaffham in Norfolk, January 8, 1735. His father, Michael Robinson, was an officer in the excise, and led a profligate life. His mother, whose maiden name was Mary Wilkin, was a woman of superior intelligence and piety. In her early days she must have possessed much personal beauty, for her son describes her as "having at ninety the complexion and vivacity proper to seventeen." She endured with exemplary patience her father's harshness and her husband's dissoluteness, and was thrown by both on her own resources to support herself and her family. Robert was her youngest son, and, to use her own words, "grew up a pretty scholar." His parents left Swaffham when he was seven years old, and he had then been learning Latin a year and a half, much to his master's satisfaction, who declared that he never knew a child with such a capacity. At Scarning, their next place of residence, was an endowed grammar school, to which Mary Robinson, by taking in needle-work and keeping a lodging-house (her worthless husband having absconded), was enabled to send her son: among his school-fellows was Thurlow, afterwards lord chancellor. Robert's attainments in classical learning and French were above the average, but unfortunately the mathematics, and even common arithmetic, were not taught. As he had not the means of going to college, or entering a profession, he was apprenticed at the age of fourteen to a hair-dresser in London, who took him without a premium. We are told of him at this time that he was more employed in reading than in working, in hearing noted preachers than in attending customers; but his master treated him with liberality and kindness, and having the sense to perceive that he was fitted for a higher calling, returned his indentures before his apprenticeship expired. He was in the practice of early rising to pursue his studies,—an invaluable habit which he inherited from his mother, who at the age of eighty and upwards rose regularly at four. In later life he injured himself by night studies, and boasted that he was master of the twenty-four hours. Nature, however, resented this infringement of her rights, and his constitution was broken and hastening to decay at the comparatively early age of fifty-four.

Dr Gill among the Dissenters, and Mr Romaine in the Established Church, were his favourite preachers: but he always regarded George Whitefield as his spiritual father, and in the early part of his religious profession ranked himself among his followers. He appears to have entertained the idea of being a preacher when only nineteen, and, in order to acquire fluency of expression, used occasionally to preach for an hour together in his own room to himself. He preached to a numerous auditory in the Tabernacle at Norwich, and at other places in the neighbourhood. After a while, he left the Calvinistic Methodists, and with thirteen other persons formed a congregational church in the parish of St Paul, Norwich, and became their settled pastor. Having renounced Pædobaptism, he was invited to a Baptist congregation at Cambridge in 1759, and, after a trial of two years, became their pastor in the spring of 1761. In a worldly point of view, his prospects were the reverse of flattering. He had not received above ten guineas from his own family for some years; his maternal grandfather had cut him off with a legacy of half-a-guinea; his wife (for he was now a married man) brought him only £100, and his first half-year's salary was under £14. Besides, the congregation, through the misconduct of many of its

former members, had acquired a bad character. "These," he said, "would have been insurmountable difficulties to an elder and a wiser man; but he was a boy, and the love of his flock was a million to him." He preached twice, sometimes three times, every Sunday at Cambridge, and during the week at one or other of sixteen villages in the neighbourhood. In a few years a new and commodious meeting-house was erected; members of the university were attracted to it, and attendance at the dissenting chapel became a pleasant lounge for the under-graduates; some of them, however, behaved so indecorously as seriously to annoy the congregation, and on one occasion obliged it to disperse without concluding the service. A memorial was addressed to their tutor, and an acknowledgment was inserted by the chief offender in the newspapers. But a still severer chastisement was inflicted by Robinson himself in "A Lecture on Becoming Behaviour in Religious Assemblies," delivered on Sunday evening, January 10, 1783, and afterwards published. His "speech" on this occasion certainly did not "distil as the dew," but fell on the head of the culprits like a shower of molten lead. Take this sentence as a specimen:—"Should that question, sometimes put up in the schools, be ever put up in a circle of ladies, *Detur vacuum* (is there an empty place in nature?) they would be provoked to answer, *Detur*. It is in the brain of him who behaves ill at divine worship." In 1773 he removed from the village of Hauxton—where, before he left, he had nine children, a wife, and an aged mother to support—to Chesterton, 2 miles from Cambridge. Here he at first hired, and in 1775 purchased a house; gradually he acquired land enough to carry on the business of a farmer and coal-merchant: these purchases he was enabled to make partly by the proceeds of his literary labours, and partly by the generous aid of one or two ardent admirers. He scouted the notion of its being a violation of clerical propriety to engage in secular pursuits: "Godly boobies," he would say, "too idle many of them to work, too ignorant to give instruction, and too conceited to study, spending all their time in talking and mischief, are these the men to direct my conduct, to censure my industry?"

Robinson began his literary career at Hauxton by publishing a specimen of a translation of Saurin's Sermons. The first volume appeared in 1775, and was followed by three others. In 1784 a new edition was published, with an additional volume. His *Plea for the Divinity of our Lord Jesus Christ* was very favourably received, and procured the author many compliments from dignitaries in the Establishment. Offers were made to him of preferment in the church, which he modestly but firmly rejected. When asked by Dr Ogden, "Do the dissenters know the worth of the man?" his answer was, "The man knows the worth of the dissenters." In 1774 he published, anonymously, a series of letters entitled *Arcana, or the Principles of the late Petitioners to Parliament for Relief in the matter of Subscription*, which increased his reputation among the Nonconformists. Two smaller works, *The History and Mystery of Good Friday*, and a *Plan of Lectures on Nonconformity*, were widely circulated, and soon passed through several editions. These were followed by a translation of Claude's *Essay on the Composition of a Sermon*, with a clever dissertation, and a body of very curious notes. For this he received £400. Besides various single sermons and pamphlets, he published a volume of *Seventeen Discourses on several Texts of Scripture, addressed to Christian Assemblies in Villages near Cambridge, to which are added Six Morning Exercises*. They are marked by great originality and ingenuity; and if they have not preserved the popularity which they at first obtained, it may perhaps be accounted for by their ambiguousness and vacillation in doctrinal sentiment, which became a characteristic of the author, and increased to the close of his life. Symptoms of this may be found even in his *Plea*; and it is the opinion of his biographer, that at the time of writing this treatise he was not clear from embarrassment on the very thesis he had undertaken to defend. In 1781 Robinson was requested by a number of the leading Baptists in London to write a history of the denomination, and arrangements were made for his visiting London every month, in order to consult books and manuscripts at the British Museum, of which Dr Clifford, a Baptist minister, was then sub-librarian; but after making the experiment, he found

Robison. that he could carry on his researches more easily at home. From that time to his death he devoted himself to the undertaking with an intensity of application that no doubt shortened his days. In order to acquire information for this and another historical work, he studied Italian, German, Spanish, and Dutch.

His *History of Baptism*, a quarto volume of above 650 pages, was published a few weeks after his death, and one of his last letters refers to a correction of the proof-sheets. His *Ecclesiastical Researches*, a quarto volume of about the same size, was published by subscription (like the former) in 1792.

For some months previous to his death Robinson had been in a declining state, prostrated both in body and mind. On Wednesday, June 2, 1790, he set off from Chertonton on a visit to Dr Priestley, and, travelling by slow stages, arrived in Birmingham on Saturday evening. In a letter to a friend he had said, "On the 9th I proceed forward; on the 19th I hope to be at home." On reaching Birmingham he said to a person who called upon him, "You are only come to see the shadow of Robert Robinson." Yet he ventured to preach for the dissenters' charity schools twice on the Sunday. Dr Priestley was charmed with his conversation, but confessed himself much disappointed with his preaching. "His discourse," Dr Priestley said, "was unconnected and desultory, and his manner of treating the Trinity favoured rather of burlesque than of serious reasoning. He attacked orthodoxy more pointedly and sarcastically than I ever did in my life." He had often expressed a wish "to die softly, suddenly, and alone." On Tuesday the 9th of June, the very day on which he had intended to "proceed forward," he was found dead in his bed, neither his clothes discomposed nor his features distorted.

A collected edition of his miscellaneous works, with a memoir by Mr Benjamin Flower, was published in 4 vols. 8vo in 1807, and a volume of posthumous works, by the same editor, in 1812; and his *Village Sermons* were reprinted in 1805 and 1808. For the facts in this article we are chiefly indebted to George Dyer's *Memoirs of the Life and Writings of Robert Robinson*, London, 1796. In Coleridge's *Notes, Theological, Political, and Miscellaneous*, London, 1853, are some remarks on Robinson's *Plea*, and other treatises (p. 112-126). (J. E. R.)

ROBISON, JOHN, a distinguished professor of natural philosophy, born in 1739 at Boghall, in the parish of Baldernock and county of Stirling, was a younger son of John Robison, Esq., who had formerly been a merchant at Glasgow, and had retired to live in considerable affluence on his estate at Boghall, not far from that city. He was of a family sufficiently respectable to enable his son at a subsequent period to prove himself, to the satisfaction of the court of St Petersburg, a gentleman born. As a younger brother, that son was originally intended for the church, and went at an early age, according to the custom of Scotland in 1750, to enter as a student in the university of Glasgow, so that he was initiated almost in the rudiments of Grecian literature under the able instruction of Dr Moor, the well-known professor of Greek; and he acquired such a knowledge of the classical languages as served to constitute him a correct scholar through life. He pursued his studies with so much attention as to obtain the approbation of his teachers and the admiration of his contemporaries, who were delighted with the originality and ingenuity of his conversation, though he did not himself reflect with perfect satisfaction upon the degree of application which he had exerted in his academical education. He took the degree of Master of Arts in 1756, having studied mathematics under Dr Robert Simson, and moral philosophy under Dr Adam Smith. The example of so correct and rigid a follower of the ancient methods of

demonstration as Dr Simson, must unquestionably have exercised considerable influence on his yet unformed taste in mathematics; but he seems to have had a natural preference, either from the constitution of his mind or from some previously acquired habits of thinking, for the geometrical method; for we are informed that "he first attracted the regard of Dr Simson by owning his dislike of algebra, and by returning a neat geometrical solution of a problem which had been given out to the class in an algebraical form; with this mode of solution the professor was delighted, though the pupil candidly acknowledged that it had been adopted only because he could not solve the problem in the manner required of the class." In the course of his studies he had imbibed an insuperable aversion to the pursuit of his original objects in the church; not certainly from any want of religious feeling, or from a dislike to the kind of life that was intended for him, but probably from some difficulties that had occurred to him respecting particular points of doctrine or of practice. He was therefore compelled to provide himself with some other occupation; and he readily accepted the offer of some of his friends in 1758, to recommend him to Dr Blair, a prebendary of Westminster, who had formed a scheme for sending Prince Edward, the young Duke of York, to complete his professional education at sea, in company with a son of Admiral Knowles; and Robison was to have instructed his royal highness in mathematics and navigation. On his arrival in London, he was much disappointed to find that the expedition had never been seriously intended; and he readily accepted an engagement to attend young Knowles as a private tutor, when he went as a midshipman on board of the *Neptune* of ninety guns, with Admiral Saunders, who had the command of a force intended to co-operate with General Wolfe in the reduction of Quebec; and upon the appointment of his friend as a lieutenant on board of the *Royal William*, Robison was himself rated as a midshipman in that ship.

The fleet arrived on the coast of America in April 1759; in May they got up the river, and Robison was one of a party of 100 seamen draughted from the *Royal William* into the admiral's ship, under the command of Lieutenant Knowles. In this capacity he had an opportunity of seeing considerable service, and of making some surveys of the river and of the neighbouring country; an employment for which he was perfectly qualified, both as a geometrician and a draughtsman. He also remarked the effect of the aurora borealis on the compass, which had been noticed by Marian and Wargentim some years before, but which was then not commonly known. After the battle which was signalized by the victory and death of the gallant Wolfe, the *Royal William* sailed with his body to Europe, and arrived at Spithead in November. The next year she was sent to cruise off Cape Finisterre; but in six months she was obliged to return home, from having the greater part of the men disabled by the scurvy. He used to consider the two years that he spent on board of the *Royal William* as the happiest of his life; and no inconsiderable part of his gratification was derived from the study of seamanship as he saw it practised under the auspices of Captain Hugh Pigot. He did not, however, acquire any firm attachment to the mode of life which he had temporarily adopted; he was rather disposed to resume his academical pursuits, and he had overcome his earlier objections to the ecclesiastical profession. He could not, however, refuse the kindly invitation of Admiral Knowles to come and live with him in the country, and to assist him in some important experiments which he was making upon mechanical and nautical subjects. In the month of February 1762 Lieutenant Knowles was appointed to the *Peregrine* sloop of twenty guns, and Robison accompanied him with the hope of be-

Robison.

Robison. coming a purser. He visited Lisbon and several other parts of Portugal; but he found a cruise in a small ship much less convenient and agreeable than in a large one; and, fortunately for himself and for mankind, he finally quitted the *Peregrine* and the naval service in June, and returned to live with Admiral Knowles, who soon after recommended him as a proper person to take charge of Harrison's time-keeper, which had been completed by the labour of thirty-five years, after many unsuccessful experiments, and which was now sent out by desire of the Board of Longitude to the West Indies, under the care of young Harrison and of Robison. The rate of the chronometer was ascertained at Portsmouth the 6th of November 1762, and it indicated at Port Royal, in Jamaica, a difference of time amounting to $5^h 2^m 47^s$, which is only four seconds less than the true longitude. After a few days, the observers had a prompt opportunity of returning home by the *Merlin* sloop, which was sent to Europe with dispatches. The voyage was most disastrous with respect to wind and weather, and at last the ship took fire; but she arrived safe at Portsmouth in March, and on the 2d of April the watch gave $11^h 58^m 61\frac{1}{2}^s$, instead of 12^h , for the time of mean noon; so that the error, after six months, was only $1^m 53\frac{1}{2}^s$, amounting to no more than about 20 miles of distance. Robison received, upon his return, the afflicting intelligence of the total loss of the *Peregrine*, which had foundered at sea, with her commander and the whole of the ship's company. He was also greatly disappointed in the failure of some hopes which had been held out to him from the Admiralty and the Board of Longitude; though in fact there is little reason for the public to regret that he was not gratified with the purser-ship which he claimed as the reward of his services. He was indeed afterwards actually made a purser by Lord Sandwich, in 1763; but he then declined accepting the appointment. His biographers very naturally complain of the neglect of those boards which ought to have recompensed him; but certainly the Board of Longitude had no power whatever, and probably not much influence, in the appointment of a purser; and, after all, the delay of a year or two was nothing very uncommon in the navy.

He had now no other resource than to return to Glasgow, and to resume his academical pursuits with renewed energy. It was from this time that he dated his serious application to his studies. He became extremely intimate with Dr Reid and Dr Alexander Wilson; and he had the advantage of being a witness of two of the greatest steps in the improvement of physical science that have been made in modern times, Dr Black's experimental theory of heat, and Watt's invention of a new steam-engine. Dr Black was the first that determined the quantity of heat required for the conversion of ice into water: Watt, who was settled as a mathematical instrument-maker at Glasgow, had been employed in repairing a working model of Newcomen's engine for one of the professors of the university; and it was the difficulty of supplying this model with steam that suggested to Watt the eligibility of having a separate condenser, and that led him, in conjunction with Dr Black, to a knowledge of the quantity of heat consumed in evaporation. Amid the enthusiasm which is always inspired by the progress of scientific discovery and of practical improvement, Robison found every encouragement and every facility for the pursuit of his favourite objects. He was recommended by Dr Black, upon his removal to Edinburgh in 1766, as his successor in the lectureship of chemistry, though without the appointment of a professor. He took charge also of the education of Mr Macdowall of Garthland, and of Mr Charles Knowles, afterwards Sir Charles. Admiral Knowles was soon after recommended by the British government to the Empress of Russia, in order to effect a reformation in her navy, having been employed on

a similar service in Portugal almost fifty years before: he had always been a firm friend to Robison, and now engaged him on this mission, with a salary of L.250 a year; and they proceeded together to St Petersburg in December 1770. Being hospitably entertained on their way by the Prince-Bishop of Liege, whom they found to constitute, with his chapter and all his servants, a lodge of freemasons, Robison was easily persuaded to become one of that fraternity: in a few days he was made an apprentice, and by degrees obtained the rank of Scottish master, as he has himself related in his publication upon the subject. He continued nearly two years at St Petersburg, still acting in the capacity of private secretary to Sir Charles, who was appointed president of the Board of Admiralty, much to the advantage of the Russian navy, though his improvements were frequently retarded by the prejudices of the native officers. Robison was then appointed inspector-general of the corps of marine cadets at Cronstadt, with a double salary, and with the rank of lieutenant-colonel. His duty was to receive the report of about forty teachers and professors respecting the studies of 400 young noblemen who were their pupils, and to class them according to his judgment of their merits; but he had himself nothing to teach, nor could he have had much occasion for "lecturing fluently in the Russian language," though he was introduced by his friend Kutusoff to the Grand Duke Paul as a proficient in that language; but to the empress he was not personally known. At Petersburg he could have lived without regretting his country in the society of such men as Euler and Alpinus, admired by the Russians, and beloved by the British; but Cronstadt in winter was deplorably melancholy; and in 1773 he was induced, without much difficulty, to make some little pecuniary sacrifice in accepting the professorship of natural philosophy at Edinburgh, which had become vacant by the death of Dr Russell, and to which he had been recommended by Dr Robertson, then principal of the university. His determination was not disapproved by the Russian government, who granted him a pension of about L.80 a year for life; but it was only paid as long as three or four young men, who had accompanied him as pupils, continued to reside at Edinburgh; some discontent having been expressed because he did not keep up a correspondence with the academy on the improvement of maritime education.

He arrived at Edinburgh in September 1774. He married soon afterwards, and continued to reside in that city for the remaining thirty years of his life; paying only an annual visit to his native place, where he possessed a part of the paternal estate; not being solicitous to extend it, although "he did not diminish it otherwise than as it had been diminished before," that is, in making provision for younger children. His predecessor had been very judicious and successful as a lecturer, though not a mathematician of the highest order: he had himself more practical knowledge and experience in mechanics, and was better acquainted with the foreign mathematicians, who had naturally fallen under his notice during his residence on the Continent. His lectures were considered by most of his pupils as somewhat too difficult to be followed; a complaint which, if it did not depend on their own want of preparatory information, arose perhaps rather more from the hasty manner of his delivery, than from the abstruseness of his matter. "The singular facility of his own apprehension," says Professor Playfair, "made him judge too favourably of the same power in others. To understand his lectures completely was, on account of the rapidity and the uniform flow of his discourse, not a very easy task, even for men tolerably familiar with the subject. On this account, his lectures were less popular than might have been expected from such a combination of talents as the author of them possessed." This inconvenience was increased

Robison.

Robison. "by the small number of experiments he introduced, and a view that he took of natural philosophy, which left but a very subordinate place for them to occupy. An experiment, he would very truly observe, does not establish a general proposition, and never can do more than prove a particular fact;" but he seems to have carried this principle to some little excess; it is, in fact, the *illustration*, and not the *proof*, of general principles that is the object of a public exhibition of experiments; and it is very doubtful whether Archimedes, or Newton, or Leibnitz, or Euler, would have been very successful as *showmen*. With respect, however, to "accuracy of definition, to clearness, brevity, and elegance of demonstration, and even to neatness and precision in experiments," Professor Robison was very successful; his course extended "to every branch of physics and of mixed mathematics," and entered so fully into the detail of each particular division of the subjects, that "a more perfect system of academical instruction is not easily to be imagined." Nothing, in short, was wanting, but so much previous knowledge of mathematics in his pupils as he thought he had a right to expect, though his expectations were too rarely fulfilled. The Philosophical Society of Edinburgh had almost been suffered to sink into oblivion after the publication of the third volume of its Essays, in 1756. Professor Robison became a member of it soon after his return from Russia, and was chosen secretary of the new society upon its formation by royal charter in 1783, when it incorporated with itself the whole of the surviving members of the former society. In 1798 he received the compliment of a degree of Doctor of Laws from the university of New Jersey; and a similar honour was paid him at Glasgow the year after. In 1800 he was elected, as successor to Dr Black, on the list of the foreign members of the Royal Academy of Sciences of St Petersburg.

In 1785 he was attacked by a severe disorder, from which he was never afterwards wholly free, though it produced little inconvenience besides pain, with some depression of spirits, which was, however, attributed rather to the closeness of his application than to the immediate effect of the disease, which was a glandular induration. For many years he was obliged to obtain the assistance of substitutes in the delivery of his lectures; but towards the end of his life he was able again to perform the duties of the professorship in person. He continued his literary labours with little intermission, and was most happy in the care and attention of his wife and children, whose virtues he found the best alleviation of his sufferings. He took a slight cold, after giving a lecture, on the 28th of January 1805, and died on the 30th.

1. It was comparatively late in life that Professor Robison assumed the character of an author, having communicated to the Royal Society of Edinburgh, in 1786, a paper on the Determination of the Orbit and Motion of the Georgium Sidus, which was published in the *Edinburgh Transactions*, vol. i. He had observed the opposition of the planet with an equatorial telescope only, and he had computed the elements of its orbit with greater accuracy than any other astronomer had then done; although his suspicion of the effect of such a planet on the motions of Jupiter and Saturn has not been confirmed by later investigations, the irregularities of these planets, on the contrary, having been otherwise explained.

2. A second paper, published in the same collection, vol. ii., p. 82, relates to the Motion of Light, as affected by refracting or reflecting substances which are themselves in motion. The author corrects some errors of Boscovich, who had miscalculated the effect of a water-telescope; but he seems to agree with Dr Wilson in the suggestion of another experiment of a similar nature, which, to say the least, is wholly superfluous.

3. The most important, beyond all comparison, of Professor Robison's scientific publications, are the articles which he communicated from time to time to the third edition of the *Encyclopædia Britannica*, and to its Supplement. It was under the care of Mr

Colin Macfarquhar that the first twelve volumes of the third edition of this work were published; and upon his death, in 1793, the task of continuing it was committed to Dr Gleig, to whom Professor Robison became a most essential co-operator, and from that time "the work ceased to be a mere compilation." The first of his contributions, according to Professor Playfair, was the article OPTICS, but it is probable he only revised and enlarged that article: it was followed by PHILOSOPHY,¹ which he wrote jointly with Dr Gleig; by PHYSICS, PNEUMATICS, PRECESSION, PROJECTILES, PUMPS, RESISTANCE, RIVERS, ROOF, ROPE-MAKING, ROTATION, SEAMANSHIP, SIGNAL, SOUND, SPECIFIC GRAVITY, STATICS, STEAM, STEAM-ENGINE, STEELYARD, STRENGTH, TELESCOPE, TIDE, TRUMPET, VARIATION, and WATER-WORKS; and in the Supplement, by ARCH, ASTRONOMY, BOSCOVICH, CARPENTRY, CENTRE, DYNAMICS, ELECTRICITY, IMPULSION, INVOLUTION, MACHINERY, MAGNETISM, MECHANICS, PERCUSSION, PIANOFORTE, POSITION, TEMPERAMENT, THUNDER, TRUMPET, TSCHIRNHAUS, and WATCH-WORK. Notwithstanding some degree of prolixity and want of arrangement, which could scarcely be avoided, in the preparation of original articles for such a mode of publication, the whole of them, taken together, undeniably exhibit a more complete view of the modern improvements of physical science than had ever before been in the possession of the British public; and display such a combination of acquired knowledge with original power of reasoning as has fallen to the lot of a few only of the most favoured of mankind.

4. It is not altogether with so high approbation that his friends and his biographers have mentioned a work, of a nature rather political than philosophical, entitled *Proofs of a Conspiracy against all the Religions and Governments of Europe* (Edin. 1797, 8vo), though it went through several editions. The principal part of the book consists of the history of the *Illuminati* and the German Union, whom he considers as having become the chief agents in a plot first formed by the freemasons, at the suggestion of some Jesuit, who proposed for their model the internal economy of the order which he had quitted; and whatever foundation this outline may have had in truth, there is no doubt that the manner in which Professor Robison has filled it up betrays a degree of credulity extremely remarkable in a person used to calm reasoning and philosophical demonstration: for example, in the admission of a story told by an anonymous German author, that the minister Turgot was the protector of a society that met at Baron d'Holbach's, for the purpose of examining the brains of *living children*, in order to discover the principle of vitality. He does not accuse the English freemasons of having participated in the conspiracy; but he considers the continental lodges as having been universally implicated in it.

5. After the death of Dr Black, in 1799, he undertook to superintend the publication of his *Lectures on Chemistry*, which appeared in 1803, 2 vols. 4to. And this task, which was rather laborious than difficult, he executed with equal zeal and ability. He endeavoured to reduce to their just estimate the comparative pretensions of the French and British chemists, though he is somewhat puritanically severe in criticising the literal meaning of the compliments paid to Black by Lavoisier, on which he founds a charge of insincerity.

6. His last publication was the first volume of a series which was to form a complete system, entitled *Elements of Mechanical Philosophy*, Edin. 1804, 8vo. It comprehended only Dynamics and Astronomy, and it never became very popular. It was too difficult for the many, who wished for general and philosophical notions only, and not sufficiently precise and demonstrative for the few, who wanted practical and numerical results. In attempting to combine the separate merits of the *Exposition du Système du Monde* and of the *Mécanique Céleste*, the author sacrificed both the popular simplicity of the former and the mathematical perfection of the latter. A few inaccuracies, which ought not to escape the attention of the reader of the work, were pointed out in the *Imperial Review* for March 1805, a journal long since discontinued.

7. The contents of the volume last mentioned, together with some manuscripts intended to have formed part of a second, and the greater part of the articles furnished by Professor Robison to the *Encyclopædia*, were collected into a *System of Mechanical Philosophy*, with Notes, by David Brewster, LL.D. (now Sir David Brewster), Edin. 1822, 4 vols. 8vo,—a spirited bookseller in London having undertaken the risk of the publication.

"Although Dr Robison's name," says Dr (now Sir David) Brewster in his preface, "cannot be associated with the great discoveries of the century which he adorned, yet the memory of his talents and his virtues will be long cherished by his country. Im-

¹ It is scarcely necessary to observe that, in the present edition (the eighth), a considerable number of those articles have been rewritten, owing mainly to the advanced state of the several sciences since Professor Robison's day.—*Ed.*

Robson.

bued with the genuine spirit of the philosophy which he taught, he was one of the warmest patrons of genius wherever it was found. His mind was nobly elevated above the mean jealousies of rival ambition, and his love of science and of justice was too ardent to allow him either to depreciate the labours of others, or to transfer them to himself. To these great qualities as a philosopher Dr Robison added all the more estimable endowments of domestic and of social life. His friendship was at all times generous and sincere. His piety was ardent and unostentatious. His patriotism was of the most pure and exalted character; and like the immortal Newton, whose memory he cherished with a peculiar reverence, he was pre-eminently entitled to the high distinction of a Christian, patriot, and philosopher." His person was handsome and his physiognomy prepossessing; and he appears to have been endowed with an extraordinary combination of talents, even exclusively of those which were called into immediate activity in his professional pursuits, for he was a good linguist, an excellent draughtsman, and an accomplished musician. His conversation was always energetic and interesting, and sometimes even poetical; and his liberality of sentiment was only limited by his regard for what he considered as the best interests of mankind.

A short account of his life was published in 1802 by a contributor to the *Philosophical Magazine*, who, among other inaccuracies, asserted that Robison was an admirer of the algebraical form of representation in preference to the, geometrical. His friend Dr Gleig soon after stepped forward to correct these mistakes, in the *Anti-Jacobin Review* for 1802, and his letter was copied into the *Philosophical Magazine*. He asserts, from his own knowledge, that even yet Professor Robison "delights much more in geometry than in any of the modes of algebra, assigning as the reason of his preference, that in the longest demonstration the geometrician has always clear and adequate ideas, which the most expert algebraist can very seldom have." It may perhaps be asserted, on the other hand, that the same reasoning would lead us always to employ actual multiplication or division in preference to the use of logarithms or of a sliding rule, and that the whole of the magic of calculation depends on the abstraction of the results from the numerous and separately unimportant steps by which they are obtained; but the having once seen those steps clearly is certainly of great importance to the process of reasoning, even when the memory no longer retains them; and no mathematician of correct taste can study the ancient geometers without admiring the elegance and precision of their method, even amidst the pedantry which too frequently envelopes their expressions, and without being grateful for their punctuality in collecting their results into the very convenient form of distinct propositions, and in making such references from each proposition to the foundations on which it depends, as to enable him readily to trace back their steps to the most elementary principles; which is scarcely possible in any of the works of the most modern school of analysis. Professor Robison, however, seems rarely to have cultivated the higher mathematics for their own sake only, or any further than as they could be applied to the study of the phenomena of nature, or to the practice of the combinations of art; in fact, without some such limitation, there would be no track to guide us in the pathless regions of quantity and number, and their endless relations and functions. But besides the utility of the pure mathematics as a branch of early education, in exercising and fortifying the powers of the mind, it is impossible to foresee with certainty *how much* of mathematics may be wanted by the natural philosopher in any given investigation; and Professor Robison, as well as many others of his countrymen, would certainly have been the better for the possession of a little more, as the author of the criticisms in the *Imperial Review* has already had occasion to remark.

(*Philosophical Magazine*, xiii.; Dr Gleig, in *Anti Jacobin Magazine*, xi., 1802; Stark's *Biographia Scotica*; Alkin's *General Biography*, viii., Lond. 1813, 4to; Playfair, in *Edin. Trans.* vii., 1815, p. 495; Chalmers's *Biographical Dictionary*, xxv., Lond. 1816, 8vo.)

(T. Y.)

ROBSON, GEORGE FENNEL, an eminent landscape-painter in water-colours, who was born at Durham in 1790, was a great devotee of his art. From the artists who came to sketch in the neighbourhood of his native town he picked up a knowledge of drawing. With five pounds in his pocket, he then set out to try his fortune in London. There his pencil was plied assiduously, until he had scraped together a sum sufficient to enable him to gratify his long-cherished desire of travelling. Making a tour through the United Kingdom, he explored with enthusiasm the Highlands of Scotland, the mountains in the north of England, and the lakes of Killarney. Every striking piece of

Rochdale.

scenery was lingered over; every aspect of nature was copied; and he returned to London with his sketch-book rich in materials for future use. Robson now began to be very successful in his profession. His pictures, though numerous, readily found purchasers. Some of his works, such as "The View of London from the Bridge," "The City of Durham," and "Outlines of the Grampian Mountains," brought his name into note. He died in 1833, much regretted by the public at large. Robson was the artist of the illustrations in Britton's *English Cities*, and of "Landscape Illustrations of the Waverley Novels." (See Bryan's *Painters and Engravers*.)

ROCHDALE, a parliamentary borough and market-town of England, in the county of Lancaster, in a beautiful valley on the Roch, here crossed by five bridges, 10 miles N.N.E. of Manchester, and 200 N.W. by N. of London. It stands on both sides of the river, and has been recently very much improved. Most of the houses are built of brick, and roofed with stone instead of slate; but some are of freestone quarried in the vicinity. In the principal street, which is broad, and, like most of the others, well paved, stand the market-house and town-hall, the latter a neat edifice, serving also as a news-room. On a height, approached by a flight of 126 steps, stands the parish church, an ancient building in the Norman and early English styles. It has a square embattled tower, several richly-carved windows, an ancient font, and some interesting tombs. The plain brick church of St Mary was built in 1740, and that of St James in 1814. Other places of worship there are, belonging to Roman Catholics; Independents; Baptists; Wesleyan, Association, and Primitive Methodists; Quakers; Unitarians, and others. To most of these Sunday schools, largely attended, are attached. The grammar school of Rochdale, founded in 1564, had only nine pupils in 1854. The school-house has recently been rebuilt in the Elizabethan style. A large national school, two endowed schools, and others, are among the educational establishments of the town. A literary institute, an atheneum, a people's institute, with libraries and reading-rooms, also contribute to the diffusion of knowledge among the inhabitants; and the relief of the poor is provided for by a dispensary, poor-house, and other charitable institutions. It is chiefly, however, for its industrial importance that the town is remarkable. Woollen and cotton goods, especially the former, form the staple of the manufactures. Baize, flannel, friezes, and blankets, are the principal kinds of woollen, and strong calico the most important among the cotton fabrics made here. Hat-making and cotton-yarn spinning furnish employment to a great number of the people. Rochdale has also iron and brass foundries and machine-works. In most of the factories steam-power is employed. Within the bounds of the parish there are coal-pits, iron-mines, and quarries of sandstone, &c. Two markets are held weekly, one for manufactures and other articles, and the other for provisions; and there are fairs three times a year. The trade of the town is facilitated by the Rochdale Canal, which passes at a short distance from it, and unites the Duke of Bridgewater's canal at Manchester with the waters of the Calder and Ribbles near Halifax. It is 33 miles long, and was constructed at a great cost, and opened in 1804. The railway between Manchester and Leeds has a station here. The borough was not represented in Parliament before the Reform Act of 1832, but it now returns one member. It is governed by the magistrates of the county, and has a county court and a convenient jail. Rochdale is a place of much antiquity, as even under the Romans there was a station in the neighbourhood; but the history of the town presents few events of importance. In the reign of Edward III. the woollen manufacture was introduced by some Flemish emigrants; and Rochdale acquired a celebrity for such articles,

Rochefort-
sur-Mer
||
Rochefou-
cauld.

which it retained in the time of Elizabeth. As early as 1610 there were five fulling-mills in the parish. The beautiful manor of Rochdale, near the town, was long the property of the Byron family, but was sold by the poet. Pop. of the borough (1851) 29,195.

ROCHEFORT-SUR-MER, a town of France, capital of an arrondissement in the department of Charente-Inférieure, situated partly on a hill and partly on a marshy plain, on the right bank of the Charente, 9 miles above its mouth, and 20 miles S.E. of La Rochelle. In form it is semicircular, inclosed towards the land by ramparts. It is altogether modern. The streets are broad and regular, many of them planted with rows of trees; and the houses, though low, are in general very handsome. The principal streets meet in the Place d'Armes, a regular square, in the centre, adorned with a fountain and with trees. The most conspicuous edifice is the large naval hospital, on a height outside of the town. Rochefort derives its chief importance from its naval arsenal, which is considered the third of its kind in France. Dockyards, sail-shops, rope-works, biscuit manufactories, storehouses, naval schools, and other establishments connected with maritime affairs, are to be seen here. The harbour is capacious, and deep enough for the largest vessels: it is divided into two parts, for merchantmen and men-of-war respectively. The roadstead is large, and well sheltered by the islands of Ré, Oleron, and Aix. Besides the fortifications of the town, there are five forts to guard the mouth of the river. The town contains a college, courts of law, and a large convict prison. Ship-building is the principal branch of industry here; but there are also sugar and vinegar works. An active trade is carried on in the produce of the adjacent country and colonial goods. Rochefort was made a naval station by Louis XIV. in 1666. It was here that Napoleon, in 1815, gave himself up to Captain Maitland of the Bellerophon, after a vain attempt to escape to America. Pop. (1856) 21,372.

ROCHEFOUCAULD, FRANÇOIS, *Duc de la*, Prince of Marsillac, governor of Poitou, was born in 1613. He was the son of Francis, the first Duke of Rochefoucauld, and was distinguished equally by his courage and his wit. These shining qualities endeared him to all the nobility at court, who were ambitious of decorating themselves at once with the laurels of Mars and of Apollo. He wrote two excellent works: the one a book of *Maxims*, which Voltaire says has contributed more than anything else to form the taste of the French nation; and the other, *Memoires de la Regence d'Anne d'Autriche*. It was partly at the instigation of the beautiful Duchess de Longueville, to whom he had long been attached, that the Duc de Rochefoucauld engaged in the civil war, in which he signalized himself, particularly at the battle of St Antoine. After the civil wars were ended, he thought of nothing but enjoying the calm pleasure of friendship and literature. His house became the rendezvous of every person of genius in Paris and Versailles. Racine, Boileau, Saligné, and Lafayette found in his conversation charms which they sought for in vain elsewhere. He was not, however, with all his elegance and genius, a member of the French Academy. The necessity of making a public speech on the day of his reception was the only cause that he did not claim admittance. This nobleman, with all the courage he had displayed upon various critical occasions, and with his superiority of birth and understanding over the common run of men, did not think himself capable of facing an audience to utter only four lines in public, without being out of countenance. He died at Paris in 1680, aged sixty-eight, leaving behind him a character which has been variously drawn by those who during his life were proud of his friendship.

Rochefoucauld's *Memoirs of the Regency of Queen Anne of Austria* are written with much elegance and spirit, displaying a faithful picture of that stormy time, in which the

Rochester.

painter was himself one of the leading actors. In his *Reflections and Maxims* he lays it down as an absolute rule, that all the actions of men are under the guidance of self-love or of self-interest. This self-love, vanity, or pride, he maintains to be the poison with which universal humanity is tainted, and which it is impossible for man to remove by all the efforts of his reason. Such being Rochefoucauld's view of human nature, it need not be wondered at that the tone of his book does not rise, in any case, beyond the grovelling speculation with which he sets out. This theory perpetually clings to it; and despite its very great claims upon our attention as a book written with singular elegance, it will be more or less regarded by all thinking men more as a satire upon human nature, than as a book calculated to make men better. A very good and very perfect edition of the *Maxims* is that of Gabriel Brotier, Paris, 1789; there is likewise a more recent one by Aimé Martin, 1822. The *Œuvres* of Rochefoucauld were published in 1818, with a notice of his life and works by Depping; and another edition in 1825, with a biographical and literary notice by his relation the Count Gaetan de la Rochefoucauld. The *Maxims* have been frequently translated into English.

ROCHELLE, LA, a town of France, capital of the department of Charente-Inférieure, on the north shore of an inlet of the sea, 295 miles W. by N. of Paris. It is encircled by fortifications, and entered by seven gates. Its broad, straight streets are lined with buildings, which, though not lofty, are generally good. The most of the town is built round the harbour, which is bordered with an elegant quay shaded by rows of trees. The town-hall is a fine building in the *renaissance* style of the time of Francis I.; the cathedral, exchange, court-house, and public library are among the ornaments of the town. Many of the squares and public walks are exceedingly beautiful. La Rochelle contains several schools, hospitals, a botanic garden, mint, arsenals, &c. The manufactories of the place include potteries, glass-works, ship-building yards, sugar refineries, and cotton factories. The harbour is very safe, and admits vessels of 400 or 500 tons. An extensive trade is carried on in wine, brandy, oil, salt, timber, iron, colonial produce, &c. The town of Rochelle is ancient; but no remarkable event is connected with its history till the time of the Reformation. Before 1372, it had been alternately possessed by the French and English; but was finally secured for the former in that year by Du Guesclin. In 1557 the Huguenots obtained possession of La Rochelle, and retained it for seventy-two years, defending themselves against a siege in 1572, and only surrendering on honourable terms in 1629, after a blockade of fourteen months. The mole constructed by Richelieu to close up the harbour on that occasion may still be seen at low water. Pop. (1856) 14,157.

ROCHESTER, a market-town and municipal and parliamentary borough of England, in the county of Kent, on the right bank of the Medway, 8 miles N. of Maidstone, and 29 E.S.E. of London. It forms almost a continuous town with Chatham and Brompton on the E., and Stroud, across the river, on the W. The streets are generally irregular; the principal one, forming part of the London and Dover road, extends from Chatham to the bridge over the Medway, at the W. end of the town, a length of more than 2 miles. The most of the houses are ancient in appearance; many of them are built of wood, with the gables turned to the street. In the outskirts, however, and along the banks of the river, stand many fine new houses and neat villas. The principal building is the cathedral, built by Bishop Gundulph in the eleventh century, on the site of a more ancient edifice, said to have been founded in 604. It has a nave and aisles; a choir, raised above the level of the nave; two transepts, the larger at the junction of the nave and choir, and the smaller at the east end of the latter. Its dimensions are as follows:—Length of the nave, 150 feet; breadth, with

2 H

Rochester. aisles, 66 feet; length of the choir, 156 feet; total length of the church, 306 feet; of the larger transept, 122 feet; of the smaller, 90 feet. A tower, built in 1825, rises from the centre; one, now in ruins, called Gundulph's Tower, from the north side of the choir, near the principal transept; and two others dissimilar in appearance, flank the doorway at the west end. This front was formerly adorned with other two towers at its extremities. The style of the building is partly Norman and partly early English; on the exterior it does not present a very imposing aspect, but the interior has been recently repaired with great taste. The monuments that it contains are more distinguished for singularity than for beauty. Underneath, in a large crypt, the ruined chapter-house has been replaced by a mean building serving the purpose of the former, and also containing a library. Rochester has two parish churches, one in the perpendicular, and another in a mixed style. There are also places of worship for Wesleyans, Independents, Quakers, and Jews. At the south-east of the town the ancient castle towers above the waters of the Medway. It has long been in a state of decay; the outer walls, which inclosed a large area, are in ruins, but the strong massive keep still rises in the centre to the height of 104 feet, with turrets 12 feet higher at each corner. This is considered one of the best extant specimens of Norman military architecture. Another fine building in Rochester is the brick town-hall, with its Doric portico in front. There is also a jail, theatre, assembly-rooms, &c. The cathedral grammar school, founded in 1542, has four exhibitions at Oxford and Cambridge, and contained 62 scholars in 1854. A free mathematical school, with 47 scholars in the same year; national and British schools, also provide for the education of the people. The charitable institutions include a dispensary, alms-houses, and a charity for poor travellers. Rochester has no manufactures, if we except a small amount of ship-building; but many of the inhabitants are employed in the dockyards and other establishments at Chatham. Oyster fishing is carried on; and there is some trade, chiefly in coal, by means of coasting vessels. The number of sailing-vessels registered at the port, December 31, 1857, was 415, tonnage 19,086; of steamers, number 5, tonnage 228. The number of sailing-vessels that entered in that year was 213, tonnage 27,748; of steamers, number 117, tonnage, 18,544; of those that cleared 70 sailing-vessels, tonnage 6411, and 29 steamers, tonnage 3650. The stone bridge of eleven arches over the Medway was built in the reign of Richard II. Farther down, the river is crossed by a new iron bridge of three lofty arches, the central one opening in the middle to allow the passage of large vessels. Two weekly markets, a monthly cattle market, and two yearly fairs are held at Rochester. Quarter-sessions and a county court meet here. The borough is governed by a mayor, 5 other aldermen, and 18 councillors; and represented in Parliament by 2 members. The existence of Rochester can be traced back with probability to the period before the invasion of the Romans, by whom it was called *Durobriva*. Under the Saxon kingdom of Kent it was important as a stronghold, and the seat of a bishop. In 676 it was destroyed by the Saxons of Mercia; again in 839 by the Danes, into whose hands it had almost fallen a second time in 885, had it not been rescued by Alfred. The town and castle were strengthened by William the Conqueror; and afterwards sustained several attacks, one of which was from the rebels under Wat Tyler. In 1667 the Dutch made a descent on Rochester; and in 1688 James II. took ship to France from this port. Pop. (1851) 14,938.

ROCHESTER, a town of the United States of North America, in the state of New York, on both sides of the Genesee, 7 miles above its mouth, in Lake Ontario, and 230 W. by N. of Albany. It is built on level ground, with broad, straight, well-paved streets, the principal of which

run from E. to W. through the middle of the town. The houses are for the most part built of limestone or brick; many of them are surrounded with gardens; and the streets are generally lined with rows of trees. The court-house and city-hall, a large and handsome edifice, with a granite front; the arcade, a fine building partly occupied by the post-office; the western house of refuge for juvenile delinquents, a large brick structure; the university buildings, as well as many handsome churches of different sects, form the most conspicuous ornaments of the town. The university of Rochester, founded in 1850, is under the direction of the Baptists, and had in 1857, 8 professors, 165 students, and a library of 5200 volumes. There is also a Baptist theological seminary, containing in 1856-7, 3 professors and 36 students. The town has numerous schools, an atheneum, two orphan hospitals, and other benevolent institutions. Several newspapers and other periodicals are published. The prosperity of the place must chiefly be ascribed to the great amount of water-power within reach; for the Genesee descends within a short distance by three cataracts and two rapids, in all 373 feet; and the inhabitants have not been slow to make use of these advantages. The chief establishments are flour-mills, which are perhaps the most extensive in the United States, and produced in 1852, 538,680 barrels of flour. Machinery, cutlery, iron, leather, cloth, paper, and other articles are also made here. The town is remarkable for the extent of its fruit nurseries. The Erie Canal, which traverses the centre of the town, and crosses the river on an aqueduct of stone, extends westward to the lake of the same name; and the Genesee Valley Canal opens up communication with the south. The steam-boat navigation, which extends on the river to within 2 miles of the town, and the several railways which diverge from it, increase the facilities for commerce that Rochester possesses. The shipping of the district, June 30, 1852, had an aggregate tonnage of 686 enrolled and licensed, of which 429 tons belonged to steamers. During the year ending on that day there entered (exclusive of canal navigation) 264 vessels, with a tonnage of 38,903; and there cleared 200, tonnage 33,027. Rochester was first settled in 1812, and received its charter in 1834. Pop. (1850) 36,403; (1853) about 42,000.

ROCKET. See **PYROTECHNY**.

ROCKY MOUNTAINS, called also, but not so generally, *Chippewayan Mountains*, the principal range in North America, extending from the shore of the Arctic Ocean, near Mackenzie Bay, about 70. N. Lat., in a S.E. direction, through the continent. The name is sometimes applied to the whole range of mountains so far S. as 19. N. Lat., where they are interrupted by the low lands in Nicaragua and the isthmus of Panama: but, properly speaking, the Cordilleras of Mexico do not form part of the Rocky Mountains, nor are they indeed immediately connected with that chain. In its stricter application, the term designates only the mountains which traverse the British possessions and the United States, and terminate a few miles S.E. of Santa Fe in the territory of New Mexico. They form a part of the great mountain chain, which, with a few interruptions and under various names, traverses the whole of the Western Continent from very nearly its extreme northern to its extreme southern point, forming the watershed between the Atlantic and Pacific oceans, though much nearer the latter than the former. The northern range, however, does not approach so near to the sea as the southern range does at almost all parts of its course. Near the southern extremity of the Rocky Mountains, and not far from the source of the Arkansas River, is a knot of mountains from which various chains diverge in different directions,—the Sierra de San Juan, stretching S.W. towards the Sierra Madre; the Rocky Mountains, on the one hand N.W., and on the other S.E.; and the

Rocket
||
Rocky
Mountains

Rocroy. Medicine Bow Hills towards the N.E. The main ridge continues in a single almost unbroken line as far northwards as Mount Brown, about 53. N. Lat., where a lower ridge diverges and runs nearly parallel to the principal chain, a short distance to the W. This second chain is known by the name of the Peak Mountains, and sends off another range, also parallel to the two former, and still nearer the coast. The loftiest summits of the Rocky Mountains throughout the greater part of their length rise from 10,000 to 14,000 feet; but N. of Mount Brown, where the divergence takes place, they begin to diminish in altitude, and towards the extremity their average height is not more than 2000 feet. The highest elevation in the southern part of the range is Fremont's Peak, 13,570 feet above the sea. Farther N., between Lat. 46. and 48., there is a considerable depression; but beyond this there is another elevated portion, where Mount Hooper (15,690 feet) and Mount Brown (about 16,000 feet) rise. Some peaks are said to attain the height of 18,000 feet above the sea. The mountains are traversed by several passes. Among these are South Pass, immediately south of Fremont's Peak, forming the principal route to the Mormonite settlements in the W.; Lewis and Clarke's Pass, near the head waters of the Missouri, 6323 feet high; and Athabasca Portage, between Mounts Hooper and Brown, about 7300 feet. The two former of these have been proposed as railway routes across the North American continent. Very recently several additional passes have been discovered by Captain Palliser, some account of which will be found in the *Proceedings of the Royal Geographical Society* for Feb. 1859.

As the range has been but imperfectly explored, little is known of its geological character. There seems, however, no reason to doubt that its structure is primitive. The upper portions consist of granite and gneiss, rising up in bare, rugged, and precipitous peaks. This formation is overlaid in the higher slopes with limestone, and in the lower with sandstone. Volcanic rocks exist in some places; and there is said to be a volcanic region, 100 miles in length, near Fremont's Peak, containing several burning mountains now in activity. Hot springs are found not only here, but in several other places on both slopes of the range; one of the most remarkable being that called the Steamboat Spring, sending up the water to the height of 3 feet. The eastern declivity of the mountains is in general much more precipitous than the western, which in some places rises to a series of terraces and inferior ridges. Many of the summits are covered with perpetual snow. They are seen like a vast rampart rising from the grassy plains, stretching from north to south. Sometimes their aspect is that of continued ranges of a grayish colour, rising into the blue of the atmosphere above the region of the clouds. A great number are black, ragged, and precipitous; and their bases are strewn with immense boulders and fragments of rock, detached by earthquakes and the elements. From this iron-bound and precipitous character they probably received the appellation of Rocky Mountains. They are for the most part but thinly covered with vegetation, a few scrub pines and other trees being all that clothes the lower slopes; but in some places there are magnificent forests. The rivers that take their rise in the Rocky Mountains fall into three great divisions: those which flow into the Arctic Ocean or Hudson's Bay, of which the Athabasca and the Saskatchewan are the chief; those which flow into the Gulf of Mexico, of which the Missouri is the largest; and those which join the Pacific or the Gulf of California, especially the Columbia and Colorado.

ROCROY, a frontier town of France, capital of an arrondissement in the department of Ardennes, in a beautiful plain in the midst of the forest of Ardennes, 15 miles N.N.W. of Mézières. It is strongly fortified, and contains a foundry for cannon-balls and other projectiles. In the

neighbourhood of the town Condé gained a great victory over the Spaniards in 1643. Pop. (1856) 2686.

RODEZ, a town of France, capital of the department of Aveyron, on a hill washed on three sides by a curve of the Aveyron, which flows 150 feet below, 312 miles S. of Paris. Owing to the nature of the site, most of the streets in the town are steep, and their narrowness is increased by the projecting fronts of the houses, which are for the most part meanly built of wood. The fortifications that once inclosed the place are now turned into public walks, commanding a wide prospect over a somewhat bleak country. The most conspicuous building is the cathedral, whose erection was spread over two centuries, from the end of the thirteenth. Its richly-carved belfry rises to the height of 265 feet; and many of its internal ornaments are very fine. Rodez has also an episcopal palace, town-hall, prefect's office, Jesuits' college, public library, Cordeliers' monastery, and an hospital; manufactures of leather, serge, candles, hats, and playing-cards are carried on; and there are also dye-works and worsted-mills in the town. The trade is considerable in manufactured articles, wool from the neighbouring country, and cheese. Rodez contains a court of law, chamber of manufactures, schools, scientific societies, museum, &c. Pop. (1856) 8479.

RODNEY, **GEORGE BRYDGES**, *Baron* of Stoke, was born on the 19th of February 1718. He was the descendant of an ancient family, and was related to the Duke of Chandos. He bore the name of his Majesty, who stood sponsor for him at his baptism. At a very early age he was sent to Harrow school; and having quitted it at the age of twelve, he received from the king a letter of service, the last ever granted, and went to sea. On the Newfoundland station he served for six years with Admiral Medley. On the 15th of February 1739 he was made lieutenant in the Dolphin, by Admiral Haddock, in the Mediterranean, and served successively in the Essex, Royal Sovereign, and Namur. Admiral Mathews having in 1742 appointed him to the Plymouth, of sixty-four guns, he convoyed 300 sail of the Lisbon trade through the midst of the French fleet, then cruising in the channel; and for his conduct on this occasion he received the warmest thanks of the merchants. In the rank of captain he was confirmed by the Admiralty, and was appointed to the command of the Sheerness, in which he continued for eighteen months. He was then removed to the Ludlow Castle, of forty guns. In this ship he fought and took the great St Maloes privateer, of forty guns, and one hundred men above his own complement. From this period till December 1745 he was employed in various pieces of service, which afforded him no particular opportunities of obtaining distinction. Having been appointed to the Centurion, he for two years cruised in the North Sea. He was now promoted to the command of the Eagle, of sixty-four guns; and in 1747 he was despatched in a small squadron for the purpose of intercepting the French fleet, homeward-bound from St Domingo. On the 20th of June they fell in with this fleet off Cape Ortegal. The French men-of-war deserted their convoy during the night, and no fewer than forty-eight merchantmen were captured. Rodney afterwards joined the squadron of Admiral Hawke, and bore a distinguished part in the action off Finisterre on the 14th of October in the same year. Near the close of this war a small squadron, of which the Eagle was one, fell in with a Spanish fleet from the West Indies, consisting of twelve sail of the line, with a rich convoy, and notwithstanding their own inferiority, they took from them six sail of merchantmen.

Captain Rodney was appointed to the Rainbow in March 1748, and was soon afterwards sent as governor and commander-in-chief on the Newfoundland station. This was his first appearance with the rank of commodore. He had received particular instructions to discover, if possible, an

Rodez
Rodney.

Rodney.

island in the Western Ocean, said to be in Lat. 49. N., about 300 leagues from Britain. After cruising fourteen days to no purpose, he sailed for St John's, the seat of his government. In this station he continued till the month of October 1752, when he returned home to take his seat in Parliament, having been elected for the borough of Sal-tash. In May 1577 he sailed in the Dublin, of seventy-four guns, with Hawke's expedition for the bombardment of Rochefort; and in February 1758, with Boscawen in the expedition against Louisbourg. On the 19th of May 1759 he was promoted to the rank of rear-admiral, and was immediately appointed to the command of a small squadron destined to bombard Havre de Grace. This service he performed in a very effectual manner; and having continued to keep the sea till the close of the ensuing year, he returned to Britain. In 1761 he was elected member of Parliament for Penryn. On the 6th of October he hoisted his flag on board the Marlborough, having been appointed commander-in-chief at Barbadoes and the Leeward Islands, and to conduct the naval operations of the armament destined for the attack of Martinique. This island, together with St Lucia, was speedily reduced.

The admiral returned home on the 12th of August 1763, On the 21st of the preceding October he had been made vice-admiral of the blue. In 1764 he was created a baronet, and during the following year was appointed governor of Greenwich Hospital. In 1768 he was returned to Parliament for Northampton. On the 18th of October 1770 he became vice-admiral of the white, and on the 24th of October 1771 vice-admiral of the red. During the latter year, on the 23d of January, he had been appointed commander-in-chief at Jamaica, and with this command was not permitted to retain the office of governor. Having returned to Britain, he struck his flag at Portsmouth on the 4th of September 1774. Being inattentive, as many seamen are, to the rules of economy, his circumstances became so embarrassed that he was obliged to fly from his country, with very slight hopes of ever being able to return. He was in France when the ill-advised policy of that court prompted them to take a decided part with America against Great Britain; and it is said that some men in power, no strangers to the desperate state of Sir George's affairs, offered him a high command in the French navy if he would carry arms against his own country. This offer he rejected with becoming indignation. Soon after this gallant behaviour the Duc de Chartres, afterwards Duke of Orleans, told Sir George that he was himself to have a command in the fleet to be opposed to that under the command of his countryman Keppel; and with an insulting air asked him what he thought would be the consequence of their meeting. "That my countryman will carry your highness with him to learn English," was the high-spirited reply. These statements do not perhaps rest on sufficient authority; but we learn from his own correspondence that Maréchal Biron expressed his willingness to advance whatever sum he might require, even to the amount of L.2000. Having accepted a loan of a thousand louis, he was in 1778 enabled to pay his bills in Paris, and to revisit his own country. He was speedily enabled to discharge this debt, and to make a satisfactory arrangement with his creditors.

On the 1st of October 1779 Rodney was appointed commander-in-chief of Barbadoes and the Leeward Islands. His first exploit after this appointment was on the 8th of January ensuing, when he took sixteen Spanish transports, together with seven ships and vessels of war, which had left St Sebastian's a week before. On the 16th of the same month he fell in with the Spanish fleet, consisting of eleven sail of the line, under the command of Don Juan de Langara, of which one was blown up during the engagement, five were taken, and carried into Gibraltar, among which was the admiral's ship, and the rest were

much shattered. In April the same year he fell in with the French fleet, under the command of Admiral Guichan, at Martinique, which he fought, and beat; though, from the shattered state of his own fleet, and the unwillingness of the enemy to risk another action, he took none of their ships. The successful efforts of the gallant admiral during the year 1780 were generally applauded throughout the nation. He received the thanks of both houses of Parliament, and addresses of thanks from various parts of Great Britain, and the islands to which his victories were more particularly serviceable. In December the same year he made an unsuccessful attempt, together with General Vaughan, on St Vincent's. In 1781 he continued his exertions, with much success, in defending the West Indian Islands; and, along with the above-named general, he conquered St Eustatius, on which occasion his conduct to the inhabitants has been much, though perhaps unjustly, censured. The island was certainly a nest of contraband traders. On the 12th of April 1782, he came to a close action with the French fleet under Count de Grasse; during which he sunk one ship and took five, of which the admiral's ship, the *Ville de Paris*, was one. On the 22d of May the thanks of both houses of Parliament were voted to the admiral, his officers, and seamen, for this brilliant and decisive victory. He was appointed vice-admiral of Great Britain, and was raised to the peerage by the title of Baron Rodney of Stoke in Somersetshire. The House of Commons voted him an annual pension of L.2000. In the year 1793 this pension was permanently settled on the title; and in 1806 a pension of L.1000 Irish was granted to his grandson for life. Having been superseded very ungraciously in his command, Lord Rodney once more steered a homeward course. He landed at Bristol on the 15th of September 1782, and next day proceeded to join his family at Purbrook near Portsmouth. He survived for ten years, having died on the 24th of May 1792, after he had completed the seventy-fourth year of his age.

Lord Rodney was twice married; first to the sister of the Earl of Northampton, and next to the daughter of John Clies, Esq., with whom he did not reside for several years before his death. (See *The Life and Correspondence of the late Admiral Rodney*, by Major-General Mundy, his lordship's son-in-law, London, 1830, 2 vols. 8vo.)

RODOSTO, or RODOSJIG (anc. *Rhædestus*, or *Bisanthe*), a town of European Turkey, Roumelia, on a picturesque bay on the Sea of Marmora, 77 miles W. of Constantinople. It is defended by walls and towers, and contains many good streets, several mosques, and a large covered bazaar. There is here a harbour, by means of which an active trade in corn, wine, &c., is carried on. In the surrounding country there are many extensive gardens, from which large quantities of fruits and vegetables are sent to the town. Fishing is also carried on to some extent. Pop. 26,000.

RODRIGUES. See MAURITIUS.

ROE, the seed or spawn of fish. (See ICHTHYOLOGY.)

ROEBUCK, JOHN, the son of a Sheffield manufacturer, was born in 1718. After an elementary training, he was placed under the tuition of Dr Doddridge. Passing from this academy, he entered the university of Edinburgh, where he distinguished himself by his logical and metaphysical acuteness, and by great ingenuity in his arguments. Here he formed an acquaintance with Dr Robertson, Mr Hume, and other literary characters. Having completed his medical course at Edinburgh, he afterwards spent some time at the university of Leyden, where in 1743 he took the degree of M.D. Returning to England he commenced practice as a physician at Birmingham. Having substituted leaden vessels in the room of glass ones in the manufacture of sulphuric acid, he was enabled to sell it at a much cheaper rate than had been

Rodosto

||
Roebuck.

Roemer. lone hitherto. He accordingly established a manufactory of this material at Prestonpans in the year 1749, which was opposed by Dr Ward, but without success, as Roebuck's discovery did not come within Ward's patent. Dr Roebuck and his partner retained the advantages of their industry and ingenuity for a number of years, supplying the public with sulphuric acid at a much cheaper rate than had been formerly done. He found it expedient to relinquish his medical profession, and he resided in Scotland during the greater part of the year. He made some discoveries in the smelting of ironstone, greatly facilitating that process by using pit-coal instead of charcoal. He and his partner therefore projected a very extensive manufactory of iron, for which they soon procured a sufficient capital, as their friends had much confidence in their integrity and abilities. Dr Roebuck at length made choice of a spot on the banks of the River Carron as the most advantageous situation for the establishment of their manufactory, abundance of ironstone, limestone, and coal being found in its immediate vicinity. The preparations for this establishment were finished in the end of the year 1759; the first furnace was blown on the 1st of January 1760; and a second was soon afterwards erected. These works turned the attention of Dr Roebuck to the state of coal in the neighbourhood, and to the means of procuring the extraordinary supplies which the iron-works might require. He therefore became lessee of the extensive coal and salt works at Borrowstounness, the property of the Duke of Hamilton, in which he sunk, in the course of a few years, not only his own and a considerable part of his wife's fortune, but the regular profits of his more successful works; and, what distressed him above everything else, the great sums of money which he borrowed from his relations and friends, without the prospect of ever being able to repay them. This ruinous adventure cut off for ever the flattering prospects of an independent fortune which his family had once cherished; and he drew from his colliery only a moderate annual support, for which he was indebted to the indulgence of his creditors. It was while engaged in this speculation that he became acquainted with James Watt, the inventor of the modern steam-engine. Some years before his death, he was seized with a disorder that required a dangerous operation, which he bore, however, with his usual spirit and resolution. He visited his works till within a few weeks of his decease, which took place on the 17th July 1794. A pretty copious memoir of Roebuck appeared in the fourth volume of the *Transactions of the Royal Society of Edinburgh*, of which he was a fellow, in which it is stated that, besides contributing a few papers to that society, as well as to the Royal Society of London, he was likewise the author of two political pamphlets.

The present John Arthur Roebuck, M.P., is the grandson of Dr Roebuck.

ROEMER, OLAVUS, a celebrated Danish mathematician and astronomer, was born at Arhusen in Jutland in the year 1644, and was sent to the university of Copenhagen at the age of eighteen. By assiduous application to the study of astronomy and mathematics, he became so eminent in those sciences that Picard was astonished and delighted with him, when making observations in the north, by the order of Louis XIV. He was prevailed on to accompany Picard to France, and being presented to the king, he was chosen the Dauphin's tutor in the study of mathematics. He was afterwards united with Picard and J. D. Cassini in making astronomical observations, and became a member of the Academy of Sciences in 1672. His discoveries acquired for him great reputation during his ten years' residence at Paris; and he did not scruple to assert that Picard and Cassini took the merit of many things which belonged exclusively to himself. Roemer was the first person who discovered the velocity with which

light moves, by means of the eclipses of Jupiter's satellites, determining it to be about seven or eight minutes in coming from the sun to the earth. (See DISSERTATION FOURTH.) This opinion was opposed by many, but it was afterwards demonstrated in a most ingenious manner by Dr Bradley.

Christian V., King of Denmark, recalled Roemer to his native country in the year 1681, when he was appointed professor of astronomy at Copenhagen. He was likewise employed in the reformation of the coin and architecture of the country, in regulating the weights and measures, and in laying out the high roads throughout the kingdom. The consequence was, that the king bestowed many dignities upon him, and among others appointed him chancellor of the exchequer. In fine, he was made councillor of state and burgomaster of Copenhagen under Frederic IV., who succeeded Christian. While Roemer was engaged in preparing to publish the result of his observations, he was cut off on the 19th of September 1710, when about sixty-six years of age. Horrebow, his disciple and successor in the chair of astronomy, made up this loss by publishing, in 4to, in 1753, various observations of Roemer, with his method of observing, under the title of *Basis Astronomiæ*. He had printed various astronomical observations and pieces in several volumes of the *Memoirs of the Royal Academy of Sciences* at Paris. (See ASTRONOMY, *History of*; and MICROMETER.)

ROERMONDE (Fr. *Ruremonde*), a strongly-fortified town in the Dutch province of Limburg, at the confluence of the Roer with the Maas or Meuse, 28 miles N. by E. of Maestricht. It has broad, regular streets, and a fine bridge across the Roer, leading to the suburb of St Jacob. The chief buildings are the cathedral in the Byzantine style, episcopal palace, spacious town-hall, convent, and hospital. There are here a college and several schools. Woollen cloth, silk, paper, leather, and beer are manufactured, and there are also bleach-fields, dye-works, flour-mills, &c. Pop. (1850) 7172.

ROGATION-WEEK, the week immediately succeeding Whitsunday; so called from the three feasts therein, viz., on Monday, Tuesday, and Wednesday.

ROGER DE HOVEDEN. See HOVEDEN.

ROGER DE WENDOVER, who was a monk in the abbey of St Albans, and who died prior of Belvoir in 1237, left behind him a Latin chronicle entitled *Flores Historiarum* ("The Flowers of History"). It is a history of the world from the creation to 1235, and is usually considered by critics as divided into three parts. The first part, which treats of all events before A.D. 447, is taken bodily from the Greek and Roman historians, and from Geoffrey of Monmouth, and is of little or no value. The second part, bringing the narrative down to about 1200, is copied from many of the best of preceding chronicles, and is worthy of being preserved on account of its extracts from numerous works which are now lost. The last part, recording the events which happened within the author's own sight or hearing, is precious as an original history of that age. The Chronicle of Roger de Wendover, with the exception of the first part, has been edited by the Rev. H. C. Coxe, in 4 vols. 8vo, London, 1841-42. An English translation, published in 1849 by Dr J. A. Giles, forms two volumes of Bohn's "Antiquarian Library." Matthew of Paris incorporated, with few alterations, the *Flowers of History* into his own Chronicle.

ROGERS, SAMUEL, an English poet of refined taste and feeling, and for more than half a century greatly distinguished in London society, was born at Newington Green on the 30th of July 1763. He was descended from a Worcestershire family, his grandfather being Thomas Rogers, of the Hill, near Stourbridge. His father settled in London as a banker, and was head of the firm long carried on under the name of Rogers, Olding, & Co., Clement's

Roermonde
||
Rogers.

Rogers. Lane. By the maternal side the poet was connected with the English Nonconformists. His mother, Mary Radford, was the grand-daughter of Eleanor, daughter of Philip Henry, and sister of Matthew Henry—both eminent Nonconformist divines. The poet's mother, "a very handsome and very amiable woman," persuaded his father to withdraw from the Church of England, and become a member of the Presbyterian church at Newington, of which Dr Price was the pastor. Price, though described by his adversary Burke, as "a man much connected with literary caballers and intriguing philosophers, with political theologians and theological politicians," was eloquent, courteous, and polished in his manners; and to this dissenting connection the poet was indebted for his introduction to many of the eminent Whig politicians and men of rank whom he was afterwards proud to number among his friends. In mature life he did not care to rank with the dissenters; but he never abjured the association, and the last note in his poem of *Italy* tells us that his original MS. of the poem contained these lines:—

"What though his ancestors, early or late,
Were not ennobled by the breath of kings;
Yet in his veins was running at his birth
The blood of those most eminent of old
For wisdom, virtue—those who could renounce
The things of this world for their conscience sake,
And die like blessed martyrs"¹

Mr Rogers was educated at the Newington Green academy, then taught by a Dr Burgh, author of a treatise on the *Dignity of Human Nature*. One of his school-fellows was Mr William Maltby, a modest and retired scholar, who succeeded Porson as librarian to the London Institution, and lived to the age of ninety, enjoying the friendship of the poet. The latter was fond of relating that one day he and Maltby, while walking up Fleet Street, resolved on visiting Johnson in Bolt Court, and introducing themselves to the great literary dictator; but when Rogers' hand was on the knocker of the door his heart failed him, and the young aspirants withdrew. Boswell, to whom many years afterwards Mr Rogers related the circumstance, said truly "Why did you not go boldly in? He would have received you with all kindness." And such, no doubt, would have been the result. Johnson never appeared to greater advantage than when giving advice and counselling his young and diffident admirers. The first ambition of Rogers was to be a preacher—a second Dr Price; but his father placed him in his own banking-house, preparatory to his being admitted as a partner. He read Gray and Goldsmith as he walked to and from the bank in Cornhill; yet when he ventured on authorship his first appearance was in prose. He contributed a series of essays, entitled the *Scribbler*, to that venerable repository of fugitive literature, the *Gentleman's Magazine*. This was in 1781, when Rogers was in his eighteenth year. The essays are in the usual formal didactic style of that period, and are neatly written. In 1786 he published his *Ode to Superstition, with some other Poems*, paying down a sum of L.30 to the publisher to secure him from loss; and the precaution was not unneeded, as at the end of four years only about twenty copies of the

work (1s. 6d. each) were sold. The *Monthly Review*, however, recognised in the crude imitations of Gray and Dryden, "the hand of an able master," and Rogers confessed that this praise was the first stimulant to his ambition. In 1789 he visited Edinburgh (travelling on horseback), and was introduced to Adam Smith, Blair, Robertson, and Henry Mackenzie. He afterwards regretted that he had not rode on to Ellisland to visit Burns, but some of his Edinburgh friends, he said, dissuaded him from the journey. Part of 1790–91 he spent in Paris, and the year following his return witnessed his advent as a successful poet. His *Pleasures of Memory* appeared in 1792, at first anonymously, but the author becoming known, he was fêted and applauded. "What pleasure I felt," he said, "on being told that Este (Parson Este) had said of me, 'A child of Goldsmith, Sir.'" Este was one of the royal chaplains, an author, and a proprietor of the *Morning Post* and *World* newspapers. He was an authority in fashionable circles, and his favourable award must have appeared fame. In this instance Mr Este was right. The *Pleasures of Memory* belong to the school of Goldsmith. The versification, the pensive vein of reflection, the concise, select imagery and description, show that the poet had carefully studied the *Traveller* and *Deserted Village*—superadding, however, a strain of subtle and refined thought, with historic and classic allusions which peculiarly mark the poetry of Rogers. "His elegance is really wonderful," said Byron; "there is no such thing as a vulgar line in his book." It must be admitted, however, that there are several feeble lines in the poem, with a few half-formed pictures, and passages which recall the more vigorous and fervent inspiration of older masters. In 1793 the poet's father died—his mother he had early lost; and he withdrew in great measure from the banking-house, leaving the management to a younger brother. About the same time he removed from Newington Green to apartments in the Temple, which he furnished with great elegance. His taste in all matters relating to social life may be seen from his *Epistle to a Friend*, printed with a few other poems in 1798. In his rooms in the Temple the poet lived till about the year 1803, when he removed to a house in St James's Place, looking into the Green Park. This house—the celebrated No. 22 St James's Place—he had altered and nearly rebuilt according to his own taste, and there he entertained his friends of every class and country (Charles James Fox was his first dinner guest), and accumulated those treasures of art,—pictures, books, autographs, gems, vases, and antiques of all descriptions, rich and rare, which, on his death, were dispersed after a sale of twenty-two days, producing upwards of L.50,000. Mere wealth could not have amassed such a collection. It was the result of taste and knowledge, combined with the judicious expenditure of money at the right time, and constant vigilance in watching the proper opportunity. Some of those treasures, we are happy to add, have, by the liberality of their owner, found their way into the National Gallery and British Museum. The poet was never married. In 1812 Rogers published a collection of his poems, including in the volume a new piece, *The Voyage of Columbus*, professing to be translated from the original in the

¹ The poet's nephew, Mr Samuel Sharpe (author of the *History of Egypt, &c.*), has illustrated this part of the poet's history with some characteristic anecdotes. When walking one day through Hanover Square with Mr Luttrell, the witty conversationist, and author of *Letters to Julia*, and coming down upon St George's Church, Rogers remarked on the inconvenience of being thrust off the pavement and made to cross the street by the projecting portico. "Ah," exclaimed Luttrell, "that comes of your dissenting principles." On another occasion, when Wordsworth and Rogers were walking through York Minster, the latter descanted on the fitness of the great pile to awaken religious feelings in the mind, when Wordsworth stoutly and rather rudely denied that his companion could admire it equally with himself, because of his Presbyterian education! When the Dissenters' Chapel Bill was before the House of Commons, Mr Sharpe called upon Mr (now Lord) Macaulay to ask him to present a petition signed by the descendants of Philip Henry. "Has my friend Rogers signed it?" asked Macaulay, thus marking his knowledge of family history, and of the fact of Mr Rogers being a descendant of the ejected Nonconformist divine. Rogers' connection with the Presbyterians was something like that of Pope with the Roman Catholics. But he never forgot his early minister, Dr Price; and until within a fortnight of his death it always afforded him pleasure to hear his favourite servant or librarian, Edmund Payne, read one of Price's sermons.

Rogers. Castilian language. This poem is a series of fragmentary sketches, with supernatural machinery, neither very appropriate nor well executed, but containing some imagery and couplets of great picturesqueness and beauty. Mr Ward (afterwards Lord Dudley) reviewed the volume in the *Quarterly Review*, March 1813, in a style of studied yet veiled depreciation, which provoked the poet to retaliate in that inimitable epigram—

“Ward has no heart they say, but I deny it;
He has a heart, and gets his speeches by it.”

The little tale of *Jacqueline*, published in conjunction with Byron's *Lara*, in 1814, was Rogers's next work; and he made no other public appearance until 1819, when his poem of *Human Life* was published. This is the most truly poetical of all his works—as highly finished as the *Pleasures of Memory*, but with deeper feeling and profounder philosophy. His pictures of the different epochs or phases of life,—the noble aspirations of youth—the struggles of patriotism—the various passions, hopes and fears, joys and sorrows, that chequer existence, until the last scene, when “earth recedes and heaven itself appears,”—are touched with a moral beauty, pathos, and refinement of sentiment and expression, that none of his contemporaries have equalled. That the poem is not more popular arises from its delicacy and excessive refinement. It wants the energy of strong passion and the interest of a narrative or consecutive series of incidents; but, as has been said of the kindred poetry of Gray, “when we give its beauties re-perusal and attention, they kindle and multiply to the view.” There is greater variety in his next work *Italy*, but less genuine poetry. The first part of *Italy* was published anonymously in 1822, and other parts followed at intervals; the whole work, he said, not being completed in less than sixteen years. The *Pleasures of Memory* occupied him for nine years, and *Human Life* nearly the same space of time. He used to say, “The time when I consider that I wrote with the least difficulty was about the period of the death of Fox. Then I felt myself equal to anything, and it was then I wrote such lines as these:—

The clouds that rise to quench the orb of day
Reflect its splendour, and dissolve away.

I never wrote better.” Yet this image is directly borrowed from Pope (*Essay on Criticism*, v. 466–473), and much finer lines, original and drawn from nature, will be found both in *Memory* and in *Human Life*. The blank verse of *Italy* is easy and unconstrained, at times sliding into the ordinary language of good conversation, and some charming episodes and anecdotes are introduced along with those descriptions that specially interest the classic student and virtuoso. The poem might appropriately be bound up with Forsyth's *Remarks on the Arts and Antiquities of Italy*, the two works forming a storehouse of fine thoughts and observations and well-digested knowledge, symmetrized and adjusted by consummate taste. The prose of Rogers' notes is as exquisite as his verse, and was written with equal care and fastidiousness. He wrote slowly and corrected elaborately, from a desire, he said, to make his compositions so simple that a child might understand them. There are instances in which he wrote his lines over thirty and even forty different ways in order to get rid of all big words.

“My best lines,” he would remark, “are monosyllabic: small bricks make the stoutest walls.” In quoting from other authors, in notes to his poems, he took the same liberty of rejection and condensation; passages from Mrs Inchbald, and even from Burke, having been subjected to this process, and not always to their advantage. An author of greater power and more robust intellect, animated by the fire of genius, would of course have discarded such rules and restraints, and flung himself boldly into his subject, but with Rogers, as with Akenside, taste was the predominating faculty, and in both it was united to the perception and enjoyment, though without enthusiasm, of the good and the beautiful in art and nature. “True taste,” he says, “is an excellent economist. She confines her choice to few objects, and delights in producing great effects by small means; whilst false taste is for ever sighing after the new and the rare; and reminds us, in her works, of the scholar of Apelles, who, not being able to paint his Helen beautiful, determined to make her fine.” Byron considered that Rogers' highly-cultivated taste and his sensibility must have often rendered him discontented and miserable. He notices, in his diary, his friend's silence, his severity, the perfect arrangements of his house; not a gem, a coin, a book thrown aside on his chimney-piece, his sofa, or table, that did not bespeak an almost fastidious elegance in the possessor. “But this very delicacy,” adds the noble poet, “must be the misery of his existence. Oh, the jarrings his disposition must have encountered through life!” Now Rogers spent much of his time in reading and composition, in the society of the witty, the beautiful, the accomplished, and the learned; he was rich and benevolent, and surrounded by all the luxuries and attractions he most prized. Such a man so occupied and in such “blessed conditions” of fortune and fame, joined to a philosophical and somewhat epicurean frame of mind, could not be long or frequently unhappy. We would rather say that he enjoyed as many hours and days of solid happiness and comfort as are allotted to mankind, and infinitely more than most of his gifted contemporaries (Wordsworth excepted) could ever realize. His sources of enjoyment were more various, and his capacity to appreciate them higher than those of most men; and from some of the worst ills of life—its sordid cares and anxieties—he was wholly exempt. Late in his prosperous career a cloud seemed to come over his fortunes. His banking-house was robbed of a large sum, and the loss was likely to be disastrous. The greater part of the stolen money was, however, recovered; and the generosity with which his friends came forward with offers of assistance—“one nobleman placing L.10,000, a second L.30,000, and a third (a merchant prince) L.100,000 at his disposal”—must have afforded him the most exquisite gratification. The severity which Byron charges against his old friend was not imaginary. He did not, indeed, like Byron himself, “libel his friends all round,” but he often gave them cause for uneasiness and alarm by his habit of fault-finding and saying bitter things couched in calm and measured language. His caustic observations and quiet, stinging sarcasm were feared—his pointed sayings were repeated—and he was thus formidable as well as popular in society.² Such personal sallies

Rogers.

¹ *Edinburgh Review*, July 1856. The essay on Rogers in the *Review* is by Mr Hayward, Q.C., and has since been included in two volumes of Essays published by its accomplished author.

² In Stafford House is a large painting by Murillo of “Abraham entertaining the Angels.” The angelic personages of the great artist have nothing very heavenly in their aspect or appearance; and Rogers, on looking at the picture, said, “I do not wonder at Abraham entertaining the angels *unaware*.” This may give some idea of his studied sarcastic brevity of criticism; but in such things the *manner* of the saying is nearly as important as the *matter*. Some of Rogers' *mots* will be found in Moore's Journals. The following, still better, are from Mr Hayward's essay:—When he was speaking of some one's marriage in his usual tone, he was reminded that the friends of the bridegroom were very much pleased at it; Rogers replied, “He is a fortunate man, then, for his friends are pleased and his enemies delighted.” When a late member for a western county and his wife were stopped by banditti in Italy, Rogers used to say, “The banditti wanted to carry off P—— into the mountains; but she flung her arms round his neck, and rather than take her with them, they let him go.” Rogers was unsuccessfully at war with the late Lady D. One day at dinner she called across the table, “Now, Mr Rogers, I am sure you are talking about me.” “Lady D.,” was the retort, “I pass my life in defending you.”

Rogers.

were common among the wits of his youth, or had descended from the days of Chesterfield and Selwyn; and though in Rogers' case there were undoubtedly flaws of temper as well as the desire to shine and win his way by severity, his habitual politeness and active benevolence operated as powerful checks on the unamiable propensity. Of his income of L.4000 or L.5000 a year, at least L.1500 (according to Thomas Campbell), were spent in relieving distress, or helping onwards modest merit and struggling talent. He cheered the death-bed of Sheridan by his generosity; and in all emergencies his literary friends, including Moore and Campbell, found him a frank and liberal assistant. Instances of this kind are recorded in various memoirs and diaries, but as the poet's friend Mr Dyce has said, "Of his many acts of kindness and charity to the wholly obscure there is no memorial—at least on earth." We may therefore set the life-long kind actions against the occasional bitter words, and in *their* light and warmth the temporary blot will soon vanish. Whatever were Rogers' defects or infirmities, he made no effort to conceal them. No man ever lived more in society or was more communicative in conversation. His breakfast and dinner parties were famous; he held literary levees almost daily; and his classic mansion was thrown open not only to friends, but to strangers, who eagerly sought introduction to the patriarch poet and patron of literature and art. Anecdote and criticism were the favourite topics of the host. He loved to read and expatiate on choice passages in old authors, or characteristic features in the productions of great artists; and though latterly he expected the deference of being allowed to dictate or introduce the topic of conversation, all were invited to mingle in it. Mr Hayward has felicitously sketched the interior of this Tusculum of St James's Place:—

"There, surrounded by the choicest treasures of art, and in a light reflected from Guidos and Titians, have sat and mingled in familiar converse the most eminent poets, actors, artists, critics, travellers, historians, warriors, orators, and statesmen of two generations. Under that roof celebrities of all sorts, matured or budding, and however contrasted in genius or pursuits, met as on the table-land where (according to D'Alembert) Archimedes and Homer may stand on a perfect footing of equality. The man of mind was introduced to the man of action, and modest merit, which had yet its laurels to win, was first brought acquainted with the patron who was to push its fortunes, or with the hero whose name sounded like a trumpet-note. It was in that dining-room that Erskine told the story of his first brief, and Grattan that of his last duel; that the 'Iron Duke' described Waterloo as a 'battle of giants'; that Chantrey, placing his hand on a mahogany pedestal, said, 'Mr Rogers, do you recollect a workman at five shillings a day who came in at that door to receive your orders for this work? I was that workman.' It was there, too, that Byron's intimacy with Moore commenced over the famous mess of potatoes and vinegar; that Madame de Staël, after a triumphant argument with Mackintosh, was (as recorded by Byron) 'well ironed by Sheridan'; that Sydney Smith, at dinner with Walter Scott, Campbell, Moore, Wordsworth, and Washington Irving, declared that he and Irving, if the only prose writers, were not the only prosers in the company. It was through that window, opening to the floor, and leading through the garden to the park, that the host started with Sheridan's gifted grand-daughter (Mrs Norton) on 'The Winter's Walk,' which she has so gracefully and feelingly commemorated. It was in the library above that Wordsworth, holding up the original contract for the copyright of *Paradise Lost* (1300 copies for L.5), proved to his own entire satisfaction that solid fame was in an inverse ratio to popularity; whilst Coleridge, with his finger upon the parchment deed by which Dryden

Rohan.

agreed for the translation of the *Æneid*, expatiated on the advantages which would have accrued to literature if 'glorious John' had selected the *Iliad* and left Virgil to Pope."

These ever-shifting and brilliant scenes have now "gone glittering through the dream of things that were:" and of all the actors, one only, the fair poetess, remains. But in thus dispensing his refined and lettered hospitality, in assembling parties who might otherwise have never met, in healing differences, and bringing forward talent struggling into notice, Mr Rogers performed one of the noblest duties of a citizen, worthy, for the sake of example, of imperishable record. It is to be regretted that no Boswell was present at these gatherings. The host himself took occasional notes of the opinions and remarks of some of the more illustrious of his friends; and his recollections of Fox, Grattan, Porson, Hoine Tooke, Erskine, and the Duke of Wellington, have been published by his nephew, Mr William Sharpe; but the collection is small, desultory, and imperfect,—a not unpleasant table-book, but a feeble illustration of the intellectual powers or moral qualities of the great men commemorated.

The illustrated editions of his *Italy* and *Poems* formed Mr Rogers' last public work. He called in the genius of Turner and Stothard, and the talent of the best engravers, expending on the two volumes, besides his own ceaseless care and taste, a sum of about L.15,000; but the undertaking proved remunerative, and the books are still unsurpassed among our illustrated publications. In 1850, on the death of Wordsworth, the post of laureate was offered to Rogers, and pressed on his acceptance by Prince Albert; but he was then eighty-seven, fit only for the Court of Death, though happily not surrounded by any of "the gloomy attendants of his reign." He declined the appointment, and it was worthily bestowed on Mr Tennyson. A few weeks afterwards, in June 1850, the aged poet met with an accident, a fall in the street, which ever afterwards confined him to his chair. As he had all his life been a great walker, and was remarkable for the amount of exercise he could accomplish in one day,—visiting distant friends, dining out, or receiving company, attending the opera, and finishing off at a ball,—the want of locomotion was a sad privation. But books, friends, and pictures were still left: he could take his daily drive, or he could be wheeled out to the garden or park to witness the sunsets which he so much admired; and the orb of day never declined more gently, or shaded more imperceptibly into final obscurity, than this Nestor of poets journeyed downwards to the grave. He died on the 18th of December 1855, being then in his ninety-third year, and was buried at Hornsey. (R.C.—S.)

ROHAN, HENRI, *Duc de*, peer of France, and prince of Leon, was born at the Chateau de Blein, in Brittany, in 1579. Henri IV., under whose eye he gave distinguished proofs of his bravery at the siege of Amiens, when only sixteen years of age, loved him with as much affection as if he had been his own son. After the death of Henry, he became chief of the Calvinists in France; and was equally formidable for his genius as for his sword. In defence of the civil and religious rights of his party, he maintained three wars against Louis XIII. The first, which terminated to the advantage of the Protestants, broke out when that prince wished to establish the Romish religion in Bearn; the second, because of the siege which Cardinal de Richelieu ordered to be laid to Rochelle; and the third, when that place was besieged a second time. The consequences of this war are sufficiently known: Rochelle surrendered, and the Duc de Rohan, perceiving that, after the taking of this place, the majority of his party were endeavouring to make up matters with the court, succeeded in procuring for them a general peace in 1629, upon very honourable and advantageous terms. There is an anecdote told of him, in the *Memoirs of the Duchess of Rohan*, Mar-

Rohault. garet of Bethune, daughter of the famous Sully. While the Duc de Rohan was at Venice, a proposal was made to him from the Porte, that for 200,000 crowns, and an annual tribute of 60,000 livres, the grand seignior would give him the island of Cyprus, and fully invest him with the dignity and prerogative of king. The duke was warmly inclined to comply with this proposal, and to settle in the island the Protestant families of France and Germany. He negotiated this business at the Porte by means of the intervention of the patriarch Cyril, with whom he had much correspondence; but different circumstances, and in particular the death of the patriarch, contributed to break off the treaty. The republic of Venice chose Rohan for their commander-in-chief against the imperialists; but Louis XIII. took him from the Venetians, and sent him ambassador into Switzerland, and into the Grisons. He wished to assist these people in reducing La Valteline to obedience, the revolt of which the Spaniards and imperialists encouraged. Rohan being declared general of the Grisons, after many victories, drove the German and Spanish troops entirely from La Valteline in 1633. He again defeated the Spaniards in 1636, at the banks of the Lake of Como. France, not thinking it proper to withdraw her troops, the Grisons rose up in arms; and the Duc de Rohan, not satisfied with the conduct of the court, entered into a special treaty with them on the 28th of March 1637. Thus hero, fearing the resentment of Cardinal de Richelieu, retired to Geneva, with a view of joining his friend the Duke of Saxe-Weimar, who wished him to undertake the command of his army, then ready to engage the imperialists near Rhinfeldt. Although he declined this honour, yet he took the command of the regiment of Nassau, with which he threw the enemy into confusion; but was himself wounded, 28th February 1638, and died the 13th of April following, at the age of fifty-nine. He wrote several interesting performances:—*Les Entretiens des Princes*, printed at Cologne in 1666, in 12mo. *Le parfait Capitaine*, or an abridgment of the wars from Cæsar's Commentaries, in 12mo. *Traité de la Corruption de la Milice Ancienne; Traité de Gouvernement des 13 Cantons*; also *Mémoires*. They contain the history of France from 1610 to 1629. *Recueil de quelques Discours Politiques sur les Affaires d'Etat*, from 1612 to 1629, 8vo, Paris, 1644, 1693, 1755; with *Mémoires et Lettres de Henri, Duc de Rohan, sur la Guerre de la Valteline*, 3 vols. 12mo, Geneva, 1757. This was the first edition which appeared of these curious memoirs: we owe it to the great attention and diligence of Baron de Zurlauben, who published them from different authentic manuscripts, with a highly interesting Life of the noble author.

ROHAULT, JACQUES, one of the first and most zealous propagators of the Cartesian philosophy in France, was born at Amiens in 1620. He was early conveyed to Paris, where he showed a decided predilection for philosophical pursuits. So high did he rank in the esteem of his masters that Clerselier gave him his daughter in marriage. He continued to teach in Paris with great reputation for ten or twelve years. In 1771 he published a *Traité du Physique*, which enjoyed an immense reputation both in and out of France. It was translated into Latin by Dr Samuel Clarke, who corrected the Cartesian predilections of the author by the more sound investigations of Newton. Rohault was likewise the author of a small book, *Entretiens de Philosophie*, in which he endeavoured to meet the objections of all parties to the writings of his master Descartes. He died in 1672, and was buried at Sainte-Geneviève, beside him in whose interest he had spent his life. (See Clerselier's preface to the second volume of his *Lettres de Descartes*; and the *Œuvres Posthumes* of Rohault, 4to, Paris, 1682. The reader may likewise consult Damiron's *Histoire de la Philosophie du 17 Siècle*; and the *Dictionnaire des Sciences Philosophiques*.)

VOL. XIX.

ROHILCUND, a name given to a tract of country in British India, presidency of Bengal, lying between N. Lat. 27. 15. and 29. 51., E. Long. 73. 3. and 80. 30.; bounded on the N. by British Gurwhal and Kumaon, E. by Oude, S. and W. by the Ganges, which separates it from the Doab. It comprises the British districts of Bijnour, Moradabad, Pilleebheet, Bareilly, Budaoon, and Shajehanpoor, with the native jaghire of Rampoor. Area 12,428; pop. 5,217,507, of whom 4,036,166 are Hindus. The country is fertile, traversed by numerous rivers, and has a very good climate. The soil is watered with much care by artificial means, and produces large quantities of corn, sugar, and tobacco. There are also extensive saul forests, and this timber forms one of the principal articles of exportation. The country derives its name from its former rulers, the Rohillas, an Afghan people who invaded India, and established themselves in the N.W. of Oude about 1747. Vain efforts were made by several nabobs of Oude to subdue this military colony, which, though disunited except for defence, could bring 80,000 men into the field. But their most formidable enemies were the Mahrattas; and, as these were equally hostile to Oude, an alliance was made in 1773 between the Rohillas, the nabob of Oude, and the British, by means of which the Mahratta forces were repulsed. Thereupon the nabob, by his exorbitant demands, made a pretext for subduing Rohilcund; an enterprise which, to the disgrace of the British name, was made successful by a body of troops lent by Warren Hastings. The country was ravaged and plundered by the cruel and cowardly followers of the nabob, and the Rohillas were, with few exceptions, exterminated or expelled. Rohilcund was afterwards ceded to the British in 1801.

ROLAND, MANON JEANNE PHILIPON, the great heroine of the French Revolution, was the only surviving child of Philipon, an engraver, and was born at Paris in 1754. In her quiet home on the Quai des Orfèvres, and amid the routine of humble household duties, the young girl began to develop her earnest nature. The budding beauty of her person was but a faint shadow of the serene and noble spirit that was moving within. She sought after truth with all the devoted affection of a lover. Through history, theology, philosophy, and the sciences her vigorous mind wandered, fixing upon whatever gratified her pure and elevated tastes. Especially did her attention love to rest upon the ancient ages as portrayed in Plutarch's *Lives*. Dwelling in spirit in those great times, her conduct became imbued with the severe magnanimity of an old Greek or Roman. She abjured everything but what was true and uprightly noble. The rites of the priests seemed hollow mockeries, and she abandoned the Christian religion. The gilded vices of the aristocracy roused her indignation; and she turned a confirmed republican. Nor did she act less consistently when, about the age of twenty, she began to be assailed by offers of marriage. The crowd of volatile suitors who were attracted by her charms did not excite her vanity. She rejected the whole tribe, one after another, with unhesitating candour. In vain did her father remonstrate with her. "It is not a position," she said, "but a mind that I want." The only person that was able to affect her well-disciplined heart was Jean Marie Roland de la Platière, inspector of manufactures at Amiens, a grave, middle-aged philosopher, weather-beaten and thought-worn, coldly virtuous as a Spartan, and sternly patriotic as a Cato. She therefore gave him her hand about her twenty-fifth year, and thenceforth devoted herself entirely to his stern will.

Madame Roland was in Paris in the early part of 1792, occupying a prominent place among the revolutionists. Her husband had been deputed to the Constituent Assembly by the city of Lyons. His honest patriotism had raised him to a high place among the reformers; and when

Rolle.

a Girondist cabinet had been forced upon the royal choice, he had been appointed minister of the Interior. Accordingly she was now living in the official saloon, and giving ministerial dinners twice a week. On these occasions she was wont to exercise all the spontaneous power of a queen. No sooner had her guests entered than they felt the captivating effect of her mature beauty and flashing genius. As they sat at table they could not help being inspired with her noble enthusiasm and wise political views. When the cloth had been removed they were still sensible of her influence, although she sat silently apart at her work-table; and they were ready to moderate their hot discussions whenever she prudently interposed. In fact, she was the very soul of the Girondist party.

The spirit of Madame Roland appeared in all its serene greatness when, on the fall of her faction, she was cast into prison by the triumphant Jacobins. The remorseless gripe of her enemies, the axe ready at any moment to fall upon her head, and the unknown gulf on the other side of death, did not daunt her soul. Her mind, like that of a brave pagan, dwelt upon the grand vision of human magnanimity. She lived over again, and recorded, in a series of *Mémoires*, her previous life of self-sacrifice and patriotism. She also summoned up from the pages of her favourite Plutarch the great deeds and death-scenes of the past. It is true that the thought of her little girl, left so early without a mother's care, of her infirm husband fleeing before his blood-thirsty enemies, and of herself doomed to a premature and unjust end, sometimes proved too strong for her womanly heart, and made her burst into tears. Yet at other times, looking through the grating of her window, she addressed the prisoners in the court-yard of the Conciergerie, and, like a very angel of liberty, spoke with an eloquence so refined and musical that the poor doomed victims of the Revolution stood charmed on the spot for hours together, and then went away to their cells shouting "*Vive la République*."

On the 8th November 1793, the last day of her life, the demeanour of the brave Roland was more heroically subdued than ever. After hearing herself sentenced to be guillotined, she thanked her judges that they had sent her to share the same fate as those brave men whom they had recently murdered. She then ran down stairs from the judgment-hall to her cell as if making haste to be gone. The preparation was soon over; and she appeared in the condemned cart calm and beautiful, a perfect statue of innocence, clad in white, and with her raven hair flowing down in thick ringlets to her girdle. As the vehicle rumbled onwards to the Place de la Concorde, she stooped down amid the insults of the mob to cheer her fellow-victim, an old man, who was crying like a child. Nor did her self-possession fail when she arrived in front of the guillotine. She asked for a pen to write down "the strange thoughts that were arising within her." Then mounting the scaffold, she turned to the statue of Liberty which stood close by, and exclaimed, "O Liberty, what crimes are committed in thy name." These were her last words, and in a few moments afterwards her head fell into the basket.

Several days after the death of Madame Roland, the dead body of her husband was found in an avenue near Rouen, pierced through the heart with a long stiletto. On a scrap of paper beside it were these words:—"After my wife's murder, I would not remain any longer in a world so stained with crimes." (See *Mémoires de Madame Roland*, 2 vols., Paris, 1821; Lamartine's *Girondists*; and Carlyle's *French Revolution*.)

ROLLE, MICHEL, a French mathematician, was born at Ambert in Auvergne in 1652. Although obliged at an early age to become an attorney's clerk, all the young man's tastes were soon concentrated upon mathematics. His work, in course of time, grew intolerable to him. He

gave it up in 1675, and went to Paris to seek for a better opportunity of gratifying his master-passion. Supporting himself by teaching writing, he devoted all his spare moments to algebra. So ardently, in fact, did he labour, that his dexterity soon attracted the notice of the minister Colbert, and gained for him a pension. Rolle now entered upon a career of distinction. The recently-instituted Academy of Sciences elected him into their number in 1685. Fresh reputation was gained by his *Treatise on Algebra* in 1690, and by his *Method of resolving Indeterminate Questions in Algebra* in 1699. At length, in 1701, he came very prominently before the learned public as a pertinacious objector to the newly-discovered Differential Calculus. Boldly asserting the fallacy of that process, he attempted to show that it could not be applied to certain cases. In vain did Varignon and others prove to him that the error lay in his misapplication of the principles in question. For several years he persisted in his opposition; and it was only shortly before his death in 1719 that he confessed his mistake.

ROLLI, PAOLO ANTONIO, an Italian poet, was born at Rome in 1687. He was the son of an architect, and a pupil of the celebrated Gravina, who inspired him with a taste for learning and poetry. An intelligent and learned English peer having brought him to London, introduced him to the royal family as a master of the Tuscan language. Rolli remained in England till the death of Queen Caroline, his protectress, and the patroness of literature in general. He returned to Italy in 1747, where he died in 1767, in the eightieth year of his age, leaving behind him a very curious collection in natural history, with a valuable and well-chosen library. His principal works first appeared in London in 1735 in 8vo. They consist of odes in blank verse, elegies, songs, and other poems after the manner of Catullus. A collection of his epigrams was printed at Florence in 1776, in 8vo, to which is prefixed an account of his life by Fondini. What Martial said of his own collection may be said of this, "that there are few good, but many indifferent or bad pieces in it." He likewise translated into Italian verse the *Paradise Lost* of Milton, printed at London in folio in 1735; and the *Odes* of Anacreon, London, 1739, in 8vo.

ROLLIN, CHARLES, a celebrated French writer, was the son of a cutler at Paris, and was born there on the 30th of January 1661. He studied at the college of Pléssis, in which he obtained an exhibition through the interest of a Benedictine monk whom he had served at table, and who discovered in him some marks of genius. Here he acquired the regard of M. Gobinet, principal of the college, who had a particular esteem for him. After having studied humanity and philosophy, he applied himself to divinity three years at the Sorbonne: but he did not prosecute this study, and was satisfied with obtaining the tonsure. He afterwards became professor of rhetoric in his own college, and in 1688 succeeded his master as professor of eloquence in the Royal College. In 1694 he was chosen rector of the university, which was then a mark of distinction, and he continued in that office two years. He spoke the annual panegyric upon Louis XIV., and made many very useful regulations in the university; he revived the study of the Greek language, which was then much neglected; he substituted academical exercises in the place of tragedies; and introduced the practice, which had been formerly observed, of causing the students to get by heart passages of Scripture. He was a man of indefatigable application, and trained innumerable persons, who did honour to the church, the state, and the army. Upon the expiration of the rectorship, Cardinal Noailles engaged him to superintend the studies of his nephews, who were in the college of Laon; and in this office he was agreeably employed when, in 1699, he was, with great reluctance,

Rolli

||

Rollin.

made coadjutor to the principal of the college of Beauvais. This college was then a kind of desert, inhabited by very few students, and without any regular discipline; but Rollin's great industry soon raised it to that credit which it long retained. In this situation he continued till 1712, when the war between the Jesuits and the Jansenists drawing towards a crisis, he fell a sacrifice to the prevalence of the former. Father le Tellier, the king's confessor, a furious agent of the Jesuits, infused into his master prejudices against Rollin, whose connection with Cardinal de Noailles would alone have sufficed to make him a Jansenist; and on this account he lost his share in the principality of Beauvais. He now employed his leisure upon Quintilian, an author whom he justly valued, and could not without uneasiness see neglected. He retrenched in him whatever he thought curious rather than useful: placed summaries or contents at the head of each chapter, and accompanied the text with short and select notes. His edition appeared in 1715, in 2 vols. 12mo, with an elegant preface explaining his method and views.

In 1710 Rollin was chosen rector of the university of Paris; but he was displaced in about two months by a *lettre de cachet*. He now applied himself to the composition of his *Treatise on the Manner of Studying and Teaching the Belles Lettres*, two volumes of which were published, in 8vo, in 1726, and two more in 1728. This work, though greatly deficient in order, and displaying neither depth nor philosophy, has been exceedingly successful; and its success encouraged the author to undertake another work of equal use and entertainment, his *Ancient History of the Egyptians, Carthaginians, Assyrians, Babylonians, Medes and Persians, Macedonians and Greeks*, which he finished in 13 vols. 8vo, and published between 1730 and 1738. Voltaire, after having observed that Rollin was "the first member of the university of Paris who wrote French with dignity and correctness," says of this work, that "though the last volumes, which were written in too great a hurry, are not equal to the first, it is nevertheless the best compilation that had yet appeared in any language; because it is seldom that compilers are eloquent, and Rollin was remarkably so." This is perhaps saying too much. His chronology is neither exact nor consistent: he states facts inaccurately; he has not sufficiently examined the exaggerations of ancient historians; he often interrupts the most solemn narrations with mere trifles; and his style is not uniform. Nothing can be more noble and more refined than his reflections; but they are strewn with too sparing a hand, and want that lively and laconic turn on account of which the historians of antiquity are read with so much pleasure. There is a visible negligence in his diction with regard to grammatical usage, and the choice of his expressions, which he does not at all times select with sufficient taste, although, on the whole, he writes well, and has preserved himself free from many of the faults of modern authors. While the last volumes of his *Ancient History* were printing, he published the first of his *Roman History*, which he lived to carry on, through the eighth volume and into part of the ninth, to the war against the Cimbri, about seventy years before the battle of Actium. Crevier, the worthy disciple of Rollin, continued the history to the battle of Actium, which closes the tenth volume; and afterwards completed the original plan of Rollin in sixteen volumes 12mo, which was, to bring it down from the foundation of the city to the reign of Constantine the Great. This work is alternately diffuse and barren; and the greatest advantage of the work is, that there are several passages from Livy translated with great elegance into French. He also published a Latin translation of some of the theological writings relative to the disputes of the times in which he lived. He also published *Opuscles*, containing different letters, Latin harangues, discourses, complimentary addresses, &c.,

Paris, 1771, 2 vols. 12mo. He died in 1741. The *Œuvres de Rollin* have frequently been printed both in French and English. One of the best of the French editions is that annotated by M. Guizot, 30 vols. 8vo, 1821-27. (See the *Eloges* on Rollin by Berville, Maillet-Lacoste, and Trognon; also his *Life* by Rivarolle-Etienne and Bousson de Mauret.)

ROLLO, ROLF, or RAOTL, the conqueror of Normandy, was a Norwegian duke, banished from his country by Harold Harfagr (who conquered Norway in A.D. 870) on account of the piracies he committed. He first retired with his fleet among the islands of the Hebrides, to the north-west of Scotland, whither the flower of the Norwegian nobility had fled for refuge ever since Harold had become master of the whole kingdom. He was there received with open arms by those warriors, who, eager for conquest and revenge, waited only for a chief to undertake some glorious enterprise. Rollo, placing himself at their head, and seeing his power formidable, sailed towards England, which had long been a field open on all sides to the violence of the northern nations. But the great Alfred had some years before established such order in his part of the island that Rollo, after several fruitless attempts, despaired of forming there such a settlement as should make him amends for the loss of his own country. He pretended, therefore, to have had a supernatural dream, which promised him a glorious fortune in France, and which served at least to support the ardour of his followers. The weakness of the government in that kingdom, and the confusion in which it was involved, were still more persuasive reasons to insure them of success. Having therefore sailed up the Seine to Rouen, he immediately took the capital of the province then called Neustria (subsequently *Normandy*), and making it his magazine of arms, he advanced and laid siege to Paris. The entire cession of Neustria was the result, which Charles the Simple was obliged to give up to Rollo and his Normans in order to purchase a peace. Rollo received it in perpetuity to himself and his posterity as a feudal duchy dependent on the crown of France. A description of the interview between Charles and this new duke gives us a curious picture of the manners of these Normans; for the latter would not take the oath of fealty to his sovereign lord any other way than by placing his hands within those of the king; and absolutely refused to kiss his feet, as custom then required. It was with great difficulty that he was prevailed on to let one of his warriors perform this ceremony in his stead; but the officer to whom Rollo deputed this service suddenly raised the king's foot so high, that he overturned him on his back, a piece of rudeness which was only laughed at; to such a degree were the Normans feared and Charles despised. Rollo was soon afterwards persuaded to embrace Christianity, and he was baptized with much ceremony, under the name of Robert, by the Archbishop of Rouen, in the cathedral of that city, in the year 912. As soon as he saw himself in full possession of Normandy, he exhibited such virtues as rendered the province happy, and deserved to make his former outrages forgotten. Religious, wise, and liberal, this captain of pirates became, after Alfred, the greatest and most humane prince of his time. He seems to have died about 927. Ordericus Vitalis assigns his death to 917. There is published by Duchesne, in his *Historia Normannorum Scriptores Antiqui* the panegyric of Dean Dudo of St Quentin upon the first three dukes of Normandy, viz., Rollo, William I., surnamed Longue-Epée, and Richard, surnamed Sans-Peur.

ROLLOCK, ROBERT, the first principal of the university of Edinburgh, was the son of David Rollock of Powis, in the neighbourhood of Stirling, and was born in the year 1555. He enjoyed the instructions of Thomas Buchanan, a man distinguished for worth and learning, and a nephew of the great George Buchanan. From school he was sent to the university of St Andrews, where his progress was

Rollo

Rollock.

||
Romagnosi.

so rapid that he was made professor of philosophy soon after he took his master's degree. The magistrates of Edinburgh having petitioned the king to found a university in that city, they obtained a charter, by which they were allowed all the privileges of a university, which was built in 1582, and Rollock was chosen principal and professor of divinity. In the year 1593 Rollock and others were appointed by Parliament to confer with the Popish lords; and in 1595 he was empowered, along with others, to visit the different universities in Scotland, with a view to inquire into the doctrine and practice of the different masters, the discipline adopted by them, the state of their rents and living, which they were ordered to report to the next General Assembly. He was chosen moderator of the General Assembly in the year 1597. The greater part of his life was spent in conducting the affairs of the church; yet Spottiswood assures us that he would rather have preferred retirement and study. Indeed the feebleness of his constitution was not equal to the bustle of public life. He died at Edinburgh on the last day of February 1598, in the forty-third year of his age. Short as his life was, he published many works, chiefly in Latin. A particular account of the author will be found in a volume printed under the following title:—*De Vita et Morte Roberti Rollok, Academiæ Edinburgensæ Primarii, Narrationes, auctoribus Georgio Robertson et Henrico Charteris*, Edinb. 1826, 4to. Robertson's biographical tract was originally published in 1599; that of Charteris was printed from a manuscript in the public library of the university for the use of the Bannatyne Club. An edition of the *Select Works* of Robert Rollock was published in Edinburgh under the auspices of the Wodrow Society, and under the editorship of William M. Gunn, 2 vols., 1849. The editor has translated the biography by Charteris, with elucidatory notes. He has likewise given at the end of the biography a list of the author's writings.

ROMA, COMARCA DI, a province of the Papal States, bounded on the E. by the kingdom of Naples, S. by the delegation of Frosinone and legation of Velletri, E. by the Mediterranean and the delegation of Civita Vecchia, and N. by those of Viterbo and Rieti; area, 1715 square miles. The north-eastern part of the country is occupied by the branches of the Sabine and Tuscan Apennines, among which there are many tracts of great picturesqueness and beauty. The principal summits are Monte Guadagnolo; Monte Genaro, the ancient *Lucretilis*, 4185 feet high; and Monte San Oreste, the ancient *Soracte*, about 2000 feet. The principal river in the province is the Tiber, which flows from N.E. to S.W. into the Mediterranean, and it receives from the left the Teverone, anciently called the *Anio*. Some smaller streams flow into the sea; and there are several lakes, such as those of Albano, Bracciano, and Neri, which occupy ancient volcanic craters. The most of the country belongs to the gently-undulating tract called the Campagna di Roma, many parts of which are liable to malaria. Pop. (1856) exclusive of the city, 150,507.

ROMAGNOSI, GIAN DOMENICO, an eminent publicist, was born in 1761, near Piacenza, and studied jurisprudence at Parma. His treatise on the *Origin of Penal Law*, published in 1791, was the beginning of his success. It is true that at first his own countrymen did not recognise the merits of his work. But the French, who gained a footing in Italy by the victory of Marengo, had become acquainted with his talents, and a series of important appointments was the consequence. He was made professor of jurisprudence in 1802 at the university of Parma. He was appointed one of the commission in 1806 for compiling a code of criminal procedure. He was translated in 1807 to the chair of civil law at Pisa. At length he was called to Milan in 1809 to lecture on legislative science. The latter part of Romagnosi's life, however, was attended by

Romaine
||
Romana.

embarrassing circumstances. The general suppression of special chairs of law in 1817 deprived him of his situation. The scantiness of his savings obliged him to have recourse to private teaching. In the midst of his work a shock of paralysis impaired his strength. The Austrian government also kept a suspicious eye upon all his movements. He was thus forced to live in poverty and cautious obscurity till his death in 1835. Besides the work already mentioned, another important production of Romagnosi's is an *Introduction to the History of Universal Public Law*, in 2 vols. 8vo, Parma, 1806. His complete works were published in 5 vols. 8vo, Florence, 1834.

ROMAINE, WILLIAM, a pious English divine, was born at Hartlepool in Durham in 1714, and was educated for the church at Oxford. No sooner had the young man received orders than he appeared in the character of a Calvinist. The long time which he was compelled to drag out as a country curate did not make him adapt his creed to the principles of the dispensers of ecclesiastical promotion. After he had settled in London in 1748 his consistency came out more prominently than ever. So emphatically did he preach the doctrine of justification by faith alone, that on several occasions he found himself opposed in an outrageous manner by his superiors. During his career as lecturer at St Dunstan's-in-the-West, he was frequently denied the use of lights, and was obliged to hold a candle in one hand while he gave effect to his sermon with the other. In 1755 he was deprived of his office of morning preacher at St George's, Hanover Square, after he had officiated for four years with great success. In 1757 he was refused admission to the university pulpit at Oxford on account of a discourse which he had formerly delivered there on the text, "The Lord our righteousness." It was not until he had been appointed, in 1764, to the rectory of St Ann's, Blackfriars, that he was allowed to discharge his ministerial functions without any violent opposition. Romaine died in 1795. His works, consisting of sermons, letters, and religious pamphlets, accompanied with a memoir, were published by the Rev. W. B. Cadogan, in 8 vols. 8vo, London, 1796.

ROMAN CATHOLICISM, the name applied by Protestants to that large section of Christians which regard the Bishop or Pope of Rome as its infallible spiritual head, and which assumes to itself the title of Catholic or Universal. Its principal doctrines have already been given under the heads MASS, POPE, POPERY, PURGATORY, &c. Under the article REFORMATION is given a rapid sketch of the successful struggles made by various of the European states to deliver themselves from the domination of the Pope.

ROMANA, DON PEDRO CARO Y SUREDA, a Spanish general, was born at Majorca in 1761, and was trained to the profession of arms. In 1808 he was advancing the French interests in Fuen at the head of a Spanish force, when the intelligence reached him that the crown of his native kingdom had been given to Joseph Bonaparte. He immediately began to take measures for saving his country. With the utmost secrecy his troops were collected and embarked. Placing them under the command of Count San Roman, he sent them off to vindicate the rights of their lawful sovereign. He himself then repaired to London, to solicit the aid of England against the French. Nor was his task of patriotism finished when he had gained the object of his mission, and had returned to Spain. As commander-in-chief of the provinces of Biscay, Galicia, and Asturias, he assisted the British both by his counsels and by his operations. So notable, indeed, were his services, that on his death in 1811, the Duke of Wellington said that "in him the Spanish army had lost its finest ornament, Spain its purest patriotism, and the world the bravest and the most zealous defender of the cause for which we combat."

ROMANCE.

Romance.
Definition
and origin
of the word
romance

DR. JOHNSON has defined Romance, in its primary sense, to be "a military fable of the middle ages; a tale of wild adventures in love and chivalry." But although this definition expresses correctly the ordinary idea of the word, it is not sufficiently comprehensive to answer our present purpose. A composition may be a legitimate romance, yet neither refer to love nor chivalry—to war nor to the middle ages. The "wild adventures" are almost the only absolutely essential ingredient in Johnson's definition. We would be rather inclined to describe a *Romance* as "a fictitious narrative in prose or verse; the interest of which turns upon marvellous and uncommon incidents;" being thus opposed to the kindred term *Novel*, which Johnson has described as "a smooth tale, generally of love;" but which we would rather define as "a fictitious narrative, differing from the romance, because the events are accommodated to the ordinary train of human events, and the modern state of society." Assuming these definitions, it is evident, from the nature of the distinction adopted, that there may exist compositions which it is difficult to assign precisely or exclusively to the one class or other; and which, in fact, partake of the nature of both. But the distinction will be found broad enough to answer all general and useful purposes.

The word Romance, in its original meaning, was far from corresponding with the definition now assigned. On the contrary, it signified merely one or other of the popular dialects of Europe, founded, as almost all these dialects were, upon the Roman tongue, that is, upon the Latin. The name of romance was indiscriminately given to the Italian, to the Spanish, even, in one remarkable instance at least,¹ to the English language. But it was especially applied to the compound language of France; in which the Gothic dialect of the Franks, the Celtic of the ancient Gauls, and the classical Latin, formed the ingredients. Thus Robert De Brunne:

"All is calde geste Inglis,
That en this language spoken is—
Frankis speech is caled *Romance*
So sayis clerkis and men of France."

At a period so early as 1150, it plainly appears that the Romance language was distinguished from the Latin, and that translations were made from the one into the other; for an ancient romance on the subject of Alexander, quoted by Fauchet, says it was written by a learned clerk,

"Qui de Latin la trest, et en Roman la mit."

The most noted romances of the middle ages were usually composed in the romance or French language, which was, in a peculiar degree, the speech of love and chivalry; and those which are written in English always affect to refer to some French original, which usually, at least, if not in all instances, must be supposed to have a real existence. Hence, the frequent recurrence of the phrase,

"As in romance we read;"

Or,

"Right as the romaunt us tells;"

and equivalent phrases, well known to all who have at any time perused such compositions. Thus, very naturally,

though, undoubtedly by slow degrees, the very name of romance, or romance, came to be transferred from the language itself to that peculiar style of composition in which it was so much employed, and which so commonly referred to it. How early a transference so natural took place, we have no exact means of knowing; but the best authority assures us, that the word was used in its modern sense so early as the reign of Edward III. Chaucer, unable to sleep during the night, informs us, that, in order to pass the time,

"Upon my bed I sate upright;
And bade one reehin me a hoke,
A ROMAUNCE, and it me took
To read and drive the night away."

The book described as a romance contained, as we are informed,

"——— Fables
That clerkis had, in old time,
And other poets, put in rhyme."

And the author tells us a little lower,

"This book ne spake but of such things,
Of Queens' lives and of Kings"

The volume proves to be no other than Ovid's *Metamorphoses*; and Chaucer, by applying to it the name of romance, sufficiently establishes that the word was, in his time, correctly employed under the modern acceptation.

Having thus accounted for the derivation of the word, our investigation divides itself into three principal branches, though of unequal extent. In the first of these we propose to inquire into the general history and origin of this peculiar species of composition, and particularly of romances relating to European chivalry, which necessarily form the most interesting object of our inquiry. In the second, we shall give some brief account of the history of the romance of chivalry in the different states of Europe. Thirdly, we propose to notice cursorily the various kinds of romantic composition by which the ancient romances of chivalry were followed and superseded, and with these notices to conclude the article.

I. In the views taken by Hurd, Percy, and other older General authorities, of the origin and history of romantic fiction, their history of attentions were so exclusively fixed upon the romance of romance. chivalry alone, that they appear to have forgotten that, however interesting and peculiar, it formed only one species of a very numerous and extensive genus. The progress of romance, in fact, keeps pace with that of society, which cannot long exist, even in the simplest state, without exhibiting some specimens of this attractive style of composition. It is not meant by this assertion, that in early ages such narratives were invented, in the character of mere fictions, devised to beguile the leisure of those who had time enough to read and attend to them. On the contrary, romance and real history have the same common origin. It is the aim of the former to maintain as long as possible the mask of veracity; and indeed the traditional memorials of all earlier ages partake in such a varied and doubtful degree of the qualities essential to those opposite lines of composition, that they form a mixed class between them; and may be termed either romantic histories, or historical romances,

¹ This curious passage was detected by the industry of Ritson in *Giraldus Cambrensis*, "*Ab aqua illa optima, quæ Scottice vocato est Faoth; Brittanice, Wfrid; Romane vero Scotte-Wattre.*" Here the various names assigned to the Frith of Forth are given in the Gaelic or Earse, the British or Welsh; and the phrase *Roman* is applied to the ordinary language of England. But it would be difficult to shew another instance of the English language being termed Roman or Romance.

Romance. according to the proportion in which their truth is debased by fiction, or their fiction mingled with truth.

A moment's glance at the origin of society will satisfy the reader why this can hardly be otherwise. The father of an isolated family, destined one day to rise into a tribe, and in further progress of time to expand into a nation, may, indeed, narrate to his descendants the circumstances which detached him from the society of his brethren, and drove him to form a solitary settlement in the wilderness, with no other deviation from truth, on the part of the narrator, than arises from the infidelity of memory, or the exaggerations of vanity. But when the tale of the patriarch is related by his children, and again by his descendants of the third and fourth generation, the facts it contains are apt to assume a very different aspect. The vanity of the tribe augments the simple annals from one cause; the love of the marvellous, so natural to the human mind, contributes its means of sophistication from another; while, sometimes, the king and the priest find their interest in casting a holy and sacred gloom and mystery over the early period in which their power arose. And thus altered and sophisticated from so many different motives, the real adventures of the founder of the tribe bear as little proportion to the legend recited among his children, as the famous hut of Loretto bears to the highly ornamented church with which superstition has surrounded and enchased it. Thus the definition which we have given of Romance as a fictitious narrative turning upon the marvellous or the supernatural, might, in a large sense, be said to embrace

quicquid Græcia mendax
Audet in historia,

or, in fine, the mythological and fabulous history of all early nations.

It is also important to remark, that poetry, or rather verse, rhythm at least of some sort or other, is originally selected as the best vehicle for these traditional histories. Its principal recommendation is probably the greater facility with which metrical narratives are retained in the memory, a point of the last consequence, until the art of writing is generally introduced; since the construction of the verse itself forms an artificial association with the sense, the one of which seldom fails to recall the other to recollection. But the medium of verse, at first adopted merely to aid the memory, becomes soon valuable on account of its other qualities. The march or measure of the stanza is gratifying to the ear, and, like a natural strain of melody, can be restrained or accelerated, so as to correspond with the tone of feeling which the words convey; while the recurrence of the necessary measure, rhythm or rhyme, is perpetually gratifying the hearer by a sense of difficulty overcome. Verse being thus adopted as the vehicle of traditional history, there needs but the existence of a single man of genius, in order to carry the composition a step higher in the scale of literature than that of which we are treating. In proportion to the skill which he attains in his art, the fancy and ingenuity of the artist himself are excited; the simple narrative transmitted to him by ruder rhymers is increased in length; is decorated with the graces of language, amplified in detail, and rendered interesting by description; until the brief and barren original bears as little resemblance to the finished piece, as the *Iliad* of Homer to the evanescent traditions, out of which the blind bard wove his tale of Troy Divine. Hence, the opinion expressed by the ingenious Percy, and assented to by Ritson himself. When about to present to his readers an excellent analysis of the old romance of *Lybius Disconius*, and making several remarks on the artificial management of the story, the Bishop observes, that "if an epic poem may be defined a fable related by a poet to

excite admiration and inspire virtue, by representing the Romance. action of some one hero favoured by Heaven, who executes a great design in spite of all the obstacles that oppose him, I know not why we should withhold the name of *epic poem* from the piece which I am about to analyse."¹

Yet although this levelling proposition has been laid down by Percy, and assented to by Ritson (writers who have few opinions in common,) and although, upon so general a view of the subject, the *Iliad*, or even the *Odyssey* of Homer, might be degraded into the class of romances, as *Le Beau Deconnu* is elevated into that of epic poems, there lies in ordinary speech, and in common sense, as wide a distinction between these two classes of composition, as there is betwixt the rude mystery or morality of the middle ages, and the regular drama by which these were succeeded. Where the art and the ornaments of the poet chiefly attract our attention; where each part of the narrative bears a due proportion to the others, and the whole draws gradually towards a final and satisfactory conclusion; where the characters are sketched with force, and sustained with precision; where the narrative is enlivened and adorned with so much, and no more, of poetical ornament and description, as may adorn, without impeding its progress; where this art and taste are displayed, supported, at the same time, by a sufficient tone of genius, and art of composition, the work produced must be termed an epic poem, and the author may claim his seat upon the high and honoured throne occupied by Homer, Virgil, and Milton. On the other hand, when a story languishes in tedious and minute details, and relics for the interest which it proposes to excite, rather upon the wild excursions of an unbridled fancy, than upon the skill of the poet; when the supernatural and the extraordinary are relied upon exclusively as the supports of the interest, the author, though his production may be distinguished by occasional flashes of genius, and though it may be interesting to the historian, as containing some minute fragments of real events, and still more so to the antiquary, from the light which it throws upon ancient manners, is still no more than a humble romancer, and his work must rank amongst those rude ornaments of a dark age, which are at present the subject of our consideration. Betwixt the extremes of the two classes of composition, there must, no doubt, exist many works, which partake in some degree of the character of both; and after having assigned most of them, each to their proper class, according as they are distinguished by regularity of composition and poetical talent, or, on the contrary, by extravagance of imagination, and irregularity of detail, there may still remain some, in which these properties are so equally balanced, that it may be difficult to say to which class they belong. But although this may be the case in a very few instances, our taste and habits readily acknowledge as complete and absolute a difference betwixt the epopeia and romance, as can exist betwixt two distinct species of the same generic class.

We have said of romance, that it first appears in the form of metrical history, professes to be a narrative of real facts, and is, indeed, nearly allied to such history as an early state of society affords; which is always exaggerated by the prejudices and partialities of the tribe to which it belongs, as well as deeply marked by their idolatry and superstition. These it becomes the trade of the romancers still more to exaggerate, until the thread of truth can scarce be discerned in the web of fable which involves it; and we are compelled to renounce all hope of deriving serious or authentic information from the materials upon which the compounders of fiction have been so long at work, from one generation to another, that they have at length obliterated the very shadow of reality or even probability.

The view we have given of the origin of romance will be

¹ *Reliques of Ancient English Poetry*, III. xxvii. The Prelate is citing a discourse on epic poetry, prefixed to *Telemachus*.

Romance. found to agree with the facts which the researches of so many active investigators of this curious subject have been able to ascertain. It is found, for example, and we will produce instances in viewing the progress of romance in particular countries, that the earliest productions of this sort, known to exist, are short narrations or ballads, which were probably sung on solemn or festive occasions, recording the deeds and praises of some famed champion of the tribe and country, or perhaps the history of some remarkable victory or signal defeat, calculated to interest the audience by the associations which the song awakens. These poems, of which very few can now be supposed to exist, are not without flashes of genius, but brief, rude, and often obscure, from real antiquity or affected sublimity of diction. The song on the battle of Brunanburgh, preserved in the *Saxon Chronicle*, is a genuine and curious example of this aboriginal style of poetry.

Temporal and spiritual romances.

Even at this early period,¹ there may be observed a distinction betwixt what may be called the *Temporal* and *Spiritual* romances; the first destined to the celebration of worldly glory; the second to recording the deaths of martyrs and the miracles of saints; both which themes unquestionably met with an almost equally favourable reception from their hearers. But although most nations possess, in their early species of literature, specimens of both kinds of romance, the proportion of each, as was naturally to have been expected, differs according as the genius of the people amongst whom they occur leaned towards devotion or military enterprise. Thus, of the Saxon specimens of poetry, which manuscripts still afford us, a very large proportion is devotional, amongst which are several examples of the spiritual romance, but very few, indeed, of those respecting warfare or chivalry. On the other hand, the Norman language, though rich in examples of both kinds of romances, is particularly abundant in that which relates to battle and warlike adventure. The Christian Saxons had become comparatively pacific, while the Normans were certainly accounted the most martial people in Europe.

However different the spiritual romance may be from the temporal in scope and tendency, the nature of the two compositions did not otherwise greatly differ. The structure of verse and style of composition was the same; and the induction, even when the most serious subject was undertaken, exactly resembled that with which minstrels introduced their idle tales, and often contained allusions to them. Warton quotes a poem on the Passions, which begins,

I hereth one lutele tale, that Ich eu wille telle,
As wi vyndeth hit invrite in the godspelle,
Nuz hit nouht of Carlemeyne ne of the Duzpere,
Ac of Criste's thruurynge, &c.

The temporal romances, on the other hand, often commenced by such invocations of the Deity, as would only have been in place when a much more solemn subject was to be agitated. The exordium of the Romance of *Ferumbras* may serve as an example of a custom almost universal;

God in glorie of mightis moost
That all things made in sapience,
By virtue of Word and Holy Gooste,
Giving to men great excellence, &c.

The distresses and dangers which the knight endured for the sake of obtaining earthly fame and his mistress's favour, the saint or martyr was exposed to for the purpose of securing his rank in heaven, and the favour of some beloved and peculiar patron saint. If the earthly champion is in peril from monsters, dragons, and enchantments, the spiritual hero is represented as liable to the constant assaults of the whole invisible world, headed by the ancient dragon himself. If the knight is succoured at need by some favouring fairy or

Romance. protecting genius, the saint is under the protection not only of the whole heavenly host, but of some one divine patron or patroness who is his especial auxiliary. Lastly, the conclusion of the romance, which usually assigns to the champion a fair realm, an abundant succession, and a train of happy years, consigns to the martyr his fane and altar upon earth, and in heaven his seat among saints and angels, and his share in a blessed eternity. It remains but to say, that the style and language of these two classes do not greatly differ, and that the composers of both employ the same structure of rhythm and of language, and draw their ideas and their incidents from similar sources; so that, having noticed the existence of the spiritual romance, it is unnecessary for the present to prosecute this subject farther.

Another early and natural division of these works of fiction seems to have arranged them into *Serious* and *Comical* romances.

The former were by far the most numerous, and examples of the latter are in most countries comparatively rare. Such a class, however, existed, as proper romances, even if we hold the comic romance distinct from the *Contes* and *Fabliaux* of the French, and from such jocular English narratives as the *Wife Lapt in Moral's Skin*, *The Friar and the Boy*, and similar humorous tales; of which the reader will find many examples in Ritson's *Ancient English Poetry*, and in other collections. The scene of these *gestes* being laid in low, or at least in ordinary life, they approach in their nature more nearly to the class of novels, and may perhaps be considered as the earliest specimens of that kind of composition. But the proper comic romance was that in which the high terms and knightly adventures of chivalry were burlesqued, by ascribing them to clowns or others of a low and mean degree. Such compositions formed, as it were, a parody on the serious romance, to which they bore the same proportion as the antimasque, studiously filled with grotesque, absurd, and extravagant characters, "entering," as the stage direction usually informs us, "to a confused music," bore to the masque itself, where all was dignified, noble, stately, and harmonious.

An excellent example of the comic romance is the *Tournament of Tottenham*, printed in Piercy's *Reliques*, in which a number of clowns are introduced practising one of these warlike games, which were the exclusive prerogative of the warlike and noble. They are represented making vows to the swan, the peacock, and the ladies; riding a tilt on their clumsy cart horses, and encountering each other with ploughshares and flails; whilst their defensive armour consisted of great wooden bowls and troughs, by way of helmets and cuirasses. The learned editor seems to have thought this singular composition was like Don Quixote, with which he compares it, a premeditated effort of satire, written to expose the grave and fantastic manners of the serious romance. This is considering the matter too deeply, and ascribing to the author a more critical purpose than he was probably capable of conceiving. It is more natural to suppose that his only ambition was to raise a laugh, by ascribing to the vulgar the manners and exercises of the noble and valiant; as in the well-known farce of *High Life Below Stairs*, the ridicule is not directed against the manners described, but against the menials who affect those that are only befitting their superiors. The *Hunting of the Hare*, published in the collection formed by the late industrious and accurate Mr. Weber, is a comic romance of the same order. A yeoman informs the inhabitants of a country hamlet that he has found a hare sitting, and invites them to come to course her. They attend, accordingly, with all the curs and mastiffs of their village, and the unsportsman-like manner in which the inexperienced huntsmen and their irregular pack conduct themselves, forms the interest of the piece. It can hardly be supposed the satire is directed against the sport of hunt-

¹ The religious romances of *Barlaam* and *Jehoshaphat* were composed by John of Damascus in the eighth century.

Romance. ing itself; since the whole ridicule arises out of the want of the necessary knowledge of its rules, incident to the ignorance and inexperience of the clowns who undertook to practise an art peculiar to gentlemen. The ancient poetry of Scotland furnishes several examples of this ludicrous style of romantic composition; as the *Tournament at the Drum*, and the *Justing of Watson and Barbour*, by Sir David Lindsay. It is probable that these mock encounters were sometimes acted in earnest; at least King James I. is accused of witnessing such practical jests; "sometimes presenting David Dioman and Archie Armstrong, the king's fool, on the back of other fools, to tilt at one another till they fell together by the ears."—(Sir Anthony Weldon's *Court of King James*.)

Classical romances. In hastily noticing the various divisions of the romance, we have in some degree delayed our promised account of its rise and progress; an inquiry which we mean chiefly to confine to the romance of the middle ages. It is indeed true that this species of composition is common to almost all nations, and that even if we deem the *Iliad* and *Odyssey* compositions too dignified by the strain of poetry in which they are composed to bear the name of metrical romances; yet we have the pastoral romance of *Daphnis and Chloe*, and the historical romance of *Theagenes and Chariclea*, which are sufficiently accurate specimens of that style of composition. The *Milesian fables* and the romances of Antonius Diogenes, described by Photius, could they be recovered, would also be found to belong to the same class. It is impossible to avoid noticing that the Sybarites, whose luxurious habits seem to have been intellectual, as well as sensual, were peculiarly addicted to the perusal of the Milesian fables; from which we may conclude that they were not of that severe kind which inspired high thoughts and martial virtues. But there would be little advantage derived from extending our researches into the ages of classical antiquity respecting a class of compositions which, though they existed then, as in almost every stage of society, were neither so numerous nor of such high repute as to constitute any considerable portion of that literature.

Eastern romances. Want of space also may entitle us to dismiss the consideration of the Oriental romances, unless in so far as in the course of the middle ages they came to furnish materials for enlarging and varying the character of the romances of knight-errantry. That they existed early, and were highly esteemed both among the Persians and Arabians, has never been disputed; and the most interesting light has been lately thrown on the subject by the publication of *Antar*, one of the most ancient, as well as most rational, if we may use the phrase, of the Oriental fictions. The Persian romance of the *Shah-Nameh* is well known to Europeans by name, and by copious extracts; and the love-tale of *Mejnoun and Leilah* is also familiar to our ears, if not to our recollections. Many of the fictions in the extraordinary collection of the *Arabian Tales* approach strictly to the character of romances of chivalry; although in general they must be allowed to exceed the more tame northern fictions in dauntless vivacity of invention, and in their more strong tendency to the marvellous. Several specimens of the comic romance are also to be found mingled with those which are serious; and we have the best and most positive authority that the recital of these seductive fictions is at this moment an amusement as fascinating and general among the people of the East, as the perusal of printed romances and novels among the European public. But a minute investigation into this particular species of romance would lead us from our present field, already sufficiently extensive for the limits to which our plan confines it.

The European Romance, wherever it arises, and in whatsoever country it begins to be cultivated, had its origin in some part of the real or fabulous history of that country; and of this we will produce, in the sequel, abundant proofs.

Romance. But the simple tale of tradition has not passed through many mouths, ere some one, to indulge his own propensity for the wonderful, or to secure by novelty the attention of his audience, augments the meagre chronicle with his own apocryphal inventions. Skirmishes are magnified into great battles; the champion of a remote age is exaggerated into a sort of demi-god; and the enemies whom he encountered and subdued are multiplied in number, and magnified in strength, in order to add dignity to his successes against them. Chaunted to rhythmical numbers, the songs which celebrate the early valour of the fathers of the tribe become its war-cry in battle, and men march to conflict hymning the praises and the deeds of some real or supposed precursor who had marshalled their fathers in the path of victory. No reader can have forgotten that when the decisive battle of Hastings commenced, a Norman minstrel, Taillefer, advanced on horseback before the invading host, and gave the signal for onset, by singing the *Song of Roland*, that renowned nephew of Charlemagne, of whom romance speaks so much, and history so little; and whose fall, with the chivalry of Charles the great in the pass of Roncesvalles, has given rise to such clouds of romantic fiction, that its very name has been for ever associated with it. The remarkable passage has been often quoted from the *Brut of Wace*, an Anglo-Norman metrical chronicle.

Taillefer, qui moult bien chantout
Sur un cheval qui tost alout,
Devant le Duc alout chantant
De Karlemaigne et de Rollant,
Et d'Oliver et des vassals,
Qui morurent en Rennevals.

Which may be thus rendered :

Taillefer, who sung both well and loud,
Came mounted on a courser proud;
Before the Duke the minstrel sprang,
And loud of Charles and Roland sung,
Of Oliver and champions mo,
Who died at fatal Roncevaux.

This champion possessed the sleight-of-hand of the juggler, as well as the art of the minstrel. He tossed up his sword in the air, and caught it again as he galloped to the charge, and showed other feats of dexterity. Taillefer slew two Saxon warriors of distinction, and was himself killed by a third. Ritson, with less than his usual severe accuracy, supposed that Taillefer sung some part of a long metrical romance upon Roland and his history; but the words *chanson*, *cantilena*, and *song*, by which the composition is usually described, seems rather to apply to a brief ballad or national song; which is also more consonant with our ideas of the time and place where it was chaunted.

But neither with these romantic and metrical chronicles did the mind long remain satisfied; more details were demanded, and were liberally added by the invention of those who undertook to cater for the public taste in such matters. The same names of kings and champions, which had first caught the national ear, were still retained, in order to secure attention, and the same assertions of authenticity, and of reference to real history, were stoutly made both in the commencement and in the course of the narrative. Each nation, as will presently be seen, came at length to adopt to itself a cycle of heroes like those of the *Iliad*; a sort of common property to all minstrels who chose to make use of them, under the condition always, that the general character ascribed to each individual hero was preserved with some degree of consistency. Thus, in the romances of *The Round Table*, Gawain is usually represented as courteous; Kay as rude and boastful; Mordred as treacherous; and Sir Launcelot as a true though a sinful lover, and in all other respects a model of chivalry. Amid the Paladins of Charlemagne, whose cycle may be considered as peculiarly the property of French in opposition to Anglo-Norman ro-

Romance. mance, Gan, or Ganelon of Mayence, is always represented as a faithless traitor engaged in intrigues for the destruction of Christianity; Roland as brave, unsuspicious, devotedly loyal, and somewhat simple in his disposition; Renaud, or Rinaldo, is painted with all the properties of a borderer, valiant, alert, ingenious, rapacious and unscrupulous. The same conventional distinctions may be traced in the history of the Nibelung, a composition of Scandinavian origin, which has supplied matter for so many Teutonic adventurers. Meister Hildebrand, Etzel, Theodorick, and the champion Hogan, as well as Chrimhelda and the females introduced, have the same individuality of character, which is ascribed, in Homer's immortal writings, to the wise Ulysses, the brave but relentless Achilles, his more gentle friend Patroclus, Sarpedon, the favourite of the gods, and Hector, the protector of mankind. It was not permitted to the invention of a Greek poet to make Ajax a dwarf, or Teucer a giant, Thersites a hero, or Diomedes a coward; and it seems to have been under similar restrictions respecting consistency that the ancient romancers exercised their ingenuity upon the materials supplied them by their predecessors. But, in other respects, the whole store of romantic history and tradition was free to all as a joint stock in trade, on which each had a right to draw as suited his particular purposes. He was at liberty not only to select a hero out of known and established names which had been the theme of others, but to imagine a new personage of his own pure fancy, and combine him with the heroes of Arthur's Table or Charlemagne's Court, in the way which best suited his fancy. He was permitted to excite new wars against those bulwarks of Christendom, invade them with fresh and innumerable hosts of Saracens, reduce them to the last extremity, drive them from their thrones, and lead them into captivity, and again to relieve their persons, and restore their sovereignty, by events and agents totally unknown in their former story.

In the characters thus assigned to the individual personages of romantic fiction, it is possible there might be some slight foundation in remote tradition, as there were also probably some real grounds for the existence of such persons, and perhaps for a very few of the leading circumstances attributed to them. But these realities only exist as the few grains of wheat in the bushel of chaff, incapable of being winnowed out, or cleared from the mass of fiction with which each new romancer had in his turn overwhelmed them. So that romance, though certainly deriving its first original from the pure fount of history, is supplied, during the course of a very few generations, with so many tributes from the imagination, that at length the very name comes to be used to distinguish works of pure fiction.

When so popular a department of poetry has attained this decided character, it becomes time to inquire who were the composers of these numerous, lengthened, and once admired narratives which are called metrical romances, and from whence they drew their authority. Both these subjects of discussion have been the source of great controversy among antiquaries; a class of men who, be it said with their forgiveness, are apt to be both positive and polemical upon the very points which are least susceptible of proof, and which are least valuable if the truth could be ascertained; and which, therefore, we would gladly have seen handled with more diffidence, and better temper, in proportion to their uncertainty.

The late venerable Dr. Percy, Bishop of Dromore, led the way unwarily to this dire controversy, by ascribing the composition of our ancient heroic songs and metrical legends, in rather too liberal language, to the minstrels, that class of men by whom they were generally recited. This excellent person, to whose memory the lovers of our ancient lyre must always remain so deeply indebted, did not, on publishing his

work nearly fifty years ago, see the rigid necessity of observing the utmost and most accurate precision either in his transcripts or his definitions. The study which he wished to introduce was a new one; it was his object to place it before the public in an engaging and interesting form; and, in consideration of his having obtained this important point, we ought to make every allowance not only for slight inaccuracies, but for some hasty conclusions, and even exaggerations, with which he was induced to garnish his labour of love. He defined the minstrels, to whose labours he chiefly ascribed the metrical compositions on which he desired to fix the attention of the public, as "an order of men in the middle ages, who subsisted by the arts of poetry and music, and sung to the harp verses composed by themselves or others."¹ In a very learned and elegant essay upon the text thus announced, the reverend Prelate in a great measure supported the definition which he had laid down; although it may be thought that, in the first editions at least, he has been anxious to view the profession of the minstrels on their fairest and most brilliant side; and to assign to them a higher station in society than a general review of all the passages connected with them will permit us to give to a class of persons who either lived a vagrant life, dependent on the precarious taste of the public for a hard-earned maintenance, or, at best, were retained as a part of the menial retinue of some haughty baron, and in a great measure identified with his musical band.

The late acute, industrious, and ingenious Mr. Joseph Ritson, whose severe accuracy was connected with an unhappy eagerness and irritability of temper, took advantage of the exaggerations occasionally to be found in the Bishop's *Account of Ancient Minstrelsy*, and assailed him with terms which may be termed any thing but courteous. Without finding an excuse either in the novelty of the studies in which Percy had led the way, or in the vivacity of imagination which he did not himself share, he proceeded to arraign each trivial inaccuracy as a gross fraud, and every deduction which he considered to be erroneous as a wilful untruth, fit to be stigmatised with the broadest appellation by which falsehood can be distinguished. Yet there is so little room for this extreme loss of temper, that, upon a recent perusal of both these ingenious essays, we were surprised to find that the reverend editor of the *Reliques*, and the accurate antiquary, have differed so very little as, in essential facts, they appear to have done. Quotations are, indeed, made by both with no sparing hand, and hot arguments; and, on one side at least, hard words are unsparingly employed; while, as is said to happen in theological polemics, the contest grows warmer in proportion as the ground concerning which it is carried on is narrower and more insignificant. Their systems, in reality, do not essentially differ.
